The methods which must nowadays be used by the scientific investigator are many and often very complicated. Even if his inquiries are limited to medicine and physiology he has very frequently to obtain the help of the chemist, the physicist, and the instrument maker. The designing of scientific instruments is both a science and a trade, and though wonderful things have been done in the past with very simple appliances, yet the need for an instrument of absolute precision is very often felt. It can only be met by the co-operation of the experimenter and the instrument maker, and both need trustworthy information as to what has been done by others. The field of research is so wide that few can keep up with the possibilities of new methods and instruments, and it is often difficult to obtain definite information as to their construction, capabilities and limitations. Sir Richard Glazebrook, when Director of the National Physical Laboratory, realized the growing importance of the subject to the well-being of science and industry, and issued a circular letter to many men of science, Government departments, societies, trade associations and firms, asking for opinions as to the desirability of founding a journal to deal with methods of measurement and with instruments. The answers were encouraging, and the subject was taken up by the Board of the Institute of Physics. As a result of a conference between the Advisory Council for Scientific and Industrial Research, the Institute of Physics, and the present Director of the National Physical Laboratory, it was resolved to prepare a preliminary number of a *Journal of Scientific Instruments*, and this is now before us. It opens with a note by Sir J. J. Thomson, President of the Institute of Physics and late President of the Royal Society. He observes that descriptions of instruments and methods of measurement are commonly given in journals devoted to particular branches of science, and that in such publications results are of primary importance, so that little space can be afforded to descriptions and detailed drawings of instruments. He goes on to point out that instrumental methods frequently proved to be valuable for research of quite a different character from that for which they were designed, and that therefore there is a need for a journal dealing with methods of measurement, and the theory, construction, and use of instruments. Among the papers contained in the preliminary number is one by Dr. A. V. Hill, professor of physiology in the University of Manchester, dealing with instruments and apparatus in relation to progress in physiology. In it he enumerates some of the physiological inquiries for which instruments of precision are necessary. The sueness to which measurements must be carried in some of the instances he gives is almost bewildering; for instance, he observes: "The nervous impulse in man travels some 100 metres per second, and the electric change

(which is its only known physical accompaniment) occupies at any moment only some 5 cm. of the nerve. This electric wave, of an amplitude 0.01 to 0.02 volt, lasts therefore only some 0.0005 second at any point." His article is, indeed, largely concerned with electrical apparatus, but he also considers microscopical methods and speaks of the microscope as at present "a very imperfect tool in view of what physiology really requires of it." Nevertheless, he points out that Bayliss has been able to show, with the aid of intense dark-ground illumination, that the apparently clear pseudopodia of *Amoeba* are filled with numerous minute particles in Brownian movement, which movement can suddenly be stopped by electric stimulation. A further advance may, he hopes, follow the application to microscopical technique of such physical methods as the use of short ultra-violet light and higher magnification, the further development of instantaneous photography, or a more accurate knowledge of how far stains and fixatives produce artificial effects. Other articles, some of them from laboratories of manufacturing firms, are concerned with instruments used in astronomy, surveying, and flight. If this preliminary number elicits sufficient promises of support the new journal will be produced monthly by the Institute of Physics. The editorial staff will be provided by the National Physical Laboratory, and the editor will be assisted by a scientific advisory committee appointed by the Institute of Physics. It is recognized, however, that the help of biologists, engineers, chemists, and instrument makers, as well as physicists, will be necessary on this committee to ensure the proper consideration of apparatus used in the different branches of science. It is estimated that with a circulation of about 1,000 there will be a deficit of some £2,000 per annum, while a circulation of about 3,000 will render the journal self-supporting. If established, each issue will probably consist of 32 pages, and the price of each number will be 2s. 6d. Anyone desirous of obtaining a copy of the preliminary issue, which it has been possible to issue owing to a grant from the Advisory Council for Scientific and Industrial Research, may apply to the Secretary of the Institute of Physics, 10, Essex Street, London, W.C.2, enclosing 6d. to cover postage.

MEDICAL WOMEN'S FEDERATION.

At the half-yearly meeting of the council of the Medical Women's Federation, held in London on May 8th and 9th, when Lady Barrett, the newly elected president, was in the chair, a long discussion took place on a report from a sub-committee on venereal diseases. A report was received also from a subcommittee on international relations, which had been appointed about a year ago in consequence of the great development of international health bodies in connexion with the League of Nations and otherwise. The subcommittee brought forward a scheme for an international organization of medical women on representative lines; this was approved by the council and will be brought before a conference of delegates from various countries, to be held next September at Geneva under the auspices of the American International Association of Medical Women. Reports from representatives of the Federation on outside bodies, including those relating to six committees of the British Medical Association, to the National Council for Combating Venereal Diseases, and to the College of Preceptors' Subcommittee on Physical Education of Girls, were received. In connexion with the report from the representative on the Insurance Acts Committee of the British Medical Association the following motion was passed: "The Council of the Medical Women's Federation is of opinion that the National Insurance Acts Committee should be strongly supported in their efforts to prevent the approved societies gaining control of the medical officers of the Insurance Acts." The Council also had under consideration several fresh instances of inequality of pay, or of status, between men and women doing the same work. This inequality still persists in the Post Office, in spite of repeated representations both from the Federation and the British Medical Association. Though the Postmaster-General has refused to receive a

deputation on the subject, the Council decided to make further effort to redress these inequalities and to uphold vigorously the principle of "equal pay for equal work"; it was resolved also to continue energetically the campaign carried on by a standing committee of the Council against the policy which would render married medical women ineligible for public appointments or lead to their dismissal merely on the ground that they were married. An official request from the League of Nations for the nomination by the Federation of a medical woman to be elected a member of the Health Committee of the League of Nations was complied with.

FOOT AND MOUTH DISEASE.

THE Ministry of Health has addressed a circular letter to local sanitary authorities with regard to a recent amendment of the Foot and Mouth Disease Order of the Ministry of Agriculture, which modifies the hitherto invariable practice of dealing with local outbreaks by the slaughter of all animals found to be suffering from the disease or to have been in contact with diseased animals. In future each case will be considered on its merits, and where local circumstances are specially favourable for securing isolation, or when large herds of great value are concerned, the policy of keeping affected animals and contacts in strict isolation until their recovery may be considered. Where this new procedure is adopted the responsibility of ensuring that the milk from the diseased animals is not sold for human consumption will fall upon the sanitary authority. The amended order provides for notifying the medical officer of health of all outbreaks of foot and mouth disease amongst animals in his district and for informing him whenever it is proposed to deal with the diseased animals and contacts by isolation under the Dairies, Cowsheds, and Milkshops Order (1885). It will therefore be a practical point for him to determine at what stage of convalescence the milk can be regarded as innocuous. Many cases have been reported in which illness in man has followed direct or indirect infection from animals suffering from the disease; most of the cases have occurred in outbreaks following the consumption of milk from affected cows. Some of these outbreaks lack evidence of specificity, but in a certain number of them the symptoms described by different observers have presented a remarkably uniform clinical picture closely resembling the disease in animals. They include aphthae on the mouth, fingers, and toes, accompanied by pyrexia. The disease in man is usually described as running a mild course followed by recovery in a week or ten days. Three of the epidemics described by Siegel¹ in Germany and Austria, however, had a high fatality. In this country only a few outbreaks and isolated cases of a suspicious nature have been reported; none have been encountered in recent years, nor has any suspicious illness been reported in connexion with the present outbreak. The crucial experiment of successfully transmitting the disease from man to calf by inoculation has been reported on two occasions, by Schantyr² and by Bertarelli.³ There can be little doubt, therefore, that foot and mouth disease can be transmitted to man. In view of these facts the question arises why the disease is not more commonly found in human beings, especially in connexion with such an extensive outbreak as that which has prevailed recently in this country. Innumerable opportunities for the infection of man must have occurred during this period, for, although the protection afforded by the Ministry of Agriculture's policy of slaughter must be considerable, there is evidence that the milk is infectious in the very early stages of the disease, and probably for some days before the appearance of the typical lesions. The complete immunity which our population seems to have experienced from any infection of the sort during this epidemic suggests very forcibly that the infectivity to man of the type of disease prevailing in Britain must be very low. In other parts of Europe also cases of supposed

foot and mouth disease in man were very rarely reported down to 1872, but in that year the disease in cattle assumed a malignant form, and human cases came to be reported much more frequently about this time. On account of the marked variation in the virulence and certain other features of foot and mouth disease some authorities are inclined to regard it as comprising two separate entities. The form which has been observed of late years in this country, including the recent considerable outbreak, has been of the mild type, and this may account for the absence of human cases. Opportunities for estimating the mortality among cattle from this type of disease in England have not been afforded owing to the policy of slaughter hitherto enforced. In South America, however, where the disease is allowed to run its natural course, the mortality is much greater during those seasons of the year when fresh grass and green fodder are not available, and when the animal's food is restricted to hard and dry forage, which leads to wasting and death from starvation owing to the lesions produced by the disease in the animal's mouth. In favourable seasons, on the other hand, comparatively few animals are lost as a result of foot and mouth disease. Reports of Continental outbreaks show a mortality varying from 2 to 50 per cent.

COLOUR VISION TESTS.

A MEDICAL man has written to us about the case of an officer in the mercantile marine who failed to pass the lantern test for a master's certificate, but who (our correspondent believes) is not colour blind. There is no doubt that in the past many candidates with normal vision have failed to pass the Board of Trade tests for colour perception, and also that others with dangerous errors of colour perception have qualified. It is important to remember that there are grades of colour perception, which vary from mere colour weakness to complete lack of colour appreciation. Some of these errors are of academic interest only. For example, a man who confuses green and blue may be quite safe both at sea and on the foot-plate, whereas one who has the slightest doubt between red, green, and white must be at once rejected. Again, a person with perfect colour perception may have shortening of the red end of the spectrum; such a man is unable to see a red light in circumstances when the red light is obvious to the normal-sighted. The theories of colour vision are many; they are confused, and it may be that all are wrong; but the practice is quite clear. If a man is shown a small red or green or white light and betrays the slightest difficulty in naming it he must be rejected; it does not matter what label is given to his error, he is dangerous. The exact type of colour blindness he is suffering from may be determined by other tests—by the flicker test, the Rayleigh equation test, or by one of the numerous pigment tests, such as Nagel's or Stilling's, but these are all subsidiary. The man has to distinguish between red, green, and white lights, and to do so under very adverse conditions. If in the quiet of the examiner's room he is shown a bright red light and calls it "white," or if he calls an adequate green light "red" or "white," he must be rejected. Again, if he names them all correctly and yet fails to perceive red covered with a neutral glass—a dim red light clearly visible to the examiner—then again he will be rejected. We can imagine nothing more logical or rational than a test of this type. By it the candidate is examined upon what he has to do in his daily work.

SCIENTIFIC SECTIONS AT THE GLASGOW ANNUAL MEETING.

THE officers of the Section of Dermatology at the forthcoming Annual Meeting of the British Medical Association in Glasgow have arranged the following provisional programme: On Wednesday, July 26th, there will be a discussion on "The etiology of seborrhoea and seborrhoeic dermatitis"; the opening paper will be given by Dr. Cranston Low, and the discussion will be introduced by Dr. Harold W. Barber. On July 27th Dr. W. J. O'Donovan will open a discussion on "Occupational dermatitis"; shorter papers will be read by

¹ Zeit. f. Klin. Med., 1897, p. 147.

² Archiv. Veterinärch. Nauch., 1893, p. 87.

³ Centralbl. f. Bakt., 1908, v. 628.

Dr. G. H. Lancashire on "Dermatitis artefacta," and by Professor J. Goodwin Tomkinson on "Alopecia areata and strabismus, a family group of cases." Clinical demonstrations will also be arranged for both days, probably at 9 a.m. The Section of Laryngology meets on Thursday, July 27th, and the officers have arranged as the subject for discussion, "Diseases of the oesophagus, their symptomatology and differential diagnosis"; the openers will be Dr. D. R. Paterson of Cardiff and Mr. W. G. Howarth of London. The officers of the Section of Diseases of Children have made the following preliminary arrangements: On July 26th there will be a joint discussion with the Section of Physiology on the "Etiology of rickets," opened by Dr. Leonard Findlay and Professor Mellaub. On July 27th a discussion on the "Treatment of tuberculous cervical glands" will be introduced by Mr. John Fraser. Clinical demonstrations will be held in the afternoon of both days at the Royal Hospital for Sick Children: on July 26th Mr. Alex. McLennan will give a demonstration there on scoliosis, and on the 27th Mr. Alexander Mitchell will show skiagrams of regeneration of bone in osteomyelitis. The Section of Radiology and Electrolgy will meet on two days, and the officers of the Section have arranged the following provisional programme: On July 26th, a discussion on "The x-ray treatment of deep-seated cancers, with special reference to Erlangen methods," to be opened by Dr. J. R. Riddell; a paper by Dr. J. A. Longley on "Comparison of coil and high-tension transformer in x-ray therapy," and a discussion on "The value of gas inflation in x-ray diagnosis," to be opened by Dr. F. Herniman-Johnson. On July 27th, papers by Dr. H. E. Gamlen, Dr. C. W. S. Saberton, Dr. James Crockett, Dr. E. W. Reed, and Dr. J. Gibson Graham. These papers will be followed by a discussion on "The therapeutic value of high-frequency currents and static electricity," to be opened by Dr. E. P. Cumberland, Dr. F. Howard Humphris, and Dr. W. F. Soucerville. In the Section of Ophthalmology Dr. L. Webster Fox of Philadelphia will read a paper on "The clinical significance and treatment of heterophoria." The officers of the Section of Surgery announce that the full titles of all papers which it is proposed to read at the Annual Meeting should be intimated to the honorary secretaries of the Section before June 15th, when the full programme will be definitely arranged. The names of the officers of the nineteen Sections, with the programmes so far as these had been arranged, were published in the *SCIENTIFIC* of May 13th, at p. 173. The Sections will meet on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th.

INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE.

As already announced in these columns, the Third International Congress of the History of Medicine will be held in London this summer from July 17th to 22nd. The programme of the week's proceedings has now been drawn up and printed. The Congress will be opened by the Minister of Health at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, on Monday, July 17th, at 10.30 a.m., after which the delegates from foreign countries will be received, and the president, Dr. Singer, will give his address. In the afternoon the President of Honour, Sir Norman Moore, Bt., will give a reception and address at the Royal College of Physicians; in the evening there will be a reception and conversation by Dr. and Mrs. Singer at the Royal Society of Medicine, and an address by Professor Elliot Smith. Morning sessions for papers and discussions will be held at 1, Wimpole Street—the headquarters of the Congress—on Tuesday, Wednesday, Thursday, and Friday, and afternoon sessions on Tuesday, Thursday, and Friday. Receptions will be given on Tuesday afternoon by the Lord Mayor and Lady Mayoress, at the Mansion House; on Tuesday evening by Sir James Parves Stewart and Lady Stewart, at 94, Harley Street; on Wednesday afternoon by the President of the Royal College of Surgeons of England, at the College; and on Thursday evening by Mr. and Mrs. H. J. Waring, at 37, Wimpole Street. On Wednesday afternoon visits to

Barbers' Hall and Apothecaries' Hall have been arranged, and in the evening there will be a conversation at the Wellcome Historical Medical Museum, where a special loan exhibition will be on view. On Friday afternoon Sir D'Arcy Power will give an historical address at St. Bartholomew's Hospital, and in the evening a banquet will be held at the Hotel Cecil. On Saturday Hampton Court Palace will be visited. Those wishing to become members of the Congress are asked to communicate as early as possible with the General Secretary, Dr. J. D. Rolleston (21, Alexandra Mansions, King's Road, S.W.3) or the Treasurer, Mr. W. G. Spencer, O.B.E., M.S. (2, Portland Place, W.1). Members desiring to read communications at the Congress should write to Dr. Rolleston before May 31st. The printed programme gives a list of hotels, with their tariffs, at which accommodation can be reserved if booked before July 1st.

TELEPHONES.

Among the changes in telephonic charges and arrangements which are to come into force on July 1st are certain alterations described as "considerable concessions" which have been made with regard to the terms on which new exchanges will be opened in rural areas. The alterations, though not very generous, possess a certain interest for members of the medical profession practising in the country, and may eventually prove to be the most important of all the changes to be made if they can be taken as an indication that the Post Office is beginning to realize that its policy with regard to telephones in rural areas has been mistaken. Hitherto the difficulties put in the way of establishing new exchanges have been great and the cost excessive; the service, therefore, has not been good. A too costly system can, in fact, hardly be made a good one, since the more installations in any area the greater the effective value of the telephone system in that area. There should be at least one or two installations in every village. In respect to rural telephones this country is much behind some others, especially perhaps Switzerland, Canada, and the United States; there installations in villages and country houses are the rule and not the exception. When the use of telephonic installations is general the time of country doctors is saved and their efficiency thereby increased. The Postmaster-General admitted in the House of Commons that the present charges are prohibitive, amounting in a great number of cases to a rental of as much as £20 a year. That the rural public feel the need for telephones is shown by the fact that even under the old conditions 530 call offices were opened last year at provincial post offices, chiefly in rural districts, and 3,293 stations on rural lines. Under the new scheme it is announced that an exchange will in future be opened provided eight subscribers renting direct lines can be found, and providing the cost of the necessary junction circuit is not excessive; the installation rental will be £3 a year in addition to extra mileage. There will be a charge of £1 a furlong for any distance in excess of one mile from the new exchange. Where as many as fifteen subscribers can be found the installation rental is to be £7 10s. for business connexions and £6 for connexions to residences. Subscribers will be required to enter into an agreement for three or five years, according to the amount of the capital the Post Office finds it necessary to lay out in making the extension. As a rule service will be provided at these rural exchanges between 8 a.m. and 8 p.m. on week-days, and for a shorter period on Sundays. A continuous service is, however, contemplated when the necessary arrangements can be made, though at present an addition will be made to the installation rental to cover the cost. The Postmaster-General expressed the hope that the reductions now announced would result in a rapid extension of the rural telephone system; but if this expectation is to be realized facilities must be increased and rates diminished. Of the other alterations one of the chief is that the installation rental for a connexion to a residence where no business of any kind is carried on will be reduced by 30s. a year—to £7 in London, £6 10s. in Birmingham, Liverpool, Manchester,

and Glasgow, and £6 elsewhere. The charge for a local call will be reduced from 1½d. to 1d.; the charge for a call over a distance between five and seven and a half miles will remain as at present; but for calls over longer distances 2d. instead of 3d. will be added to the trunk charge. The charges for short-distance trunk calls have been reduced, and in futuro the local fee will not be charged on any trunk calls. The result will be that the charge for a three-minute call over distances up to thirty-five miles will be ½d. less than at present, and for calls over greater distances 1½d. less. At present calls between 7 p.m. and 7 a.m. are in most cases charged at half the full rates; in future the charges between 2 p.m. and 7 p.m. will also be reduced, the new charges being approximately 25 per cent. less than at present. Finally, the extra mileage charge will be reduced from £1 5s. to £1 1s. 6d. a furlong, and a similar reduction will apply to external extensions and to private telephone wires.

VENEREAL DISEASE INQUIRY.

In our issue of April 22nd (p. 655) we published correspondence between Lord Dawson and the Minister of Health regarding the appointment of a committee to inquire into certain aspects of the problem of venereal disease with a view to an authoritative pronouncement on its medical and medico-administrative aspects. The committee was constituted as follows: Lord Evershed, late Lord Chief Justice of England (Chairman), Mr. T. J. Tomlin, K.C. (Vice-Chairman), Mr. C. J. Bond, F.R.C.S., Surgeon Commander Reginald Bond, R.N., Dr. John Brownlee, Professor W. Bulloch, M.D., F.R.S., Dr. D. S. Davies, Professor G. Dreyer, M.D., F.R.S., Dr. F. E. Fremantle, M.P., Dr. Dorothy Hare, Professor H. R. Kenwood, M.D., Sir William Leishman, F.R.S., Dr. F. N. K. Menzies, Sir Frederick Mott, M.D., F.R.S., Dr. J. H. Sequeira, Dr. B. H. Spilsbury, and Mr. Kenneth Walker, F.R.C.S. The terms of reference are: "To consider and report upon the best medical measures for preventing venereal disease in the civil community having regard to administrative practicability, including cost." Lord Dawson in his letter to Sir Alfred Mond stated that he and the other members of the Committee of Selection, which had been formed to select the members of the Committee of Inquiry, were in complete agreement that after the latter committee has reported the community as a whole must decide how far its recommendations can be made the basis of policy and action. The first meeting of the Committee of Inquiry is being held at the close of this week at the Ministry of Health, and it is announced that Dr. Morna Rawlins and Wing-Commander Martin W. Flack, Director of Medical Research, R.A.F., have been added to its number.

THE ASSOCIATION OF CERTIFICATED BLIND MASSEURS.

We are informed that there are members of the Association of Certificated Blind Masseurs resident at the present time in Australia, New Zealand, Canada, and South Africa, and it may be of interest to readers there to be reminded of some facts with regard to the association. It is registered under the Board of Trade, its president is Sir Robert Jones, K.B.E., F.R.C.S., and its vice-presidents include many other distinguished members of the medical profession. Its members, who are for the most part soldiers blinded in the war, have been trained in massage, remedial gymnastics, and medical electricity at St. Dunstan's Hostel for Blinded Soldiers and at others. National Institute for the Blind, London. The training took place over a period of two years, during which they received both theoretical and practical instruction, the latter in receipt of the departments of various London hospitals. The massage department, in which the students are trained, possesses a series of models from the study of which the student can get an idea of the structure and position of the various organs, and special attention is given to surface anatomy. Further, a series of raised diagrams are available, illustrating such points as cerebral localization, and the various tracts of the spinal cord. There is also a library of massage literature in embossed type directed by a blind medical man who has been trained in the art. All the members of the Association have passed the examination of the Association of Massage.

and Medical Gymnasts under exactly the same conditions as sighted candidates. We believe that the medical profession may thoroughly rely upon the competence of blind masseurs belonging to the association.

PROFESSOR OF PSYCHIATRY, SYDNEY.

DR. JOHN MACPHERSON, C.B., who has lately retired from the post of Commissioner of the Board of Control for Scotland, has been offered through the Agent-General of New South Wales, and has accepted for a period of three years, the post of Professor of Psychiatry in the University of Sydney. This chair is the first of its kind in any university in Australia. The university authorities were particularly anxious to appoint to this post a physician of authority and of experience, and it is a compliment to the Edinburgh school that they have selected one who is so closely connected with it. Dr. Macpherson for some years lectured on the subject of mental diseases at the Royal Colleges' School of Medicine. His clinical knowledge was acquired at the Royal Hospital at Morningside and at the Stirling District Asylum. Few have had such experience as he in administration. There is already a clinic on mental diseases in connexion with the hospital at Sydney, and it is anticipated that Professor Macpherson will bring the teaching and other arrangements abreast of the latest advances that have been made in the science and practice of psychiatry.

SIR STCLAIR THOMSON will give, on Wednesday, May 24th, at 5 p.m., the next lecture in the new series of post-graduate lectures arranged by the Fellowship of Medicine at the house of the Royal Society of Medicine, 1, Wimpole Street, W. The subject selected is, "The surgical anatomy of the nose and accessory sinuses." The lecture, which will be illustrated by a lantern demonstration, is open to members of the medical profession.

SIR ALFRED KEOGH, G.C.B., is retiring from the office of Rector of the Imperial College of Science and Technology, South Kensington, under the age rule, at the end of the summer term. He will be succeeded by Sir Thomas Holland, K.C.S.I., F.R.S., an old student of the College, who saw much service in India, and was Professor of Geology and Mineralogy at Manchester University from 1909 to 1918. Sir Alfred Keogh, although he has held the office for a good many years, was not able to discharge its duties with the completeness he and all friends of scientific education had hoped. As is well known, he was called back to act as Director-General of the Army Medical Service soon after the war began and was not relieved from his military duties until 1918.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Reduction of Service Establishments.

THE Army Orders issued by the War Office on May 11th as to disposal of officers on reduction of the army establishment have interest for the Royal Army Medical Corps, because in so far as any reductions in medical personnel may be made the schedule will have application to the medical officers, if and when reductions are made, as well as to others. The list gives scales of compensation allowance and of gratuities for combatant officers.

Experiments on Animals.

Commander Kenworthy sought leave, on May 10th, "to introduce a bill to prevent the application of public money to vivisection experiments." He claimed that this was a practical attempt at economy. There was nothing in the measure to prevent vivisection experiments being continued at the hand of any learned societies or others who provided the money. His contention was that in these times it was not right that public money should be granted for this purpose, especially as part of it must come from persons who had scruples about vivisection. The sum was, he believed, substantial. Before the war the amount spent on medical research was approximately £60,000. It was now over £120,000, of which a considerable sum was spent on these experiments. He believed the figures to be round about £30,000 or £40,000.

MEDICAL TERMS IN THE VERNACULAR AND IN DIALECTS.

II.

ANDICOMB, ANCOME, UNCOME, OR INCOME.

ADAM LITTLETON, in his *Latin Dictionary* (1678), gave andicomb as one of the meanings of the word *clavus*: "a corn in the finger or toe, or sole of the foot; a little swelling of hard flesh in the corner of the eye; also a whitlow or andicomb." Now since the agnail or agnail of a former article was found sometimes to be used as synonymous with whitlow one might at first sight regard andicomb as yet another vernacular term signifying an agnail. It is so, but only to the extent of being an additional name for whitlow. Andicomb itself, however, is quite an interesting medical term as used by the common people, and is worthy of separate consideration.

Sir James Murray, in the *New English Dictionary*, did not place andicomb among the A rubrics, and neither did Wright in the *English Dialect Dictionary*; but under *ancome* the former lexicographer gave "andicomb" as an eighteenth-century form of that word, and he said that the spellings *ancomb* and *andicomb* showed that the term was no longer understood. Even the word "ancome" he classified as obsolete or dialectal. So one is left with the unexplained emergence of "andicomb" in English in the later centuries and its rapid disappearance again, and one is tempted to conclude that it came from the dialects and returned to the dialects. It would be easy to find a plausible enough etymology for it; one might see in it a reminiscence of the ordinary meaning of hangnail and regard it as made up of hand and comb, with the suggestion of comb-like teeth or fleshy projections attached to the fingers of the hand. There is, however, nothing more dangerous than attractive pseudo-etymology; it will be in every way wiser to follow Sir James Murray in his conclusion that *andicomb* is simply another form of *ancome*.

Ancome, with its sixteenth and seventeenth century form "uncome," and its seventeenth-century "ancombe," is traced by Murray to the Northern English "on-come" (fourteenth century), meaning "visitation, access of disease." He admits that this is only a probability, and suggests as an alternative that it is a partially translated adaptation of the Norse word *akoma*, which signifies "arrival, visitation, eruption of the skin." From this "on-come," with such a meaning, could be traced the sixteenth-century "uncome," and it would also be capable of being refashioned into the Scottish and North of England "income." This identification of "-come" with the idea of arrival, introduction from the outside, and so forth, is borne out by several of the quotations.

For instance, Sir Thomas Elyot, writing in 1538 (and it must be remembered that he had read medical works with "a worshipful physician," and that he wrote on medical subjects, thereby arousing some wrath on the part of the profession of his day), defined the word we are studying as "*adventitius morbus*, syeknes that cometh without our defaute, . . . of some men called an uncome." John Baret, too, the Cambridge lexicographer, who about 1574 published "*An Alvearie*" (a beehive!), "or Triple Dictionary in English, Latin, and French," gave the following definition: "a fellon, uncome, or eates haire; a bile or sore that riseth in mans bodie, *furunculus*;" and again, in another place, "an ancome, *adventitius morbus*." Murray quotes also from an Act of Henry VIII (1544) the phrase "uncomes of hands, scaldings, burnings." One begins to see how the ideas of something coming in and a furunculus, felon, whitlow, boil, or the like are not irreconcilable; a sliver of wood or something else runs into the finger and so an ancome arrives, if one may speak so tautologically.

Philemon Holland—who, it will be remembered, was a "doctor of physick" as well as a schoolmaster in Coventry—in his translation of Pliny's *Natural History* (1601) used the word "uncome" several times and always to render the Latin *furunculus* (boil), and he sometimes added "fellow" as a synonym. Thus in one passage he wrote, "also when we perceive a fellow or such like uncom sore a breeding, the first thing that we doe is to marke it three times with our fasting spittle"; and in another he stated about a certain ointment, "it is singular good for any uncome or fellow." Gerarde, in his *Herball* (1636), used uncome in meanings such as also, in his writing of the arsmart or water pepper, these given; thus, in writing of the bound upon an impostume he stated, "the same bruised and bound upon an impostume

fellow or uncome) for the space of an houre, taketh away the paine." Gerarde was "Master in Chirurgie" and so may be held qualified to speak on these matters.

Thus one reaches some of the modern definitions—for example, that of Wright (in the *English Dialect Dictionary*), "an ulcerous swelling," or that of Murray, "a boil; an imposthume; by some later writers applied to a whitlow." These agree, too, with the definition of the eighteenth-century lexicographer, John Kersey the younger, who gave "ancome, a kind of boil, sore, or foul swelling in the fleshy parts." Marston, in his comedy, *Eastward Ho*, published in 1605, actually gives the clinical history of the thing: "I have seen a little priek, no bigger than a pin's head, swell bigger and bigger till it has come to an ancome." How close one has come to agnail is shown by the fact that Hexham in his *Dictionary* defines the Dutch word *vijf* as "an Ancombe, or Sore upon one's finger"; and Köhler, in his *German Dictionary*, gives three English equivalents for *Nagelgeschwür*—namely, whitlow, agnail, felon. Bailey (1778) adds two characters to the ancome, "a swelling or bump, that is hard and hot"; but they were already implicit in the earlier definitions.

Jamieson, in his *Scottish Dictionary*, deals with the Northern corresponding term "income"; but his definition does not at first glance agree with the conclusions reached above, for he has "any bodily infirmity not apparently proceeding from an external cause," and he gives an illustrative quotation from Galt's *Sir A. Wyllie*: "her wheel was no longer of any use to her, for she had got an income of her left arm, and couldna spin." There may be real agreement, however, for he explains that "the affection, as it were, came in, as not being caused by a sprain, a contusion, a fall, or anything of this nature." The cause was originally introduced from without—for example, from a splinter of wood—but the results were developed within; but it must be confessed Jamieson is not clear on this matter. Quotations from Scottish writers later than Jamieson suggest some disease of the knee or at least of a joint, and Wright states that in Caithness it is used with the meaning of "disease in a joint, usually knee or elbow, which causes it to be permanently bent"; but if this be the Caithness use then the Northumberland one is different, for there it signifies "an ulcer, something that has come in from an outside cause as distinguished from 'a gathering' caused by internal bad blood, which is called 'bred-venom.'" Yet, notwithstanding these uses, Wright has followed Jamieson in his definition, which is, "an internal disease, a bodily infirmity not due to accident or contagion, an ailment without apparent external cause, frequently an abscess, boil, or running sore." It is evident that "income," whilst it may sometimes correspond exactly with the Southern ancome and uncome, does not do so constantly. Possibly the new shade of meaning is due to the thoughts suggested by "in."

The relations of andicomb, ancome, uncome, and income having been traced both in the vernacular and in the dialects, it will be worth while to return to the Northern English word "on-come," with which Sir James Murray has connected them all. It does not appear to have been used in any of the specific senses that ancome, uncome, and income have acquired, but always with the general meaning of a calamity or a visitation or (in Scotland) an attack of disease. Thus, in the *Cursor Mundi*, that extraordinarily interesting rhyming Bible interspersed with legends of the saints and stories from the apocryphal gospels, which was written in Northumbria about the time when Baunockburn was being fought, the visitation of Pharaoh is predicted in these words: "And for that he wil noght me here, Hard oncome sal i send him sere." In one of the MSS. "hardenesses" appears instead of "on-come." In another place the author, in speaking of the plague of frogs, said: "the tother oncome atte him felle was frokis atte na said: 'the tother oncome atte him felle was frokis atte na tunge mote tel,'" and one of the MSS. reads "vengeance." In another passage "on-fall" is the word, and that is reminiscent of the Scottish "on-ding" (for example, of snow). It is evident, however, that "on-come" in these early days (fourteenth century) had the most general meaning, and it was only as time went on and the vowel changed into an-, un-, or in-time that the special significations of boil, whitlow, fellow, disease introduced from without, and the like, came to be associated with it. This still leaves the mystery of *andicomb* unsolved, and, indeed, one suspects that forgotten dialectal uses would clear up more than one obscure point in the word's history. Meanwhile a rather curious fact emerges: in so recent a medical work as Allbutt's *System of Medicine* "oncome" appears with something very like its old meaning in such

a phrase as "the gradual oncome of chronic renal disease"; but it will not do for the doctor to pretend to know too much about "oncomes," for Sir Walter Scott (in *The Bride of Lammermoor*) assigned this wisdom to Ailsie Gourlay when he wrote, "This woman had acquired a considerable reputation . . . by the pretended cures which she performed, especially in oncoires, as the Scotch call them, or mysterious diseases which baffle the regular physician." J. W. B.

England and Wales.

CAMBRIDGE UNIVERSITY MEDICAL SOCIETY.

The inaugural meeting of the Cambridge University Medical Society was held in the Anatomy School, Cambridge, on May 10th, the lecturer being Dr. W. Langdon Brown, physician to St. Bartholomew's Hospital, who took as his subject "The endocrine glands and their relationship to the sympathetic nervous system." The chair was taken by the president of the society, Mr. E. S. Fellowes-Farrow (Downing), who was supported by the vice-president, Mr. Norman F. C. Burgess (Caius), the honorary secretary, Mr. C. L. Owen (Trinity), and the honorary treasurer, Mr. T. F. McNair Scott (Caius). Introducing the lecturer, the president referred to the great work done by him in helping to bridge the gap between physiology and clinical medicine, and pointed out that it is one of the objects of the society (which is essentially for students) to correlate the work in the physiology and anatomy schools with the work at the bedside. He also took the opportunity of expressing the thanks of the society to the Right Hon. Sir Clifford Allbutt, K.C.B., F.R.S., Professor J. B. Bradbury, Professor F. G. Hopkins, F.R.S., Professor J. N. Langley, F.R.S., and Professor J. T. Wilson, F.R.S., for consenting to become honorary vice-presidents, and for giving the society so much encouragement and support. At the conclusion of Dr. Langdon Brown's lecture, which was greatly appreciated, Dr. W. L. H. Duckworth gave a short lecture on the operation of thyroidectomy.

Sir Clifford Allbutt, Regius Professor of Physic, moved a very cordial vote of thanks to the lecturers. The meeting, at which there was a crowded audience, should be an indication that the new society has before it a future full of success and usefulness.

UNIVERSITY OF LONDON REPORT.

The report of the work of the University of London during the year 1921-22 was presented by the Principal Officer, Sir E. Cooper Perry, M.D., at the graduation ceremonial of the University on May 4th. The total admissions by all channels during the year under review was 7,092, as compared with 3,852 in 1913-14, and 6,723 in 1920-21. The total number of candidates for all examinations was 27,237, as against 11,920 in 1913-14, and 23,563 in 1920-21. While the number of persons who sat for the matriculation and registration examinations was 6,638 in 1913-14, 15,539 in 1920-21, and 17,919 in 1921-22, and the number who sat for the preliminary and intermediate examinations was 3,327 in 1913-14, 6,039 in 1920-21, and 6,522 in 1921-22, yet the number of candidates for first degrees was only 1,636 in 1913-14, 1,522 in 1920-21, and 2,153 in 1921-22 respectively, and those for higher degrees only 171 in 1913-14, 224 in 1920-21, and 302 in 1921-22. The total number of successful candidates at all examinations last year was 9,481, and the number of those who attained degrees and diplomas 2,093, as compared with 8,034 and 1,440 respectively, in 1920-21. The standard of the examinations of London University is indicated by the fact that out of 27,237 candidates, 9,481 passed. It is curious to observe how many persons are apparently content to pass the matriculation and preliminary examinations without proceeding to graduation in either "first" or higher degrees. The roll of internal students now bears 8,753 names, as compared with 4,888 on the corresponding date in 1914, and 7,870 in 1921. The Treasury grant for the year to the University was £16,000, an increase of £8,000 on the figure for 1920-21. From correspondence that has passed between the Senate and the post-graduate medical committee appointed by the Ministry of Health, there appears (says Sir Cooper Perry) to be some prospect of the establishment in the near future, in close association with the University, of a medical school attached to a centrally situated hospital, and devoted solely to post-graduate medical education; and, further, of an

Instituto of State Medicine for instruction in public health, forensic medicine, industrial medicine, and medical ethics and economics. The Rockefeller Foundation has now offered to provide the sum of two million dollars for a school of hygiene, and has acquired a site for the school adjoining that presented by the Government for the new buildings of the University in Bloomsbury.

QUEEN CHARLOTTE'S HOSPITAL.

Lord Howard de Walden presided at the annual meeting of Queen Charlotte's Hospital held on May 9th. It was stated in the report that during the past year 1,729 patients had been treated in the hospital, 2,037 had been attended in their own homes, and there had been 4,603 patients at the ante-natal and child welfare departments. The financial position of the hospital was serious, and an earnest appeal was made for additional support. The report referred to the very large number of entries in the Midwifery Training School. During the year 53 medical students and 47 qualified practitioners attended a course of practical midwifery, and 164 women were trained in midwifery and maternity nursing. Students were received from nearly all the London medical schools and from most of the provincial and Scottish schools.

THE LIVERPOOL MATERNITY HOSPITAL.

At the annual meeting of the Liverpool Maternity Hospital on May 9th the same story of lack of funds interfering gravely with the usefulness of this charity was heard as had been heard at the corresponding meetings of other hospitals in Liverpool. The hospital, it was reported, had been continuously full during the past year, and no fewer than 179 women had been refused admission owing to lack of accommodation. A new hospital had been projected shortly before the war, and there was urgent need of a modern and fully equipped institution capable of meeting the demands of the city. The continued high cost of building had alone prevented execution of the project. The need for better training of medical students and midwives was emphasized by Dr. Musson, who referred to the high death rate in women in childbirth, and said that venereal disease and unskilful midwifery were responsible to a large extent. The financial situation was grave. There was a deficiency of £2,052 during the past year, and the debit balance was now £5,355. Unless new sources of revenue were found the work of the hospital would have to be curtailed. It was suggested that if nevertheless the new hospital were begun, an awakened sense of the obligations of the citizens of Liverpool would come at once apparent in a large accession of new subscribers. Reference was made to the success that had crowned the efforts of those responsible for the hospitals in Glasgow and Leicester; small subscriptions were made weekly by all employees, and it was pointed out that no penny out of every pound earned would bring in a splendid income for the hospitals, and thus relieve the committees of the various institutions so essential to the health of the city from their present clamant financial distress.

A SCHOOL MEDICAL OFFICER'S SALARY.

At a meeting of the Worcester Education Committee last week a letter was received from Dr. Marion Andrews, school medical officer, stating that as the city council had made a deduction from her salary of £500 per annum, which was the minimum sum she could accept under the rules of the British Medical Association, she had regretfully to resign. It was stated that a subcommittee had passed a resolution regretting the necessity for the resignation and expressing a hope that the council would not persist in the reduction. This reduction was made in pursuance of a general reduction in officials' salaries of 10 per cent., and the council gave instructions that any official who did not accept the reduction should be asked to resign. Dr. Andrews pointed out in her letter that the position was now worth £750 if she had not refrained from asking for advances because of the general financial stringency. Dr. E. H. Corder, a member of the committee, said that the rule as to the £500 minimum was made during the war. General practitioners were now being asked to reduce their fees, both panel and private, and he suggested that perhaps the minimum would now be modified. Mr. W. Sharpe said that the matter had been before the finance committee and they had had their attention called to the facts which Dr. Corder had mentioned, and the committee had decided to write to the British Medical Association asking if some reduction of the minimum was acceptable.

MEDICAL EDUCATION IN INDIA.

every civilized country; the door of admission must be narrow, and those only should be admitted who in the opinion of the Council in charge of registration were up to the standard. The larger the area the Council covered the easier it was for it to set up a high standard. He suggested that the question of an All-India Medical Council should be considered, composed of representatives of the provincial Councils, to discuss all problems of medical education. He further suggested an interchange of examiners between the different universities for the purpose of raising and standardizing the qualifications of all.

EMANCIPATION OF INDIAN WOMEN.

The Indian woman is coming out from behind the *purdah* and engaging in philanthropic enterprises of various kinds. Recently at Nagpur one Indian lady provided a house rent free and two other Indian ladies made house-to-house visitations with a collecting list and raised enough money to equip a maternity home and the promise of subscriptions sufficient to keep it up. One lady acted as housekeeper, an Indian woman doctor gave her services free, so that a very simple but efficient little nursing home was started, which already is being taken advantage of by the poor, and, except for menial servants, is entirely managed by voluntary effort. This is an example of what Indian ladies can do and the public spirit they are now showing.

ST. JOHN AMBULANCE AND CHILD WELFARE.

Lady Reading, speaking recently at Delhi, paid a glowing tribute to the work of the centres in reference to maternity and child welfare which she had seen in Calcutta under the auspices of the St. John Ambulance Association. Centres exist in different parts of the city for Indian and Anglo-Indian women and children. Many mothers attend daily; they are instructed in the simple rules of mothercraft, their babies are weighed weekly, and any deviation from health is at once noticed. A medical woman attends twice a week for giving advice, and many cases are followed up by a visit to the home, so enabling the visitor and doctor to keep more in touch with the actual conditions under which the mother and child are living.

Correspondence.

BOVINE ACHONDROPLASIA.

SIR,—In a note on "Bovine achondroplasia" in the *BRITISH MEDICAL JOURNAL* of May 6th, 1922, Dr. F. A. E. Crew asks if scattered areas of cartilage have been found in the adrenals of human achondroplasts such as he has met with in the monstrous calves born of Dexter cows.

The adrenals in a full-term human achondroplastic foetus examined by us were normal in shape and weight, and serial sections of both glands revealed no histological abnormality. In a survey of the rather considerable and scattered literature of this condition as it occurs in man we have found, so far, no record of abnormal changes in the adrenals, though it seems that these organs have rarely been examined histologically. MacCallum (*Johns Hopkins Hosp. Bull.*, 1915, xxvi, 182) says that the adrenals were normal in a female achondroplast 75 years old, and also in a 7 months' foetus. G. Marum (*Frankfurt. Zeit. f. Path.*, 1921, xxiv, 663) likewise could find no changes in an adult female achondroplast.

The impression is that the adrenals are intact in human achondroplasia.—W. O. arc, etc.,

EXCISION OF THE HEAD OF THE FEMUR IN ARTHRITIS DEFORMANS.

SIR,—I do not find it easy to reply briefly to Mr. Blundell Bankart, chiefly because there is little to disagree with in his criticisms. There are, however, several points of difference between us which demand a fuller explanation on my part of the rationale of the criticized operation.

The operation as described in my paper has been evolved with simple excision of the femoral head as its basis. I prefer therefore to retain this title, which to my mind is not illogical. It is true that certain of the technical procedures included are employed in full arthroplasty; these are the remodelling of the stump of the neck and the application of

bone wax. I do not agree with Mr. Bankart that (a) the free exposure of the hip by an antero-external flap and (b) the separation of the great trochanter are features peculiar to arthroplasty of the hip. They are simply steps in the adequate exposure of the hip-joint for any purpose, whether this be simple excision of the hip—as advocated by Mr. Bankart—or the more elaborated excision which is dealt with in my communication. With regard to the question of excision of the capsule, I consider it is essential to cut away a considerable amount, not with the idea of determining the future function, but again to facilitate complete exposure of the deformed head previous to its removal. I think my paper made clear that a severe operation can be used only in carefully selected patients, and from practical experience I do not consider the elaborated excision operation to be unreasonably severe.

Simple "straightforward excision" of the femoral head—in the restricted sense of the term—is not an obsolete operation; provided the after-treatment is correct. I have done it in a number of cases of osteo-arthritis, but I do not consider the classical anterior route is efficient; the exposure is too limited unless the head of the femur is disarticulated, a manoeuvre which I feel should be avoided in these patients. Using the postero-lateral route, the operation can be carried out with a full view, and the head removed quickly and with ease. There is one type of case in which it is especially important to do a "radical" excision of the head, and that is when the opposite hip-joint shows early hypertrophic changes with slight limitation of mobility. Again, in unilateral cases, when the changes are very advanced, the large mushroomed head, when removed as conservatively as possible, leaves a neck which is exceedingly short. It will thus be seen that the expression "excision of the femoral head" is capable of varying degrees of interpretation.

The term "arthroplasty" should be limited to an operation performed in the presence of complete ankylosis of a joint and for nothing else. I have no intention of allowing myself to be responsible for the suggestion that, as applied to the hip-joint, "arthroplasty" and "excision of the head of the femur" are synonymous terms.—I am, etc.,

Manchester, May 9th.

HARRY PLATT.

BONE GRAFTING FOR UNUNITED FRACTURES.

SIR,—Professor Rushton Parker draws attention in your correspondence columns of May 6th to a method of treating ununited fractures by bone grafting which he first described in 1907.

The omission of any reference to this method in the paper read by Mr. Perkins and myself is perhaps excused by the full title of our contribution—namely, "Some observations on bone grafting with special reference to bridge grafts." I think that it is now common ground among those who have had recent experience of this subject, that a definite gap in a long bone cannot be successfully bridged except by the insertion of a graft which makes firm contact with both fragments.

The fifty cases upon which we based our observations were nearly all the result of missile injuries which had caused considerable loss of bone substance; scarring both of the bone-end and surrounding tissues as the result of prolonged suppuration was also present in the majority. Such a condition of affairs involves a complete loss of bone-forming tissue in the gap, and it is only by careful attention to the technique of the grafting operation that success can be obtained with any regularity. In my experience the loose interposition of bone fragments or bone dust in this class of case is practically useless.

The cases quoted by Professor Parker and illustrated in the *Proceedings of the Royal Society of Medicine* are of simple fractures, one of six months' and the other of nine months' duration; the x rays show no bone gap and do not even suggest the presence of a pseudarthrosis. I think it is clear that examples of this nature form no basis upon which to determine the proper method for replacing bone when there has been a definite loss of all bone-forming elements at the seat of injury.

I do not question the efficiency of Professor Parker's method in simple cases, but I feel that it is important to emphasize the necessity, brought home by recent intensive experience, of the firm fixation of the bone implant in the case of bridge grafts.—I am, etc.,

London, W., May 12th.

C. MAX PAGE.

ETIOLOGY AND TREATMENT OF DIABETES.

Sir,—In reply to the points raised by Dr. Barnes and Dr. Cammidge in your issue of May 6th, 1922, relating to our article on the etiology of diabetes, it will be necessary to deal with these points seriatim.

Dr. Barnes's charge relating to any suggested divorce between clinical medicine and laboratory work is erroneous, since all the patients were under careful clinical observation by responsible physicians, at least three of the patients mentioned being under the sole supervision of one of us (A. R.). Such a charge is entirely unwarranted and Dr. Barnes ought to have realized that although the details omitted were necessary for clinical observation the complete narration of all clinical details was quite unnecessary from the standpoint of the paper, and that such complete exposition of these details would have obscured the presentation of the more scientific details and would have produced an unwieldy and unrecadable article. We can state categorically that the finding of the organism was not due to the patient being on any particularly selected diet at the time of the examination, since in several patients the organism was found in the stools at the first examination before dieting had been commenced, in some instances whilst attending as out-patients.

With Dr. Barnes's comments regarding a primary ketosis we are in entire agreement, but we would emphasize the defective storage of glucose as being responsible for the glycosuria rather than the secondary failure of the glucose-burning mechanism. In addition to the acetone effects, however, the action of butyl alcohol must be considered, and in our opinion even more important than either of these is the further fate of the extraordinary diastatic ferment produced by this organism. We could dwell at considerable length upon this, but as our article confined itself to facts, so now do we prefer to postpone the theoretical considerations as to the further rôle of this exogenous ferment pending the completion of further work now in hand. We believe, however, that the due consideration of the action of this ferment extended to the tissues would explain the greater part of those clinical details which Dr. Barnes has charged us with neglecting. Meanwhile we commend to Dr. Barnes's consideration the necessity for a quiet and careful survey of the potentialities of such a ferment. When he has ruminated upon this—as, indeed, we have for an extended period—he will then be in a better position to discuss those clinical details from a standpoint which will make him much better understand facts at present perplexing to him.

Dr. Barnes quotes a diet containing oatmeal, cabbage, and can meat. This diet is much too rich in protein for the free growth of *B. amyloclasticus*. We have tried to grow it on a medium composed largely of cabbage, and find that growth therein is extremely poor: the organism becomes thin, loses its Gram stain, and becomes practically unrecognizable, striking parallel to this poor fermentation in protein-rich media is found in the acetone organism fully described by Hill and in other references quoted in our paper.

Dr. Cammidge refers to Koch's postulates. It is quite true we have not as yet attempted to fulfil Koch's postulates; nor have they been satisfactorily fulfilled in every other disease which the etiological agent is known. To endeavour to complete the animal experiments will be costly and laborious, and this has been left over temporarily pending a suitable research grant being obtained to cover these expenses, since so far the work has been carried out at our own expense. Although these postulates had not been completely established it was obvious that the fermentative activity of this organism produced substances *in vitro* presenting such a striking similarity to the abnormal products present in diabetes as to warrant attention being drawn to it.

We do not agree with Dr. Cammidge's suggestion that this organism is present in the intestines as an effect rather than as a cause of diabetes. An effect of what, may we ask Dr. Cammidge? Can Dr. Cammidge, for instance, state how the reaction of the intestinal contents differs in the diabetic and the normal? Apart from complicating pancreatic disease, in what way do the intestinal contents differ?

In regard to Dr. Cammidge's remarks about "heavy inoculations of the stools," similar inoculations of a pure culture also are necessary to secure a good fermentation, and, as we have indicated, it is probably of great importance to the patient that complete vigorous fermentation is probably rarely complete in the intestine. If Dr. Cammidge could see the results of the fermentation *in vitro* of pure cultures of *B. amyloclasticus* he would recognize the beneficial restrain-

ing influences which certain intestinal organisms exercise over the vigorous action of this bacillus.

We have, however, had least difficulty in isolating this organism from those cases which are most rapidly progressive, and in two of the cases which died somewhat rapidly the organism was found at the first attempt.

Regarding the final part of Dr. Cammidge's letter, so many statements concerning diabetes have been made that almost any deduction can be drawn from them. We have not discussed these in our paper, although we have carefully considered them, since we felt that the only way of cutting the Gordian knot of diabetes was by the incisive action of facts driven hard home. Such a fact the *B. amyloclasticus* will, we believe, prove to be.

Finally, we wish to state, in reply to Dr. Barnes and the Editor, that we were not responsible for the supply of details of the paper for advance publication.—We are, etc.,

Manchester, May 15th.
ARNOLD RENSHAW, M.D.,
THOMAS H. FAIRBROTHER, M.Sc.
We are satisfied on further inquiry that Dr. Renshaw and Mr. Fairbrother are not responsible for the advance publication of summaries of their article in the lay press.

ASTHMA AND THE MENOPAUSE.

Sir,—Dr. Coke's argument (March 18th, p. 455) that there must be a shortage of pituitrin in pregnancy because of "its common favour in the midwifery bag" proves rather the contrary, seeing that pituitrin is occasionally required to be supplied artificially in exceptional cases. Dr. Coke surely does not mean that the administration of pituitrin is necessary or even justified as a routine—normal cases must needs have a sufficient supply of this hormone naturally. Moreover, since Comptes in 1899 first stated that the hypophysis cerebri hypertrophies during pregnancy this has been accepted by all authorities.

As regards Dr. Coke's experience of the extreme rarity of asthma commencing *de novo* in pregnancy, my experience has been the opposite. I had several patients, especially primiparæ, whose first attack of asthma started in early pregnancy, and I have no lesser authority than Professor Do Lee¹ to corroborate my experience. That the thickening of the mucous membranes of the respiratory passages (nose, larynx, and pharynx), which is of very frequent occurrence in pregnancy, is the probable contributory factor in precipitating those attacks of asthma seems only reasonable.

Further, the reason that Dr. Coke has not noticed "any difference for better or worse as regards asthma during the menopause" is simply that the onset of the menopause is usually gradual and there is ample time for the adjustment of the interaction between the endocrine organs, while in pregnancy the cessation of the ovarian and uterine mucosa activities is sudden, and in this respect an artificially produced menopause is analogous to pregnancy.—I am, etc.,

Cape Town, April 14th.

S. E. KARK, M.B., Ch.B.,
L.M.R.C.P.I.

MEASLES AND FRESH AIR.

Sir,—Not the least of the noteworthy advances of medical science during the past thirty years has been the hygienic treatment of measles. The fallacy that cold air and water were the chief enemies has departed, and open windows and cleanliness have become the rule, with the result that, although the disease remains as prevalent as ever, its mortality has very greatly diminished (in Woolwich over 50 per cent.). In view of these incontrovertible facts, it is much to be deplored that a great newspaper like the *Times* should advise mothers that "open windows are a mistake," that warm and moist air is a preventive of the bronchopneumonic complication, and that it is therefore of prime importance to "keep the air of the room moist." Warm, moist air may be useful for alleviating the symptoms of bronchitis in cold and dry weather, but as a routine measure it has a most seriously depressing and injurious effect.

My attention was once called to the occurrence of several deaths from measles in a public institution. On investigation I found that some twenty cases were being treated on the lines recommended by the *Times* medical correspondent; windows were shut and all the cases had steam kettles and tents, with the most disastrous results. The warm, moist climate of the Fiji and Faroe islands did not prevent most

¹ De Lee, *Principles and Pract. of Obst.*, p. 355.
² *Ibid.*, p. 110.

of the population dying of measles. How any responsible medical writer—relying on the opinion of "an old doctor of the writer's acquaintance, who in a long medical life never lost a case"—can venture to scatter broadcast such reactionary and dangerous advice passes my comprehension. Is it simply because the Ministry of Health and most of the Public Health Departments of the country are recommending a quite different method of treating this widespread disease?—*am, etc.,*

SIDNEY DAVIES,
Late M.O.H. Woolwich.

Burkhurst Hill, May 25th.

MANY INVENTIONS.

SIR.—I have been much amused at your futile criticism of my friend Dr. Albert Abrams in your issue of the 5th inst. You very seldom quote from the *Journal of the American Medical Association*, and one might have expected that when you did so you would have chosen a more serious subject than an ignorant tirade against an eminent medical man—against, in my opinion, the greatest genius in the medical profession. Why you should have thus acted I cannot surmise, unless it be to justify yourself in refusing an original and very valuable article by Dr. Abrams. The American critic confessedly knows nothing of Abrams's work, though he acknowledges that he has written voluminously. What has Abrams's birth in San Francisco and his degree from Heidelberg to do with his discoveries? Can no good thing come out of Nazareth?

Dr. Abrams has frequently exposed the methods of the American osteopaths and chiropractors with whom this writer links him, but Abrams has been honest enough to acknowledge the good work which they have done, just as many eminent London surgeons have been honest enough to speak in high terms of Mr. Barker, notwithstanding the fact that a man was struck off the *Medical Register* for administering anaesthetics for him.

Dr. Abrams's blood examinations have long been established facts, and if this writer had been imbued with the spirit of science of which he speaks so glibly, instead of ridiculing methods which he was incapable of understanding, he would have tested Abrams by sending a sample of blood from a patient whose disease he did understand. It would only have cost him 10 dollars, a very modest fee which he could have abstracted from the patient, and I have no doubt if Dr. Abrams were satisfied that he was an honest seeker after truth he would have let him off the fee. Dr. Abrams says: "No diagnostic method is infallible," yet Dr. H. A. Hess, a distinguished surgeon, says: "Dr. Abrams has made fifty examinations of blood for me, and all correct, as far as I can judge." How many of the surgeons in this country could make a similar assertion? Dr. J. Madison Taylor, a man well known in this country as well as in America, says: "The light which Dr. Abrams's researches afford is the largest source of illumination, and I, for one, welcome it with thankfulness."

There is no secrecy about Dr. Abrams's methods. All his works are well known, and whether his theories be accepted or not, there is no honest individual who can refuse to accept his facts. There are hundreds of medical men from all parts of the world who visit his clinic, and they are not all fools or knaves as your colleague would seem to infer. I have never known a pupil of Abrams to speak of him except in the highest admiration. Your American friend tries to be very facetious over the sexuality of numbers, vowels, and consonants, and avers that "if there be any scientific foundation for the marvels that Dr. Abrams so picturesquely features, the scientific world has not yet found it out." When did the scientific world ever find out a new fact until it was discovered? Ignorant ridicule may delay the general acceptance, but it can never kill a new discovery. It always seems to me very deplorable that medical men, in place of leading the van in preventive medicine and in the treatment of disease, have frequently to be forced into new positions.

A good many of Dr. Abrams's instruments can be seen in London and have been seen by many medical men; therefore, there is no excuse for bolstering up an ignorant American fusillade. Dr. Abrams wisely refuses to part with his instruments until he knows that they will be properly used, and that the user is competent to carry out his methods. Imagine a delicate instrument in the hands of your American colleague; Dr. Abrams and his methods would be discredited at once. When at the Hotel Cecil on Wednesday night I said, *Damnant quod non intelligunt*, I was thinking of you and your American friend.

Dr. Abrams's most recent discovery is the analysis of hand-

writing, whereby he tells the sex, race, and disease of the writer. When I first heard of this work I did not think it possible or credible, and I told Abrams so. He replied, "Your very kind letter received, and I note what you say about handwriting. I wish you would make the reactions, which are definite and absolute." In the meantime I had made the reactions, and was soon able to corroborate his findings in every particular. At present I am merely amusing myself with these analyses, but I can readily perceive that they may have very wide applicability, and may eventually be of great importance in forensic medicine. It is not necessary to see the writing which you are analysing, as an assistant can carry out the preliminary details. As far as I am concerned I prefer not to see the writing, as thus the personal equation is entirely eliminated. The other day a medical man, to whom I gave a demonstration, asked me when I was going to publish my results. I told him that at present it was quite sufficient for me to educate myself. When every important member of the community has a wireless telephone in his house and on his person, then medical editors and medical men will begin to perceive that there was more in Abrams's vibrations than was dreamt of in their philosophy. Abrams's discoveries have come to stay, whether you like them or not. —I am, etc.,

Liverpool, May 15th.

JAMES BARR.

* * We are at a loss to know which should be the more admired, Sir James Barr's epistolary style or Dr. Albert Abrams's facts. Those who wish to pursue the matter will find in the *Journal of the American Medical Association* for April 29th, 1922 (p. 1534) a long letter by Mr. Upton Sinclair in praise of Dr. Abrams, together with some additional information supplied by the Editor.

THE GENERAL PRACTITIONER AND THE HOSPITALS REPORT.

SIR.—Dr. J. C. Turnbull, in his letter of May 4th (*BRITISH MEDICAL JOURNAL*, May 13th, p. 783), on the Report on the Organization of Voluntary Hospitals, states: (1) That the report contains no definition of "voluntary" as applied to hospitals; (2) that the scheme of the "tariff patients" allows of contract practice by the hospitals.

On the first point, if he reads paragraphs 6 and 7 he will find a couple of related definitions of voluntary hospitals. If he does not consider these to be definitions, what is to be said to those who assert that they are too definite?

On the second point, if he reads paragraph 14 he will find that contract practice by a hospital is distinctly provided against.

14. *New Para.*: In any schemes for providing hospital benefit by voluntary hospitals, it is undesirable that the hospitals concerned should undertake any insurance risk, i.e., undertake to provide hospital benefit, when required, in return for a periodic payment by an individual or a group of individuals; so that where schemes are set up to provide payment for hospital benefit for specified individuals or groups of individuals, such schemes should be organized not by the hospital, but by some independent body.

No one can prevent a person entering into an arrangement with some person or persons to underwrite the risks attendant upon a failure of health. A father of a family may and does enter into a contract with those who are willing to take such insurance risks. But we can and do object to a hospital constituting itself such an underwriter: it is not the business of the hospital. On the other hand, for a hospital to state the terms on which it will accept patients for definite purposes and to receive the payment arranged for work done is legitimate. That is what paragraph 22 (a) provides. His fear that a hospital management could accept patients under a contributory scheme without the agreement of the profession is surely met by paragraph 39, which provides for the representation of the profession in the management of the hospital. —I am, etc.,

London, W., May 15th.

THE OUTLOOK IN TROPICAL HYGIENE.

SIR.—With reference to the notice accorded my address on "The outlook in tropical hygiene" (not medicine) in the *BRITISH MEDICAL JOURNAL* of May 13th, may I be permitted to point out that the last paragraph of that notice unfortunately conveys an erroneous idea of what I really said. It runs as follows:

"Thanks, however, to the lessons learnt in the past eight years courses of instruction were now open to men and women to qualify as sanitary inspectors in the colonies, and a diploma in sanitary science as applied to the tropics was now available."

What I did say was that there was a great need of establishing a special course of instruction in this country for sanitary inspectors destined for the colonies. So far as I am aware, no diploma in sanitary science as applied to the tropics yet exists for sanitary inspectors. All that has been done in this direction is represented by the certificate granted by the Royal Sanitary Institute to sanitary inspectors who have qualified in the examination on tropical sanitation, which has been recently instituted.

I would also like to point out that the investigations on ankylostomiasis of pigs were carried out in Queensland, not in South Australia, and that, as I stated, work has also been done on this subject by O'Connor in the Ellice Islands.—I am, etc.,

Wellcome Bureau of Scientific Research,
London, N.W., May 12th.

ANDREW BALFOUR.

MARRIED MEDICAL WOMEN WHOSE HUSBANDS ARE ABLE TO SUPPORT THEM.

SIR,—As a married woman whose husband is able to support her I protest most strongly against your Association accepting such an advertisement as the one in to-day's JOURNAL, saying such women are ineligible at St. Pancras as assistant medical officers for maternity and child welfare. It is contrary to law (the Sex Disqualification Act), and it is against the best interests of the profession, which no sex jealousy should be allowed to interfere with. In my opinion, with conceit if you like, women with experience of their own children are infinitely better fitted for this work than single women; however much better individual men or women without that experience may be, the former can speak with authority.

We hear a deal about waste these days; surely it is a waste for women to spend so much on qualifying and then (as in my own case, when her children are of school age) stay at home and do another woman out of a job, which she is probably much better at than oneself, and which personally I loathe with a deadly hatred. Looking after one's children when young is a different matter.

But there is another point of view. Many husbands are able to support their wives and fail to give them anything but a housekeeping allowance, which is often meagre enough for housekeeping alone, and until wives have a recognized status as wage-earning members of the community it is cruel to prevent them not earning a living (they do that), but receiving pay for their work. Even in the lowest class husbands have to have their "bit of spending money." I have known of at least half a dozen cases of wives whose husbands are serving or have served terms of imprisonment rather than support them. It is not likely that medical women would be reduced to such straits, but is any woman going to admit that her husband is not getting on sufficiently well to support her in anything like comfort? Mrs. Patrick Campbell says she had to begin work to get her husband away from city life, for which he was not strong enough. The world could ill afford to lose her in a household drudge. I admit many men would have thought it better that she stayed at home and went out charring! Anything to keep us in the home, gentlemen. But this inquisition about our affairs is intolerable. Next you will be asking us if we are in love, as if so we are ineligible, as love, it is well known, distracts one from work. I hope when the woman appointed to St. Pancras with a dependent husband has got her job he will enjoy his much advertised position. Ye gods! no wonder the independent girl of to-day is so chary of marriage.—I am, etc.,

MARION E. MACKENZIE.

Leeds, May 6th.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 6th the following medical degrees were conferred:

M.B., B.Ch.—G. S. Trower, H. W. Leatham.

UNIVERSITY OF LONDON.

At the Royal Society of Medicine (1, Wimpole Street, W.) three advanced lectures in medicine, as already announced, will be given by professors in the Faculty of Medicine of the University of Paris. Monday, May 22nd, Professor F. Vidal: Subject, Anti-Pain. Tuesday, May 23rd, Professor H. Vaguez: Subject, De l'Erythème (Maladie de Vaguez-Osler), Chairman, Sir Wilmot Herringham. Wednesday, May 31st, Professor J. Babinski: Subject, Des

Reflexes de défense, Chairman, Sir James Purves Stewart. The lectures will be delivered in French, and have been arranged under a scheme for the exchange of lectures in medicine between France and England. Admission is free without ticket.

UNIVERSITY OF ST. ANDREWS.

The Senatus Academicus of the University of St. Andrews has resolved to confer the honorary degree of LL.D. upon Sir Harold J. Stiles, Regius Professor of Clinical Surgery in the University of Edinburgh, and Dr. C. R. Marshall, Professor of Materia Medica in the University of Aberdeen.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary Comitia of the Royal College of Physicians of London was held on May 11th at 5 p.m., the President, Sir Humphry Rolleston, occupying the chair.

The following fourteen members elected to the Fellowship at the previous Comitia were admitted and gave their faith to the College: Dr. Edwin Hyla Greves, Sir Sydney Russell-Wells, Dr. Ewen John Maclean, Dr. Arthur Herbert Hayes, Dr. Robert Alfred Bolam, Dr. William Henry Wynn, Dr. Charles Paget Lapey, Dr. Edward Fretson Skinner, Dr. Owen Lambert Vaughan Simpson, Dr. John George Porter Phillips, Dr. Harold Wordsworth Barber, Dr. Arthur Geoffrey Evans, Dr. Aldo Castellani, Dr. Henry Hallett Dale.

Dr. Raymond Crawford was elected Senior Censor.

A licence to practise physic was granted to Yassa Sudki Soliman, Cairo, and St. Thomas's Hospital. Diplomas in Public Health were granted jointly with the Royal College of Surgeons to the successful candidates.

Communications were received relating to the attendance of Fellows and Members of the College in connexion with the processions in the appeal for the hospitals on Empire Day, and permission was accorded.

The College sent was affixed to a Latin address to the University of Padua on the occasion of its seventh centenary.

A report was received from the Censors Board concerning the alterations of a resolution of the College and certain by-laws. After some discussion it was referred back for further consideration by the Censors Board.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on May 11th, when Sir Anthony Bowlby, President, was in the chair.

Issue of Diplomas.—Diplomas of Membership were granted to 128 candidates found qualified at the r The names were printed in the report of the College of Physicians published on May 6th, of Public Health was granted, jointly with the Royal College of Physicians, to 20 candidates found qualified. The Diploma in Tropical Medicine was granted, jointly with the Royal College of Physicians, to 24 candidates found qualified. (The names were printed in the report of the Comitia of the Royal College of Physicians, published on May 6th, p. 742.)

International Congress of the History of Medicine.—The President reported that he had arranged to receive the members of the Third Congress on Wednesday, July 19th next, from 3 to 5.30 p.m.

The Services.

SURGEON COMMANDER B. H. MORRIS, of the Royal Australian Naval Reserve, has been awarded the Volunteer Officers' Decoration.

CAMPAIGNS IN PERSIA.

The following are among the awards announced in connexion with minor military operations in North and North-East Persia during the period 1917-21:

O.B.E. (Military): Major (acting Lieut.-Colonel) Michael Keane, R.A.M.C.

M.B.E. (Military): Captain Jolal Moolchool Shah, I.M.S., 1st Class Senior Subassistent Surgeon Mirza Muhamed Beg, Khan Bahadur, I.M.D.

To be Brevet Major: Captain (temporary Major) C. H. Harold, R.A.M.C.

The names of the following officers have been brought to the notice of the Secretary of State for War for distinguished services rendered in connexion with the operations: Captain (temporary Major) C. H. Harold, R.A.M.C., Major (acting Lieut.-Colonel) M. Keane, R.A.M.C.

DEATHS IN THE SERVICES.

COLONEL MICHAEL JOHN SEXTON, C.B., LL.D., Army Medical Staff (retired), died at Herne Bay on April 29th, aged 61. He graduated as M.D. and M.Ch. in the Royal University of Ireland in 1883, and entered the army as surgeon in August, 1885. He became full colonel in 1915, and retired in December, 1917. He served in the Burmese war in 1885 (medal with clasp); in the Chin Lushai campaign on the North-East Frontier of India in 1893-99 (clasp); in the South African war in 1901-02, in operations in the Transvaal, the Orange River Colony, and Cape Colony (Queen's medal with three clasps); and in the war of 1914-18 as an A.D.M.S. of the Mediterranean Expeditionary Force, and afterwards as D.D.M.S. of the lines of communication of the Egyptian Expeditionary Force, when he was mentioned in dispatches in the London Gazette of January 23rd, 1916, and July 6th, 1917, and received the C.B. on January 1st, 1916.

Obituary.

SIR HENRY DAVY, K.B.E., C.B., M.D., F.R.C.P.,

Consulting Physician to the Royal Devon and Exeter Hospital;
Ex-President of the British Medical Association.

WE had to announce last week with great regret the death, on May 10th, of Sir Henry Davy, who was President of the British Medical Association when it held its annual meeting in Exeter in 1907. It occurred at his house in Exeter after a short illness, due to cerebral hæmorrhage.

Henry Davy was born in 1855, and was the youngest son of Mr. Henry Davy, solicitor at Ottery St. Mary. From Honiton Grammar School he proceeded to Guy's Hospital, where he became an earnest disciple of Wilks and Moxon, whose teaching had an abiding influence on his outlook of medicine and its practice. He neglected no opportunity afforded by the great school

of which he was a pupil; he took the first prize for first-year students, and while dresser to Mr. Howse he won the Gurney-Hoare prize for an essay on the value of the newly introduced antiseptic, carbolic acid, for the treatment of wounds. This essay was afterwards published in *Guy's Hospital Reports* (1878) under the title "Antiseptic surgery and pyæmia." At Guy's Hospital he held the posts of house-physician and resident obstetric assistant, and was also house-surgeon to the Evelina Hospital for Children and resident clinical assistant at St. Luke's Hospital for the Insane. He was a president of the Students' Physical Society, and frequently spoke in debates on both medical and surgical subjects. He was at one time joint editor of the *Guy's Hospital Gazette*, and, with Dr. G. Mackern, published in the *Lancet* in 1877 a paper on the blood in pernicious anaemia, based on observations of a patient under the care of Dr. Moxon. He took the diploma of M.R.C.S. Eng. in 1877 and graduated M.B. Lond., with honours in medicine, obstetric medicine, and forensic medicine, in 1878. He proceeded to the degree of M.D. in 1882, became

a Member of the Royal College of Physicians in 1880 and a Fellow in 1884. On leaving Guy's Hospital he settled in practice as a physician in Exeter and was soon appointed physician to the Exeter Dispensary, of which institution he was made consulting physician in 1907 and president in 1912. In 1881, on the retirement of Dr. Samuel Budd, he was elected one of the two physicians of the Royal Devon and Exeter Hospital at Exeter, and was assiduous in the discharge of the duties of that office. The rules of the hospital would have required his retirement in 1920, on attaining the age of 65, but when the committee understood that he was willing to serve a little longer his appointment was, with the cordial approval of his colleagues on the medical staff, extended for two years. He, however, preferred to retire in 1921, when he was appointed consulting physician.

For many years he held a leading position in the profession in the West of England. He was of a very practical turn of mind, a shrewd judge of men and theories, who kept himself well informed of the progress of medicine, and took pains, by visits to the hospital at which he had been a student and

in other ways, to make himself acquainted with new methods of diagnosis and treatment. It is no wonder, therefore, that his opinion was often sought in difficult cases, and that he was implicitly trusted by his medical colleagues in all parts of Devonshire; his work was much increased by the self-forgetting readiness with which he responded to any call to attend them, their wives or children, in sickness; he never failed to go to the help of any who needed him. He was staunch and loyal, and his cheery word and pleasant smile gained him many a friend, who did not forget the man when the need for the physician had passed. He was outspoken but of genial disposition, and much given to the virtue of hospitality. His election as sheriff of Exeter in 1887 afforded him special opportunities of displaying it to his numerous personal friends and to the legal and other notabilities of the county; it continued with him to the end.

He had been President of the South-Western Branch of the British Medical Association, and when that Branch invited the Association to hold its annual meeting at Exeter in 1907 Davy was, on its nomination, elected president. In the following year, in connexion with the annual meeting at Sheffield, he received the honorary degree of D.Sc. of the University of that city, and was subsequently appointed one of the vice-presidents of the Association. During his term of office on the Council he took a great interest in its proceedings, and served as a member of the Finance Committee.

The even tenor of Davy's life was interrupted by the war. Under the scheme of territorial hospitals elaborated by Sir Alfred Keogh in 1908 Davy was appointed Lieutenant-Colonel *à la suite* of the 4th Southern Territorial General Hospital, which had its headquarters at Plymouth. Soon after the war broke out, however, he was appointed consulting physician to the Southern Command. He took his duties very seriously and did most valuable and conscientious work. He never spared himself, and for several years almost lived in trains and motor-cars; his services were in constant request in all parts of

SIR HENRY DAVY.

[Ellis and Fry, London.

the command, which included Netley and other large and important hospitals. In spite of the fatigue involved in this constant travelling Davy thoroughly enjoyed his contact with the young and energetic members of the profession serving in the R.A.M.C.; from them he used to say he learned as much and more than he imparted. He was specially interested in the modern methods of studying the manifold forms of cerebral and nerve disturbance, with regard to which his advice was frequently asked. His early interest in antiseptic surgery gave him an added motive for careful observation and comment on modern aseptic methods. He was a member of one of the special commissions that visited the war area in France, and fully appreciated the good work there done, especially all that concerned camp sanitation. His ability and earnestness alike commanded respect, and he received the honours of C.B. in 1917 and that of K.B.E. in 1919.

Sir Henry Davy was twice married; his first wife was the grand-daughter of a well-known Exeter surgeon, Mr. P. C. Delagarde. He had two children, one a son, who was killed

early in the war, the other a daughter, who did most strenuous work with Dame Georgina Buller in organizing and equipping the Devon group of war hospitals. She survives, and has recently taken the LL.B. of the University of London, with a view of being called to the Bar. He married a second time, in 1920, the widow of his old friend Dr. John Mortimer, of Exeter, by whom he is survived.

The funeral took place on May 14th. The service was conducted by the Bishop of Crediton, and in the first part, at the Cathedral, he was assisted by the Archdeacons of Exeter and Totnes. Among the large congregation in the Cathedral were many representative people of the county of Devon and city of Exeter, including the mayor and sheriff of Exeter, the present M.P., Sir Robert Newman, and the past M.P., Sir Henry Duke, and a very large number of members of the medical profession. The British Medical Association was represented by the president of the South-Western Branch and chairman of the Exeter Division, Dr. W. Gordon, who, with Mr. E. J. Douville, consulting surgeon, represented the staff of the Devon and Exeter Hospital. The Association was further represented by Mr. Russell Coombe on behalf of the Council, by the Branch Secretary, Dr. F. A. Roper, and by the Division Secretary, Mr. Norman F. Loek. There were representatives of many public bodies with which Sir Henry Davy had been connected; also a very large number of personal friends were present.

Sir WILLIAM HALE-WHITE has sent us the following appreciation: Davy was my senior as a student at Guy's Hospital, but I saw much of him then and since. Even thus early his industry was manifest. Fortunately he combined with it a great aptitude and affection for his profession. These characteristics never left him. Shortly before his fatal illness I chanced to ask him what he would do when he retired; he replied that he never would retire, for he cared for nothing so much as the practice of medicine. His power of application was immense—holidays were only a dose of tonic to enable him to work harder. The Command in which he served in the war extended from Southampton to Land's End. The energy with which he threw himself into the duties of President of the British Medical Association when it met at Exeter will be remembered gratefully by all who were present, and this occasion brought out his keen enjoyment of being hospitable. Never was he so happy as when entertaining his friends, particularly if they were members of his own profession. He had the well-balanced mind that is appropriate to a physician; if there were insufficient data he was not ashamed to refrain from giving an opinion, but if he committed himself to a diagnosis it was pretty sure to be as good as could be made. He always surveyed the whole surroundings and circumstances of each individual patient, and therefore the advice given was sound and sensible. More than his share of troubles came his way: a severe bicycle accident led to a long illness, another time he damaged himself by a fall on a railway platform, his first wife's health was very bad for many years, he lost his only son in the war; but each trouble was borne bravely and silently without a word of complaint. He had a fellow feeling for others in distress; often has he helped them handsomely, unostentatiously, and secretly. Many were quite unaware when they met him that they were talking to a brave and generous man. As might be expected, with such a character, he was intensely loyal to his profession and his friends. For either he would, without stint, do all that lay in his power, and he will always be to patients, doctors, and friends a memory of ungrudging kindness and help.

Mr. RUSSELL COOMBE writes: When I came to Exeter as house-surgeon Henry Davy, although slightly younger than I, had been some time full physician to the hospital with some thirty beds at his disposal. It did not take me long to realize that I had met one of marked ability and possessed of an unusual familiarity with practical medicine. He indeed already held an outstanding position, and it was to him even then that his colleagues turned for advice and counsel in difficult cases. Not long after the termination of my house-surgeoncy I became one of his colleagues on the staff of the Exeter Dispensary, and discovered with astonishment the size of the out-patient clinic he conducted there. Three to four hours twice a week were given to this service.

This combination of simultaneous in-patient and out-patient experience gave him opportunities which, surely, come but to few physicians, and he made the most of them. I found in

later years that when a difficult case arose he could almost invariably produce notes of a similar case—seen either whilst he was a resident at Guy's or the Evelina, or in the Exeter Hospital or at the Dispensary. It was this systematic note-taking which early gave him the collated experience that men in Exeter and for fifty miles round learned to prize so highly. He seemed often to diagnose intuitively, and yet as soon as discussion arose one found his opinion based on solid experience.

But to his medical brethren Davy was not only the skilled physician. To numbers of them he has been a refuge in times of trouble—repeated long journeys on winter evenings to see the dangerously ill wife of a medical man fifty miles away in North Devon; gifts of things wanting to the wife of another practitioner are instances of goodness of heart that could not be exceeded—yet these acts have only come accidentally to my knowledge. At his funeral I saw a practitioner from thirty miles away who owes his wife's life to an accurate diagnosis of Davy's. . . . made by a great authority. Thus we all, his . . . had got to love him. He mixed with others and entered into their feelings. Thus he developed a knowledge of life and sympathy with all. It was this sympathy that gave the laity such confidence in him as a medical adviser. Moreover, a Devonian by birth and ancestry, with a deep love of his county and knowledge of it from boyhood up, there must have been quite a large number of patients of whom he knew something as soon as he heard their names. He eminently fitted the position he filled.

His war work was excellent, and we were all proud of it. I chanced to be at Netley when the news of his appointment as consulting physician to the Command appeared. The appointment of a provincial physician was, perhaps, not received, shall I say, with enthusiasm, but it was not long before his professional knowledge was fully recognized, and before his geniality and *savoir-faire* rendered him a most popular and trusted officer.

His life evoked much sympathy from us all; the sad and tedious illness of his first wife and his only son's death in the war left him, it seemed to us, a sad and sorrowful man. Thus all who knew him rejoiced in the happiness his second marriage brought him. The tragedy is that two short years have brought this happiness to an end; again our deepest feelings of sympathy are aroused for his widow. The end was, yet, what he would have wished. He often told me he wished to die in harness, and dreaded the time when he could no longer work. The sadness is that it has come so much too soon—too soon for him, since it has cut short what was obviously a period of happy and contented life; too soon for us, since it has taken from us a *compère* who could only be lost with deep sorrow. He was a great physician, a worthy and loving son of Devon, and we are all the poorer for his loss.

ROBERT BRUCE LOW, C.B., M.D. EDIN., D.P.H. CAMB.,
Late Assistant Medical Officer, Local Government Board.

It is with feelings of the deepest regret that we record the death, on May 12th, after a short illness, of the distinguished epidemiologist and sanitarian, Dr. R. Bruce Low. He was in his 77th year, and up to within a week of his death was engaged in literary work of much importance to the public health service.

Robert Bruce Low was born in Edinburgh in 1846 and educated at the Royal High School and University of his native city. After graduation in 1867, he became house-surgeon at the Royal Infirmary, Edinburgh, and then devoted a year to post-graduate study at St. Thomas's Hospital, London, and at the Universities of Würzburg and Berlin. He next practised as a rural general practitioner for nineteen years; the first four were spent in Lincolnshire and the remaining fifteen at Helmsley, in the North Riding of Yorkshire. During the latter period he became medical officer of health for Helmsley Rural District and district medical officer, public vaccinator, and workhouse medical officer to the Board of Guardians of the Helmsley Union, besides being deputy coroner for the North Riding of Yorkshire.

The life of a general medical practitioner in a sparsely populated area was far different in those days from what it is at present. There were then few really good roads in the district, and Bruce Low, when visiting his patients, had to undertake long journeys over the moors on horseback, and during periods of stress he spent much time in the saddle, and often went very short of sleep for several days and nights.

His horsemanship called forth the admiration of his former patients quite as much as his medical proficiency. Short in stature, a light weight, distinguished in appearance, always immaculately dressed, Bruce Low was one of the best examples of the practitioner of the old school. The accent he brought from over the border he never lost, and not only those who came into contact with him but his own personal friends realized that he had only one opinion on any subject, and that was an honest one, and one from which he never wavered. He possessed indomitable pluck and perseverance and a wide sympathy with his fellow man. He had not long been in the district before he won the hearts of rich and poor alike by his skill, his steadfast devotion to duty, his kindly personality, the catholic charity which characterized all his actions, and the fact that he was always ready to turn out at any time of the day or night, whatever the weather conditions might be, to alleviate the sufferings of the poorest member of the community. When he entered a house he was greeted not merely as "the doctor" but as a friend of the family who knew and could be trusted with all the secrets jealously guarded from everyone else. So great was their faith in his wisdom and judgement that in all matters of difficulty they appealed to him for help. If, for example, a husband and wife commenced squabbling and would not be reconciled, the remedy at once suggested by friends and neighbours was, "Send for Mr. Low."

Despite the cares and responsibilities of general practice, Bruce Low found time to take a prominent part in the Volunteer movement and subsequently became Surgeon-Major to the 2nd Volunteer Battalion, Yorkshire Regiment. Gradually the importance of preventive medicine, then in its infancy, became impressed upon his mind as a result of his observation of the part played by environmental conditions on the health of the people. His interest in this aspect of medicine was stimulated by occasional conversations with his friend, William Henry Power, at that time a Medical Inspector and later the Medical Officer of the Local Government Board, who used to visit Bruce Low from time to time for the purpose of inspecting his work as Public Vaccinator. In the evening the two of them would sit and smoke and discuss problems relating to epidemiology until the early hours of the following morning.

In 1879 Bruce Low took the D.P.H. of Cambridge University, and during his tenure of office as M.O.H. of Helmsley Rural District did much to promote the public health of the area, not merely by effecting improvement in the sanitary circumstances of the district, but also by impressing upon the people the necessity of observing the laws of healthy living. These efforts to introduce sanitary reforms were at first bitterly opposed by certain local persons of influence, but his earnestness of purpose and determination prevailed, and those who had at first done everything to obstruct became in the end his staunchest supporters. His experience caused him to publish in 1886 an article on the tenure of office and appointment of medical officers of health, in which he showed the necessity to secure for these officers better terms of appointment and protection against arbitrary treatment by sanitary authorities. In after-life it was the memory of his early struggles in the cause of hygienic efficiency that made Bruce Low the sympathetic and understanding friend of all part-time medical officers of health.

As a result of the favourable impression which the Central Health Authority had formed of Bruce Low's public work in Helmsley, and of his recognized ability as a medical practitioner of high standing, he was invited, in 1887, to become a medical inspector of the Local Government Board; he readily accepted, despite the fact that he incurred thereby substantial pecuniary loss in exchanging a remunerative practice for the paltry salary offered by a Government department. Before leaving Helmsley he was entertained to a farewell dinner, presided over by the Earl of Feversham, at which all the leading men of the district were present. At this dinner many speakers testified to the usefulness of the work he had performed, and to the esteem and affection in which he was held by all. Bruce Low commenced his new duties with characteristic enthusiasm and energy. He had the advantage of being brought into intimate association with the three great exponents of the science of hygiene in its broadest aspects—namely, Buchanan, Thorne Thorne, and Power—who as successors to John Simon, the founder, were engaged in building up the fabric of the English public health service. Under their direction he had daily opportunity of studying the many and ever-varying problems

relating to epidemiology and public health administration. The personal influence of his early colleagues was reflected in all his subsequent work, and he was ever anxious to acknowledge his indebtedness to them. His published reports to the Local Government Board cover a wide range of subjects and relate to the sanitary circumstances and administration of many districts, and to outbreaks of small-pox, diphtheria, diarrhoea, enteric fever, influenza, pneumonia, cerebro-spinal fever, cholera and plague, and suspected plague, in England and Wales. Probably the best known of his reports relating to water supplies are those on the river Trent area of Lincolnshire and Nottinghamshire (1893), and the pollution by sewage of the river Dee (1896). In 1904 he wrote on the arrangements in Germany for the isolation of small-pox, and in 1905 on the state vaccine establishments of that country.

It was, however, through his writings on epidemiology that his name became known throughout the world, and that he was brought into close association with members of the medical profession in many countries. He wrote a series of reports, carried on over a succession of years, on the progress and diffusion throughout the world of plague, cholera, yellow fever, and the epidemiology in recent years of typhus fever (1915), acute anterior poliomyelitis (1916), and small-pox (1918). The study of disease distribution throughout the world led Bruce Low to acquire a comprehensive knowledge of port sanitary administration, and in reply to an inquiry he furnished the Rockefeller Institute with a short historical statement showing the steps which led up to the abandonment of quarantine in the United Kingdom. This was published later in the annual report of the medical officer of the Local Government Board, 1917-18.

Bruce Low was Examiner in Sanitary Science, State Medicine, and Public Health at the Universities of Edinburgh, Glasgow, Leeds, and Cambridge. The confidence placed in his judgement and fairness was illustrated by his being, for practical purposes, the sole examiner in Part II of the D.P.H. examination at the last-named University during several years of the war period. After he had ceased to be an examiner in 1919, he was appointed by the General Medical Council as Inspector of Examinations to visit the examinations of the twenty-two examining bodies that grant degrees and diplomas in public health and sanitary science in the United Kingdom and Ireland, with the object of ascertaining whether need of improvement existed in the course of study and standard of knowledge required of candidates, and to formulate a comprehensive scheme to secure for each of the various examinations a common standard of proficiency. This duty occupied the best part of the last two years, and his comprehensive and valuable report is now under the consideration of the General Medical Council.

Bruce Low served on the War Office Antityphoid Inoculation Committee from 1904 to 1912. He was a member of the Council of the Epidemiological Section of the Royal Society of Medicine and a Fellow of the Society of Tropical Medicine. He was promoted to be an Assistant Medical Officer of the Local Government Board in 1900, and in 1911 he was retired from the public service, having reached the age limit. His retirement was of short duration, for, owing to the death of one and the serious illness of another of his colleagues, he was recalled to duty for a short period in the same year and again in the following year, while in September, 1914, he rejoined the staff for war work, and was only finally retired in May 1921.

He was willing at all times to assist and advise members of the profession and other interested persons in matters relating to public health, and this earned for him the respect and esteem of many. To his colleagues of all grades he was a constant and true friend; it is probable that he was never happier than when assisting, instructing, and advising them in their work and when placing his wide knowledge and experience at their disposal; in their turn they valued and appreciated his kindly teaching and counsel, and all cherished towards him a deep and affectionate regard. He was proud of being a civil servant, and in his life and by his work he personified the highest ideal of the old Civil Service. His long and distinguished career in the service of his country and to public health medicine was recognized in 1919 by his appointment to be C.B.

AN OLD FRIEND writes: Of Dr. Bruce Low it might on two grounds be said, *Felix opportunitate moritis*. The time for his retirement from the Civil Service came before the war, but war exigencies led to his being asked to continue

his work at Whitohall. He complied, greatly to the public benefit, and only quite lately did it become practicable to relieve him. Also it happened that only a year or so ago the General Medical Council required as inspector of the D.P.H. examinations throughout the United Kingdom a public health expert whose authority and impartiality would be universally admitted. This man they found in Dr. Bruce Low. His courtesy and tact in reporting on the various examinations left the bodies with hardly a remark to make in reply, but when it came to the issue of his general report, and to his proposals for revision of the whole D.P.H. curriculum, it at once appeared that with all his suavity he had been wide awake throughout. The report will have a far-reaching influence on the future teaching of preventive medicine. It was his last bit of public work, and having completed it he departed, at a ripe old age, without any prolonged suffering or illness.

HENRY GEORGE FELKIN, M.D.LOND., D.P.H.

DR. H. G. FELKIN, so well known as one of the heads of Linford Sanatorium in the New Forest, died after a few days' illness on May 8th, just before reaching his 54th birthday.

Henry George Felkin was educated in Germany, where his father resided, and at the Wolverhampton Grammar School. After a year at St. Bartholomew's spent in the study of the preliminary scientific subjects he migrated to the London Hospital, where he completed his medical education and served as house-surgeon. At the M.B. (Lond. Univ.) of 1893 he gained honours in medicine; he took the M.D. in 1896 and the D.P.H. (R.C.P.S.) in 1899.

Dr. Felkin's long connexion with the treatment of tuberculosis began with his appointment as house-physician at the Brompton Hospital; afterwards he became resident medical officer, and it was in those years he laid the foundation of the profound clinical knowledge of pulmonary tuberculosis and its treatment which characterized his after-career. In 1901 he joined Dr. R. Mander Smyth in partnership at the Linford Sanatorium, and for the rest of his life his best was given to the welfare of the place and its patients. He was rewarded by the confidence, gratitude, and affection of generations of patients to a degree which few men have ever won. The secret of his success in the career he chose lay, in the opinion of the writer, who knew him well, partly in his great natural clinical ability, partly in a remarkable patience and persistence which never lost heart, and was slow to acknowledge defeat, even in unpromising cases, and largely in the fact that beneath a blunt exterior lay a most sympathetic nature which his patients all came to recognize. Dr. Felkin knew pulmonary tuberculosis "from A to Z," and his patience never wearied in studying the special symptoms of those under his care. A rare combination of qualities is needed for success in sanatorium treatment, where the physician lives in such close daily contact with his patients, and this Dr. Felkin possessed in full degree. He was able to treat, to inspire, to control, and so to cure.

Dr. Felkin's interests in life were not bounded by his professional work. He was always a lover of literature, and after he settled in the New Forest he developed a love of nature and of sport which had previously been hidden even from his friends. He was cut off in the midst of the development of plans for the extension of the scientific side of his work, and leaves a gap which it will be very hard to fill. In 1905 he married Miss Elizabeth Ann Malton, who survives him.

We regret to record the death on May 1st, at the age of 64, after a long and painful illness, of Dr. GEORGE DUNN WILSON, of Clapham. Dr. Wilson was born in Cork and received his medical education at Queen's College, Cork, at Edinburgh, and at the London Hospital. He had been in practice in Clapham for upwards of thirty years, and was held in high esteem by his patients and his colleagues. He was surgeon to Clapham Benevolent Dispensary, and was a Justice of the Peace for the County of London. He was a former Chairman of the Wandsworth Division of the British Medical Association, and he was also a strong supporter of the National Medical Union, of which he was vice-president. Dr. Wilson was keenly interested in politics and was chairman of the Clapham Constitutional Club, a post which he filled for many years, and vice-chairman of the Clapham Conservative Association.

DR. JOHN HOWELL KNIGHT GRIFFITHS died on April 25th of pneumonia, at the age of 52, at his residence in Fulham Road, S.W. He was a native of Kidwelly, South Wales, and was educated at Carmarthen Grammar School and the University College of Wales, Aberystwith. He proceeded for his medical studies to the University of Edinburgh, where he graduated M.B., C.M. in 1895, taking the M.D. degree in 1897. He was appointed house-surgeon to the Carmarthenshire Infirmary in 1896, and in the following year he settled down in practice in Fulham. He built up a large and successful general practice in the neighbourhood, where he remained to the day of his death. During his twenty-five years in Fulham he was remarkable for his devotion to his patients, his very genial and sympathetic manner, and his optimistic view of life. He was popular not only among his patients but also with his fellow practitioners. He leaves a widow, two sons, and two daughters. He was an old member of the British Medical Association.

THE death took place at Culross, Fife, on May 11th, of Dr. ROBERT MACLAREN WISHART, of Edinburgh, in his 40th year. Dr. Wishart was educated at Edinburgh University and School of Medicine, and qualified in 1903 with the diplomas of L.R.C.P. and L.R.C.S. Edin.; subsequently he obtained the D.P.H. (Dubl.) in 1912, and graduated M.B., Ch.B. Edin. in 1916. In 1914-15 he served as a civil surgeon in the Edinburgh and Border Hospital at Dunkirk, and later he joined the R.A.M.C., holding the rank of temporary captain. He was a Fellow of the Edinburgh Obstetrical Society and of the Zoological Society of Scotland, and he was physician to the Boys' Industrial Brigade Home.

Medical News.

SIR RICHARD GREGORY, F.R.A.S., the editor of *Nature*, has been elected President of the Decimal Association in succession to the late Lord Belhaven and Stenton.

A CHADWICK public lecture will be given in the Chelsea Physic Garden on Thursday, May 25th, at 5 p.m., on "Superstitions of early herbalists," by Mr. Augustus Bowles, M.A., F.L.S. The chairman will be Sir William Collins, K.C.V.O., M.D. Admission is free.

DR. DAVID J. SCOTT, O.B.E., M.C., of Gray's Inn, has been called to the Bar.

THE annual dinner of the West London Medico-Chirurgical Society will be held at Princes' Restaurant, Piccadilly, on Wednesday, June 7th, at 7 for 7.30 p.m.

THE War Office announces that the War Office Committee of Inquiry into Shell Shock held its fortieth meeting on May 10th, Lord Southborough presiding. The Committee has finished taking evidence and has had the benefit of the experience of a large number of experts, both military and medical. It is now considering its report. The report will deal in detail with the origin and nature of shell shock, and will suggest measures which may be expected to mitigate the incidence of this group of nervous and mental disorders in future wars, and also measures for the treatment of patients suffering from such disabilities.

A MEETING of the Tuberculosis Society will be held at the Margaret Street Hospital, W.1, on Monday, May 22nd, at 7.30 p.m., to discuss the therapeutics of tuberculosis as carried out in a tuberculosis dispensary.

MR. J. S. MCARDLE, F.R.C.S.I., of Dublin, was recently entertained to dinner by his professional colleagues and others, who presented to him a number of valuable gifts. Dr. M. F. Cox, who presided, in proposing the toast of the guest of the evening, said that Mr. McArdle had by his genius and his capacity for work made for himself a position unparalleled in surgery in Ireland. He had given loyal service to St. Vincent's Hospital, to his country, to his patients, and to the National University. The presentations included a portrait of Mr. McArdle by Dr. Boyd Barrett, himself a former student of St. Vincent's Hospital; a motor car to Mrs. McArdle; a surgical prize in perpetuity of £20 to the best surgical student of each year in St. Vincent's Hospital, to be known as the "Surgeon McArdle Prize"; and a gold medal in surgery, to be known as the "Surgeon McArdle Gold Medal" in University College, Dublin.

PLAGUE appears to be prevalent in Java to a serious extent. We have seen no record of the number of cases, but there were 1,595 deaths from the disease in February, and 1,546 in March.

THE Lord Mayor of London will preside at the Annual Meeting of the People's League of Health at the Mansion House on Thursday, May 25th, at 3.30 p.m. The speakers will include Sir Bruce Bruce-Porter, Dr. Farquhar Buzzard, Miss Olga Nethersole, and Dr. Saleeby.

THE summer meeting of the Medical Golf Society will be held on Thursday, June 8th, at Stoke Poges Golf Club. Any gentleman on the *Medical Register* wishing to play can become a member of the society, without election, by forwarding the annual subscription of 10s. to the honorary secretary; there will be no further entrance fee for the meeting. The *Lancet* Challenge Cup will be presented for the best scratch return r. Bogey; and the "Henry Morris" Challenge Cup and the Society's gold medal will be presented for the best return under handicap, in either class. Class I includes members with handicaps of nine and under, and Class II those with over nine, the handicap being eighteen. Intending competitors may obtain particulars from Dr. Rolf Creasy, junr., 36, Weymouth Street, W.1.

THE Chelsea Hospital for Women has received from its chairman, Sir Frederick Eley, Bt., a donation of £1,000.

A COMPLIMENTARY dinner was given and valuable presentations made on May 1st to Dr. J. A. Ward on his retirement and departure from Grays, Essex. Dr. Ward had been in practice at Grays for twenty-seven years, and was medical officer of health for over twenty-two years. Reference was made by several speakers to his high reputation in the district and to his popularity among his medical colleagues and patients.

THE annual meeting of the Canadian Medical Association will be held at Winnipeg from June 20th to 23rd inclusive. Dr. L. F. Barker of Baltimore is to give the address in medicine, and Dr. J. M. T. Finney, also of Baltimore, has been asked to give the address in surgery. The scientific work of the meeting will be carried on in a surgical section, a medical section, an eye, ear, nose, and throat section, and a general section; and, instead of a formal pathological section, a series of pathological demonstrations will be given. The Canadian Society of Anaesthetists and the Canadian Radiological Society will also hold their annual meetings in Winnipeg at the same time.

IN Berlin there were, in 1920, 164 antivenereal disease dispensaries; 86,456 persons applied for treatment and 184,511 consultations were given, an increase of 80 per cent. on the previous year.

PROFESSOR MAYER, who has recently held the chair of physiology in the Strashourg Faculty of Medicine, has been appointed successor to the late François Franck at the Collège de France.

THE Royal Society gave the first of its two annual conversations on the evening of May 17th at Burlington House. The President, Sir Charles Sherrington, G.B.E., M.D., received the guests, who were then free to study the exhibits displayed in the library and other rooms of the society. On the physical side these included models of crystal structure as determined by x-ray analysis, shown by Sir William Bragg and Professor W. L. Bragg; an instrument for measuring the percentage of carbon dioxide in alveolar air, made by the Cambridge and Paul Instrument Company, Ltd., at the suggestion of Professor A. V. Hill; and specimens of smoke, fog, and volcanic dust particles from the air, together with the instrument for making the records; shown by the Advisory Committee on Atmospheric Pollution. Among the biological exhibits was a collection of models and drawings to demonstrate the brain and brain-ase and the poise of the head in primitive members of the human family, shown by Professors Elliot Smith and John I. Hunter. One series of these models showed the occipital regions of eight endocranial casts (from that of a gorilla to that of Dean Swift), illustrating the progressive expansion of the brain; another series showed the straightening of the axis of the brain in the course of evolution; a reconstruction of the Pittdown skull indicated its original owner as a very lovely member of the human family. Dr. L. Hogben and Mr. F. R. Winton showed slides illustrating the specific effect of injecting pituitary extract (posterior lobe) upon frog melanophores; under its action the pigment cells expand; the method should be of value in the standardization of pituitary extract. Interesting and suggestive methods of measuring the bactericidal potency of the blood fluids and leucocytes were exhibited by Sir Almroth Wright; and Dr. Alexander Fleming demonstrated the most lysozymic action of tissues and secretions, perhaps the most remarkable being that of tears in large dilution. Major F. W. Crags, I.M.S., showed preparations illustrating the course of the spermatozoon in the female bed-bug. An unusual exhibit was the original portrait of Galileo by Justus Sustermans, which has special interest in this the 700th anniversary year of the University of Padua, at which Galileo was Professor of Mathematics for sixteen years.

A GENERAL meeting of the National Health Society, which is now in its fiftieth year, was held at the house of the Royal Society of Medicine on May 10th, when H.R.H. Princess Christian, the President, presented certificates to successful candidates in the examination for health workers which the society has instituted. The Duke of Devonshire, President of the society's council, took the chair, and in the absence of Sir James Crichton-Browne an address was delivered to the candidates and students by Professor H. R. Kenwood, who explained the value of the health visitor and the character of her work in this country and abroad. Dr. Shadick Higgins, M.O.H. St. Pancras, emphasized the importance of women's work in public health, and attributed the great reduction in infant mortality observed in recent years largely to the activities of the health visitor. Sir Adrian Pollock, Chamberlain of the City of London, spoke of the Nurses' Loan Fund organized by the society, and expressed the society's thanks for grants made from the Central Committee on Women's Training and Employment and from the Red Cross and the Royal Medical Benevolent Fund in some special cases; also for the assistance given by various benevolent institutions to educated women anxious to qualify as health visitors under the Board of Education and the Ministry of Health. He mentioned the hostels organized and started by Her Royal Highness for the benefit of working women in London, which had been very helpful to the lady students whilst training. Votes of thanks to the Princess, the Duke of Devonshire, and the Royal Society of Medicine were passed at the instance of Dr. Charles Porter, M.O.H. Marylebone, Bishop Ridgeway, and Sir E. Ray Lankester respectively.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

ACTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Ailology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin); telephone, 4737, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

TREATMENT OF CRAMP.

DR. E. HUGHES (Liverpool) writes: In reply to "M.D.Edin.," very small doses of sulphate or acetate of copper will probably be efficacious, gr. 1/50 to 1/25, or die.

DR. DOUGLAS L. THOMSON (Newbury) writes: If "M.D.Edin." will try 10 grains antipyrin at night I think he will find that it will cure the cramp in the legs. I had a patient who suffered similarly, but after the first dose of antipyrin there was no recurrence of cramp.

"A RETIRED M.D.CANTAB." writes: I have been for many years a sufferer from cramp, chiefly in the night, and sometimes so intense as to cause syncope. It is associated with a tendency to mild arthritic and neuritic troubles, and with intestinal spasm; yet in spite of these I retain the sense of health of body and mind. The cause of the cramp seems to be a toxin generated in the intestine—possibly lactic acid, for the cramp is enormously intensified by the ingestion of cheese made with the lactic acid bacillus; it is also intensified to a less degree by milk and by excess of starch or an insufficient ratio of protein to starch. Phenacetin acts as a prophylactic, and sodium carbonate in large doses (5j or 5ij) gives temporary relief. But these drugs cannot be taken regularly without injury to health; so the best treatment is to restrict the amount of starch and of milk as far as possible, to take plenty of animal food, and of uncooked fruit as possible, to take the sake of salts and accessory foodstuffs. Sugar in moderation seemed less injurious than starch, probably because it is more quickly absorbed, and therefore not so liable

to fermentation. If the colon cannot be kept clean otherwise, enomata may be used; but aperients favour fermentation by keeping the intestinal contents too watery.

BOTTLES ON MOTOR CYCLES.

DR. MICHAEL W. KELLY (Killaune, Enniscorthy, co. Wexford) writes: I should be much obliged to any motor-cycling members for hints as to carrying bottles and other breakable articles in a midwifery bag on a motor cycle.

TINNITUS AURIUM.

"T." asks for advice in the treatment of a patient who for three years has suffered from persistent tinnitus in the left ear; six months ago it commenced in the right ear. He has been in the tropics for the past twenty years and takes quinine regularly; when quinine was stopped for six months at home the condition did not improve. His hearing is good. All the usual remedies have been tried without avail.

STAINS FOR BLOOD FILMS.

DR. J. SHULMAN (House-Physician, Coventry and Warwickshire Hospital, Coventry) writes: Of late I have been making a number of blood examinations, and the Jenner and Leishman stains which I have had at hand have given very disappointing results, especially with the white cells. I have found that staining with haemalum and eosin in the ordinary way gives excellent results, and as I have not seen it mentioned in any textbook I have referred to, I should like to hear of any objections to this method of staining blood films.

INCOME TAX.

"ARDUUS" has for twenty years paid income tax on the basis of his receipts for the previous calendar year. He has received an additional demand for 1918 which, as he is informed, arises through an increase of £500 in his income from investments.

"* We do not see why an increase in investment income should be taken to require an increase in the assessment on earnings, which rests on entirely different facts. In 1918 an increase of £500 in taxed income would involve payment of tax on earnings at a higher rate. As the law stands, professional profits are assessable on the three years' average, and income taxed at the source forms part of the total income of the recipient, according to the basis of the current year. The society to which "Arduus" refers in the course of his letter is probably the Income Tax Payers Protection Association, 69, Fleet Street, E.C.4.

"D. J. D." qualified in January, 1920, and became an assistant in April, 1920; he asks as to the basis for computing his income tax returns.

"* The three years' average cannot be applied to include years when a person is not carrying on the business or vocation. For the year to April, 1921, he is chargeable on the amount of his earnings for that year; for 1921-22 on the same amount; for 1922-23 on the average of the earnings of the first two years, and thenceforward on the average of three years' earnings—that is, assuming that "D. J. D." remains an assistant. The expense of hospital and examination fees necessary to take higher qualifications cannot be deducted for tax purposes.

"A.M.D." has been appointed as assistant M.O.H. to take an appointment in another locality. He asks if he can deduct removal and temporary accommodation expenses.

"* No; such expenses cannot be regarded as incurred wholly, exclusively, and necessarily in the performance of his new duties.

"E.Y." purchased a car in 1914 for £145 and sold it in 1918 for £80. In 1922 he purchased a car for £400. He asks what he can claim.

"* The amount allowable to "E.Y." is the 1922 cost of a car of similar power, condition, etc., to the one purchased in 1914, less the £80 obtained by the sale of his old car; the amount expended over and above that excess represents capital outlay on improvements.

"T. A. B." has retired from colonial practice and resides in this country about four months a year. His income is derived entirely from Colonial Government securities.

"* He is liable to income tax on income derived from this country from literary or other work, and in our opinion service on a ship working from an English port would not count as residence in this country provided that no residence was retained here to which he could return, in which case such income would count as foreign income.

"H." asks: Should remuneration under the Insurance Act be declared as part of the income from private practice?

"* It is clear that in the great majority of cases it is much more convenient to include all the professional earnings in one general amount. The authorities concur in the practice, which, in our opinion, has sufficient legal justification.

"G. H. J." inquires as to the allowance to be made for the replacement of a Hupmobile car plus Douglas motor cycle by a Riley car plus an Overland car.

"* It is assumed that the Hupmobile and Douglas were purchased new and not in second-hand condition. The allowance due is the cost of a Hupmobile car plus Douglas motor cycle at the date the replacement was effected, less £185, which our correspondent states was the sum obtained for the old car and cycle.

LETTERS, NOTES, ETC.

MOROCCO BOUND.

DR. LEONARD WILLIAMS writes: May I crave a space in your columns for an announcement which reaches me from my friend Dr. Gardette, editor of *La Presse Thermale et Climatologique*, concerning two voyages for medical men which he is organizing to the Moroccan coasts for the late autumn? The first starts from Bordeaux on September 20th, and returns to Marseilles on October 22nd. The second starts from Marseilles on October 19th, and returns to Bordeaux on November 23rd. The accommodation both in transport and sojourn will be what is known as first class, and there will be no tips. The price for a medical man is 4,750 francs (about £95), and for an accompanying wife or daughter 4,950 francs (about £100). Any further details may be obtained from Dr. Gardette, 3, Rue Humboldt, Paris—not from me, please.

THE TREATMENT OF PNEUMONIA.

MR. VALLABHDAS N. MEHTA (Viramgam, Bombay Presidency) writes with reference to an article in the BRITISH MEDICAL JOURNAL of March 11th (p. 420) on the treatment of pneumonia: During the last influenza epidemic, and subsequently in numerous cases of lobar pneumonia, I have used Dr. Arthur J. Mathison's specific treatment of pneumonia, and have met with very excellent results therefrom. This combined treatment with creosote and iodide, if commenced from the very beginning, acts as a reliable specific for this dreadful disease, and proves entirely successful. In cases which are lobular, or complicated with meningitis or typhoid, its action is doubtful. This treatment is further diagnostic of some other complication if the symptoms and pneumonic process do not show any signs of abatement after three days. In such cases some other treatment appropriate to the mixed infection, side by side with the specific treatment, as long as the process continues, helps a great deal in shortening the course of the disease.

MOTOR TAXATION.

"F.R.C.S." writes: I read the paragraph on motor-car taxation in last week's JOURNAL (p. 772) with mixed, but mainly depressed, feelings. An equitable arrangement of motor-car taxation seems very difficult to achieve, but I wish to suggest that the fairest method would be one based on the value of the car. In my own case I am the owner (and incidentally the driver) of a Ford—the list price of the new model, complete, is £185, and the tax payable annually is £23. Three neighbouring practitioners have new models of Rovers and Humber—list price £550 (incidentally they have chauffeurs); their motor taxes are about £12 annually and their incomes well into four figures. Without wishing to break any of the Ten Commandments, I feel that either I am being taxed too highly or that they are escaping too lightly. A fuel tax would be relatively hard on us all, but even then I should come off rather badly. I am afraid owners of Fords or Chevrolets will not be content to adopt the *laissez-faire* attitude suggested by Mr. Massae Buist in the concluding part of the article.

INTESTINAL DISINFECTION.

In the note published in the JOURNAL, No. 3194, p. 462, "tabloids" read "tablets."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 30, 31, and 32.

THE appointment of certifying factory surgeon at Kilbirnie (Ayr) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so made.

Advertisements should be delivered, addressed to the Manager, not later than the first post on Tuesday morning, and, if not paid for at the time, should be accompanied by the enclosed cheque.

NOTE.—It is assumed the rules of the Post Office to receive post restante letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

475. **Human Actinomycosis.**
 MATTSON (*Surg., Gyn., and Obstet.*, April, 1922) points out that the organism of actinomycosis does not exist as a normal inhabitant of the oral cavity and gastro-intestinal tract. No case has ever been reported of post-operative infection by this organism, and the source of infection must be outside the body from grain and grasses, where it becomes capable of infecting man and lower animals. For infection to take place there must be an abrasion of the tissues, and the fungus must be brought into contact with this abrasion. He shows that animal to man infection is fairly common; the portal of entry may be the oral cavity, the gastro-intestinal tract, the respiratory system, or through skin abrasions. Metastases do not take place through the lymphatic system, and ulceration is seldom seen unless surgery has been attempted. Secondary infection occurs after operation, the discharge being sero-purulent with the characteristic sulphur bodies, these being the fungus. The jaw cases often start with toothache; a painless swelling may be found in the neck and is taken for an enlarged gland; trismus is common in jaw cases, and psoas spasm is found in appendiceal cases. Appendix cases differ in no way from simple appendicitis; operation is carried out, an abscess forms later and fills the whole right lower quadrant with an inflammatory mass; the mortality in this type is 100 per cent. In lung cases an erroneous diagnosis of tubercle is usually made, and the result is generally fatal. In regard to treatment, potassium iodide is specific, but heroic doses are necessary, moderate doses producing no results; surgery is of value only where the involved tissue can be excised. Radium and x rays are of use as adjuncts to the above.

476. **Abdominal Colic with Porphyrinuria.**
 SNAPPER (*Klinische Wochenschrift*, March 18th, 1922) describes three cases of a peculiar affection which has been named "colica porphyriurica." These cases are characterized by (1) attacks of severe abdominal and lumbar pain, with vomiting and constipation; (2) excretion during the attack of dark red urine containing much haematoporphyrin; (3) a fatal termination with paralytic symptoms in about half of the cases, after several attacks of the colic have occurred. In the first case recorded by Snapper the patient suffered from severe attacks of pain with marked haematoporphyrinuria (detected by spectroscopic examination). The urinary changes persisted in a slight degree when the pain ceased, and continued for some months. After a number of attacks of colic paralytic symptoms appeared, and death occurred. The second case also terminated fatally with paralytic symptoms (regarded as polyn neuritis), and degenerative changes were found in the peripheral nerves. In each of these cases the clinical history and the pathological examination failed to indicate clearly the exact nature of the paralytic symptoms; also the pathological examination failed to reveal the cause of the colic. The third case was not fatal. Very often these cases are not diagnosed correctly. Usually the severe colic with dark red urine is regarded as due to renal calculus. The spectroscopic examination of the urine decides the diagnosis. The prognosis is uncertain, hence the practical importance of diagnosis. Though the patient may feel quite well between the attacks there is the risk of recurrence, complicated eventually with fatal polyn neuritis.

477. **Malaria.**
 COMESSATTI (*Il Morgagni*, January 31st, 1922) in a lengthy article records his experiences with a large number of cases of malaria. He says the disease has been more serious of late years, not only amongst the soldiers but in the civil population. In malarial enlargement of the spleen the movement duo to respiration is often much limited by the presence of perisplenic adhesions. The absence of any enlargement of the spleen in malaria is uncommon, and some perisplenicitis is usually present. Malarial perilepatitis is comparatively rare, although the large liver of malaria is not infrequent. There is no constant relation between the severity of the infection and the size of the spleen. Many varied diseases may be superimposed on the malarial state. The reciprocal effect of typhoid on malaria is of special interest; usually it renders the malaria latent, but neither disease gives immunity from the other. Lobar pneumonia did not appear to be modified by the presence of malaria. The statement that malaria tends to render tuberculosis milder

must be accepted with much reserve. When haemoptysis occurs in malaria, pulmonary disease (tuberculous or cardiac) should be excluded before the haemorrhage is attributed to malaria. Malarial anaemia assumes peculiar gravity in pregnancy. The pigmentary changes in the skin and pathological findings show that the suprarenals are often affected. The author discusses malaria and pregnancy, congenital malaria, malaria and the nervous system (six severe cases with meningitis are reported in full), and the treatment by quinine, by diet, by arsenobenzol, and by radiotherapy, and ends his paper by giving certain criteria to judge whether the malaria is cured or not.

478. **Prognosis of Epidemic Encephalitis.**
 SANZ (*Arch. de med., cir., y espec.*, February 11th, 1922) states that the mortality of epidemic encephalitis varies with the time and place in which the disease has been studied. According to Banis it ranges from 25 to 31 per cent.; in Spain, however, it is approximately only 10 per cent.; according to Tilner and Howe it was 25 per cent. among their 20 cases. Chalier, on the other hand, estimated it as high as 40 or even 50 per cent., and attached an unfavourable significance to the progressive evolution of myoclonic movements. The mortality in Sanz's cases was 17.64 per cent. All these figures refer to the acute stage of the disease. In the chronic stage the danger to life is less, but the prognosis is unfavourable, owing to the persistence of symptoms which interfere with the motor activity of the patient. Moreover, there is always the possibility of the recurrence of the principal symptoms, though this is a fairly uncommon event. The motor sequelae tend to subside slowly with alternate recrudescences and remissions, but in some cases persist indefinitely and defy all methods of treatment. In addition to the Parkinsonian syndrome, which is the most frequent sequel and one of the most refractory to treatment, Sanz mentions a cerebellar form of disseminated sclerosis and a chronic serous meningitis as sequelae of epidemic encephalitis. Finally, as an aggravating factor in the remote prognosis of epidemic encephalitis, there should be mentioned the state of depression into which the patients fall owing to the apparent hopelessness of their condition, with the result that some of them show a tendency to suicide.

479. **The Influence of Underfeeding on Graves's Disease and Diabetes.**
 UNDER the heading "Underfeeding and internal secretion" TALQVIST (*Finska Läkarsällskapets Handlingar*, January and February, 1922) gives a statistical survey of the frequency of diabetes, Graves's disease, and achylia gastrica before, during, and after the war. His clinical material consists of over 13,000 cases of all complaints, and the chart showing the incidence of diabetes and Graves's disease in the period 1912-21 also shows the average weights of all his cases from year to year. During 1918 and 1919 the shortage of food in Finland induced an average decline of weight by about 18 per cent. As his chart shows, there was a remarkable conformity in the decline in weight and in the frequency of the above-mentioned diseases. By 1921 the curves for both diseases showed a marked rise, coinciding with the return to normal of food conditions. The author considers that what he calls the "decimating" influence of underfeeding on these two diseases does not contradict the view that constitutional predisposition plays an important etiological part; but it would seem that involuntary underfeeding does, to a certain extent, prevent the development of both diabetes and Graves's disease in persons predisposed thereto. The curve for gastric achylia was less instructive, but the author is inclined to think that not only Graves's disease and diabetes but also heart disease, abnormally high blood pressure, arteriosclerosis, arthritis, and possibly also nephritis, are conditions which depend largely on an unrationed dietary.

480. **Gold Salts in the Treatment of Tuberculosis.**
 SCHELLENBERG (*Deut. med. Woch.*, April 14th, 1922) enters a caveat against the craze, popular in Germany at the present time, for giving intravenous injections of gold salts in tuberculosis. He has given one of these preparations—krysolgan—to about 80 patients, and with very disappointing results. He discusses seriatim the various beneficial effects claimed for this treatment, such as disappearance of cough and fever, and improvement in the physical signs. But whether he has treated pulmonary tuberculosis or surgical tuberculosis and lupus, the results have been disappointing. As the drug is apt to provoke severe reactions, its administration requires

close supervision, and the suggestion recently made that the drug should be given in ambulant practice is, in his opinion, very ill advised. In addition to his general indictment of krysolgan treatment, the author takes severely to task a Dr. Levy, whose recent publication contained most extravagant claims.

481. Ligation of the Limbs for the Pulmonary Oedema of Acute Nephritis.

EHRENBERG (*Deut. med. Woch.*, April 7th, 1922) has in two cases of severe pulmonary oedema, due to acute nephritis, obtained marked relief by constricting all four limbs with rubber tourniquets. This device was recommended in 1910 and 1911 by Tabora and Tornai on the assumption that, by cutting off a considerable quantity of the blood from the general circulation, the right heart would be relieved. In the first case recorded by the author this procedure was followed in a couple of minutes by the cessation of a distressing cough and by diminution of dyspnoea. After ten minutes the attack had completely passed off, and during the remaining weeks of the patient's life there was no recurrence of sudden pulmonary oedema. In the second case these attacks were frequent, but each of them reacted promptly to ligation of the limbs. The author does not profess to give a complete explanation for the results of this treatment, and he points out that, the mechanism of acute pulmonary oedema in association with acute nephritis being very imperfectly understood, it is practically impossible to explain how this treatment acts; but he ventures the guess that its action depends on interference with the distribution of the circulating blood and on strain being taken off the heart. He compares this procedure with venesection, which has also been recommended for pulmonary oedema in strong and well-nourished patients, and he notes that though the success of both devices probably depends on the same factors, the former is to be preferred as it can be practised in every case, irrespective of the patient's general health. Ligation of the limbs is also to be preferred because it can, if necessary, be repeated frequently.

482. Pericarditic Pseudo-pneumonia in Children.

LEWIS (*Med. Record*, February 25th, 1922) discusses the signs of apparent consolidation at the left scapular angle which is associated with pericarditis with effusion (pericarditic pseudo-pneumonia). Nearly every case presenting this sign either had acute articular rheumatism on admission or gave history of an attack a few weeks prior thereto. Physical signs vary from distinct dullness extending from the scapular spine to the left base to a very limited area of dullness at the left scapular angle or extending to the axillary line, but over the corresponding dull area distinct bronchial breathing and bronchophony are present. These signs are easily mistaken for a lobar pneumonia, whereas they appear to be due to compression of the lung by the heart, or by a pericardial effusion, and not to any pulmonary exudate. They seem to have very little influence on the course of the disease, and they disappear with the improvement in the pericarditis. Notes of four cases are given, in two of which, in addition to other evidence, x-ray examination showed pericardial effusion without any signs of consolidation in the left lung, and in none of them was there any sign of pleural effusion.

SURGERY.

483. The Thomas Knee-splint in Leg Injuries.

PEARSON (*Med. Journ. of South Africa*, January, 1922) observes that of all surgical advances which we owe to the war, that in the treatment of bone and joint injuries ranks first; and of all surgical appliances the Thomas splint came into its own. Before the war this splint was rarely used for anything but tuberculous conditions of the joints. Though used by Thomas himself, and by Sir Robert Jones and his followers, for treating fractured femurs, it took the great war to convince the rest of the world as to its uses. It was used in 1916 for transport purposes, and was so successful that the long Liston splint was at once discarded. One of the early difficulties in the use of this splint was that the ring, instead of taking pressure against the tuberosity of the ischium, would persist in slipping up and cause ulceration in the perineum. This was easily remedied by suspension of the ring, which prevented it from slipping. In cases under treatment in hospital, by using a hinged knee-flexion piece early movement of the knee can be carried out in cases of fractured thigh. Then, again, there is the ambulatory form of the Thomas knee-splint, suitable for the convalescent stage of fractures of the leg and thigh. It is possible for the patient

to walk about whilst the newly formed bone is still weak. If this splint were adopted as a routine practice much disappointment would be saved to patients and surgeons on discovering some months later that the bone recently joined in good position was now bent perhaps at a right angle. In this splint the side-bars are cut off at the lower end and fit into holes through the heel of the boot. The splint is slightly longer than the limb, and so the leg takes no weight, but simply hangs in the splint. In fractured femur cases such a splint should be worn for three months after getting out of bed.

484.

Pyelitis.

BERLIN (*Med. Record*, April 8th, 1922) considers that the anatomical and postural environments of the kidneys are the chief predisposing factors in the production of infections of the kidney pelvis, and that auto-intoxication and auto-infection following general or local intestinal stasis, or other pathological conditions, are the immediate cause by way of the blood stream. In treatment the most direct and effective results are obtained by intravenous injection of 20 grains of hexamethylenamine, or 20 c.cm. normal saline solution containing 28 grains of sodium iodide, and 1/8 grain each of creosote and guaiacol. In the blood stream, and especially during their elimination by the kidneys, these substances exercise a pronounced therapeutic action on infections of the kidney pelvis. Five cases are quoted in which the treatment resulted in cure, in two of which the Fowler operation for suspension and correction of the postural environment of both kidneys was done on account of the tendency to recurrence, such surgical intervention being advisable only when the condition persists, or tends to relapse in spite of treatment. By rotating the long axis of the kidney from the perpendicular, through an arc of about 90 degrees, to approximate to the horizontal, the outlet of the pelvis points directly downwards, thus securing free and unobstructed drainage, and thereby eliminating a predisposing cause of pyelitis.

485.

Treatment of the Appendix Stump.

GALAGUIER (*Bull. et Mém. de la Soc. de Paris*, February 14th, 1922) states that it is difficult to say by whom the idea of burying the appendix stump was first brought forward. In the early operations no surgeons employed this method. Originally he carefully removed the mucous membrane with a curette, cauterized the stump, and then closed the opening with a catgut suture. To prevent adhesions and for greater security he tried to cover in the stump with a layer of peritoneum or an appendix epiploica. In spite of these precautions post-operative suppuration often occurred, and about the second week a large abscess developed; after evacuating this the patient rapidly recovered. These accidents became less frequent when the stump was sterilized and buried in a fold of the caecum, and as the burial of the stump was perfected so the appendix stump should be buried in the caecum is inflamed, thickened, and oedematous, and when there is peritonitis, this may not be possible. In carrying out this procedure certain points are of importance: the sutures should be placed close round the base, and so not leave a space for organisms from the mucosa to collect and grow; the sutures must not perforate the caecal wall—this is a mistake not always easy to avoid if the caecum is distended and thinned; it is bad practice to tear or bruise the caecal wall with forceps or large needles; the intestinal serosa is very delicate, and should be damaged as little as possible. Another point is that when the appendix has been tied close to the caecum and is cut, a drop of fluid may escape and cause suppuration later. This can be avoided by previously crushing the organ. The caecum is used to divide the appendix, and the surroundings are protected with swabs. These details are of importance, for in a quiet operation no point should be neglected which will guarantee success. The technique of burying the stump should leave nothing to chance.

486.

Cerebral Injury and Cranioplasty.

YOUNG (*Glasgow Medical Journal*, March, 1922) records a case of head injury and damage to the brain where a bone-graft of the skull was later performed. The patient was struck on the head by a steel plate and fell a distance of 40 feet. An extensive depressed fracture of the right parietal region was found, damaging the brain. After the operation left hemiplegia was noticed; this later improved, and after two months he left hospital quite recovered except for slight weakness of the left hand. A year later he came back with a view to closure of the gap in the skull; he then suffered from headache, giddiness on stooping, and a bad memory. The wounds were healed over the area free of bone, which measured 2 by 1½ inches. There was slight facial paralysis, and grip in the left hand was less powerful than in the right;

finer movements could not be performed and recognition of space was defective; the reflexes on the left side were exaggerated. A bone graft was taken from the tibia and fixed in the gap, all scar tissue being dissected away and the bone edges freshened: the adherent brain tissue from under the flap was freed with some difficulty. After the operation there were twitchings in the left face and arm; these ceased when morphine was given. The later history shows that the cranial vault is complete and the giddiness has been stopped, and there has been improvement in the headaches and the tenderness of the scalp. There has been no improvement in the left hand, as one would expect, no effect being produced on the damaged brain tissue itself. The case is interesting as it shows the results of bone grafting in the skull where the brain has been injured.

487. Osteomyelitis of the Superior Maxilla in Infants.

MARX (*Brit. Journ. Ophthalmol.*, January, 1922) calls attention to the eye symptoms due to osteomyelitis of the superior maxilla in infants. Of 35 recorded cases, 30 developed definite eye symptoms, which were the first to attract attention, and hence the importance from an oculist's point of view, since it may rest with him to first arrive at a correct diagnosis. Swelling of the eyelids is usually the first symptom noticed, with swelling and redness in the region of the lacrymal sac, and frequently followed by fistula caused by the tendency of the pus to collect in the ascending branch of the superior maxilla, and eventually finding exit at the inner corner of the eye. The lacrymal sac itself is apparently unaffected, and treatment for abscess formation should be through the palate and processus alveolaris rather than by incision in the lower eyelid, a complete cure resulting without risking an ugly scar and ectropion. Conjunctivitis, another sign of collateral oedema, is a further symptom almost always present, and exophthalmos occurred in 10 of the 35 cases, this being apparently due to purulent exudation in the eye socket following inflammation of the ethmoid cells; it was relieved by incision.

488. Extraction of Foreign Bodies from the Brain.

SATVE (*Bull. et Mém. Soc. Chir. de Paris*, April 4th, 1922) reports five cases of intracranial foreign bodies treated by secondary extraction, with recovery of all the patients. In three cases fragments of shell were removed, whilst on two occasions revolver bullets were extracted. The indications for operating on these cases were: complete aphasia, epilepsy, eye symptoms, and in two cases persistent fistulae, one being associated with hemiplegia. The time after injury when operation was performed varied from thirteen days to ten months. The technique adopted was as follows: under general anaesthesia a small trephine opening was made, the dura mater opened, and under screen examination the foreign body was caught with forceps in the brain. The foreign bodies were all fairly superficial, the deepest lying at a depth of 5 cm. In cases where infection was expected a drain was placed in the brain substance. All the patients recovered from the operation. With regard to end-results, a sufficient time has not elapsed since the operation to estimate the real value of their condition. However, several cases show an improvement of their previous nervous condition. The aphasia in one case has disappeared, whilst no epileptic fit has occurred for three months in the second patient. Operation has not improved the man with hemiplegia, whilst the patient with eye symptoms is better.

OBSTETRICS AND GYNAECOLOGY.

Galactocoele.

389. GRYNFELT and TZELEPOGLOU (*Gynecol. et Obstet.*, iv, Nos. 3 and 4), in an exhaustive study of the literature, have been able to trace only 73 cases of galactocoele; it is probable, however, that many cases elude surgical recognition or intervention. They conclude that galactocoele does not constitute a definite morbid entity and that its appearance should be regarded as an epiphenomenon appearing in diverse pathological conditions. Galactocoeles, which are more often multiple than single, may intercommunicate; they may be classified anatomically in four groups: In ectatic galactocoele the tumour consists of a dilated lactiferous duct; this variety is particularly rare and many of the reported cases rest on doubtful evidence. Interstitial galactocoeles consist of an effusion of milk encysted in the mammary connective tissue and are characterized by absence of elastic fibres around their wall. Adenogalactocoeles constitute the commonest form; an accumulation of more or less normal milk is found in the pathological cavities which occur in a fibro-adenomatous breast. Pyo-

galactocoeles consist in simple chronic abscesses into which lactiferous ducts open and convey milk. The contents of galactocoeles may consist of pure milk, but contents resembling whey or butter, and even "milk-stones," have been described. Microscopical examination shows the presence of colostrum corpuscles; chemical examinations have been made in few cases and have sometimes shown an absence of lactose. In the genesis of galactocoeles two etiological factors are concerned, of which the second is the rarer: inflammatory changes, which according to their situation, intensity, and duration lead to different forms; and traumatism, which determines a rupture of the milk ducts and leads to interstitial galactocoele. Pregnancy and lactation predispose to formation of galactocoele, which may also appear in the newborn or at puberty. Clinically the onset may be acute or chronic; the tumour is usually unilateral, is mobile within the breast and over the subjacent muscles, is usually found to show irregularities of contour, and is only exceptionally fluctuant. The frequent association of galactocoele with fibrocystic disease should lead to some reserve with regard to prognosis. As to treatment, punctures are apt to be followed by prolonged leakage, which leads to risk of infection; excision is the method of election, but voluminous polycystic galactocoeles may require amputation of the breast.

490. Radiotherapy for Cancer of the Cervix.

BURROWS (*Journ. of Obstet. and Gynaec. British Empire*, 1922, 29, 1) treats advanced cancer of the cervix by introduction high in the cervical canal of about 50 millicuries of radium emanation screened by 1 mm. of silver, and by inserting at the same time into or about the growth six smaller tubes of 15 millicuries screened by 0.3 mm. of brass; this is done under general anaesthesia, and the tubes remain for twenty-four hours. Another method consists in combining the use of the large central tube with the insertion in the surrounding tissues of small unscreened capillary glass tubes each containing 2 to 7 millicuries of radium emanation; the large tube is removed after twenty-four hours. Daily douching should be performed after the operation. Apart from extremely advanced cases, the least favourable results are to be expected in the case of very large and very hard growths, those with extensive infiltration of the vaginal walls, and in patients under 40. Adhesion to the bladder by no means renders the case hopeless. The production of a recto-vaginal fistula is uncommon, being little more frequent than in untreated cases. Of 100 advanced cases treated by the writer, about 15 appeared to be well at the end of twelve months, 6 were rendered operable, and 6 appeared well after periods of three to four and a half years.

491. SEITZ (*Klinische Wochenschrift*, April 8th, 1922) remarks that the data are at present insufficient for a decision as to whether treatment of cervical cancer by operation or by radiotherapy is better, but that it may now be justifiably laid down that to discard the former for the latter is a permissible line of treatment. Quoting the figures of Wintz and Seitz (20.7 per cent. of five years' cures among 58 cases of cervical cancer of all degrees of operability), he points out that such results correspond fairly closely with those of Wertheim's extended hysterectomy. The cases of Wintz and Seitz received combined radium and x-ray treatment, of which the efficacy was probably due, it is said, chiefly to the latter. Seitz reports two years' cures, numbering 56 per cent. and 53 per cent. respectively, among 67 cases of cervical cancer treated by combined x-ray and radium therapy, and 34 treated exclusively by x rays. In post-operative radiotherapy the writer prefers to give large doses.

492. DÖDERLEIN (*Munch. med. Woch.*, 1922, 7) reports the fate of his cases of cervical cancer treated by applications of radium or mesothorium five years ago. Of cases which could be classified as operable 48 per cent. showed apparent cure after five years, of borderline cases 20 per cent., and of cases with widespread infiltration 36 per cent. Taking into consideration those patients only who did not abstain from undergoing the full course of treatment advised, he found percentages of five years' cures amounting to 81 per cent., 36 per cent., and 11 per cent. in the respective groups. The importance of early diagnosis of cervical cancer by the general practitioner is again emphasized.

493. Pregnancy Toxaemia and Uterine Sepsis.

KELLOGG (*Amer. Journ. of Obstet. and Gynecol.*, April, 1922), from an analysis of hospital statistics, draws the inference that, irrespective of the mode of delivery, patients suffering from pregnancy toxaemia are more prone than others to septic uterine infection during or after labour; this is especially the case in those toxæmic patients who have suffered from convulsions. Of the control series, 2.5 per cent. showed evidence of sepsis, of patients with toxæmia but

without convulsions. 14 per cent., and of those suffering from toxæmia associated with convulsions 25 per cent. The practical conclusions drawn by the writer are that it is wise to abstain whenever possible from the performance of Caesarean section, vaginal or abdominal. It is preferable whenever progress is being made in cervical dilatation (with or without the aid of a dilating bag) to let labour terminate spontaneously or by a low forceps operation. When dilatation is not observed after introduction of the bag recourse must be had to vaginal Caesarean section or manual stretching of the cervix. Profuse catharsis favours uterine sepsis; as suggested by De Lee, salts should be withheld until after delivery, or, if they have been given, the rectum should be closed (until just before delivery) by a circular suture.

PATHOLOGY.

494. The Intradermal Reaction in Experimental Tuberculosis.

DEBRÉ and BONNET (*C. R. Soc. Biologie*, March 4th, 1922) bring forward evidence to suggest that the local reaction of the guinea-pig to an intradermal injection of tuberculin—the animal having previously been infected with living tubercle bacilli—varies more or less directly with the resistance of the animal. They find that a dose of 0.5 mg. of living tubercle bacilli determines the death of a guinea-pig weighing 400 to 500 grams in five to seven weeks, that of one of 500 to 600 grams in ten to fourteen weeks, and that of one of 700 to 800 grams in sixteen to seventeen weeks. Also that the local reaction and the swelling of the lymphatic glands draining the site of injection are more pronounced in the heavier than in the lighter animals. Further, in the heavier animals the health remains good till just shortly before death, while in the lighter ones there is a progressive loss of weight almost from the start. At autopsy the former animals are found to have a local lesion in process of cure, marked regional lymphatic swelling, large tubercles in the liver and spleen, and a confluent bronchopneumonia; in the latter group, however, the local and lymphatic lesions are minimal, while a generalized tuberculosis is manifest throughout the body. Now, if intradermal reactions be made on infected guinea-pigs of varying weights, it is found that the intensity of this reaction is directly proportional to the intensity of the local reaction following the injection of the bacilli, and that the persistence of the intradermal reaction is longer in proportion as the weight of the animal is heavier. These results are in close accord with what is found in human infants. In weakly, poorly nourished infants the evolution of tuberculosis is accompanied by a progressive loss of weight and a practical failure to respond to the tuberculin reaction, while in healthy, breast-fed infants fever persists to the end and the tuberculin reaction is very marked.

495. Cultivation of *Spirochaeta obermeiri*.

KLIGLER and ROBERTSON (*Journ. Exper. Med.*, March, 1922) have successfully cultivated the spirochaete of relapsing fever in the following medium: horse or rabbit serum, diluted with one or two parts of saline, plus 1 per cent. peptone. The reaction is adjusted to pH 7.2 and the media distributed in quantities of 3 to 4 c.cm. into tubes approximately 1 cm. in diameter. The tubes are inoculated with one drop of infected blood and covered with a layer of oil 1.5 cm. high. When subcultures are being made a drop of fresh rabbit's blood must be added to supply the necessary fibrin, or 0.1 per cent. agar may be used instead. Growth must be started at 28° to 30° C., but later growth proceeds satisfactorily at room temperature. By this technique the authors succeeded in maintaining cultures for three to seven weeks and in carrying them on in successive subcultures by transplanting regularly at intervals of two to four weeks. There are certain details, however, with regard to the constituents and reaction of the medium which must be carefully attended to. Dilution of the serum does not impair its nutritive properties and the addition of animal tissue, such as kidney, is unnecessary, but growth activity is much increased by the presence of a small amount of agar or fibrin, in the meshes of which the spirochaetes are found most abundantly. The optimum spirochaetes are found most abundantly. The optimum reaction for growth is a pH of 7.2 to 7.4, and the reaction limits for survival are between 6.8 and 8.2. Since the fluids used for the cultivation of the spirochaete become progressively more alkaline on exposure to air, in order to stabilize loss of CO₂, it is necessary after standardizing the culture. This was achieved in Noguchi's case by the addition of sterile kidney, which gives off CO₂ and of autolysis which neutralize the increasing alkalinity; but the authors recommend as a more reliable procedure

addition of 1 per cent. peptone broth or egg albumin as a buffer, and the covering of the culture with a layer of oil. Since *Spirochaeta obermeiri* is a strict aerobe, the oil layer should not exceed 1.5 cm. in height, in order to permit adequate aeration.

496.

Fusiform Bacillus Bacteraemia.

LUSSANA (*Pathologica*, February 1st, 1922) remarks that though Vincent's angina is a well-known condition, the other morbid processes due to the fusiform bacillus have received little attention. He records the case of a man, aged 26, who was operated on for a pulmonary abscess in the left lower lobe, in the pus from which the fusiform bacillus was found. Subsequently symptoms of an endocranial lesion developed, and at the autopsy a cerebral abscess containing fusiform bacilli was discovered in the left occipital lobe. Lussana's conclusions are as follows: (1) There is a bacteraemia due to the fusiform bacillus which originates not in the fauces but in the lungs. (2) Animal inoculations show that the fusiform bacillus in symbiosis with pyogenic cocci possesses a moderate virulence which diminishes after transmission through a series of animals. (3) A consequence of this bacteraemia is the development of metastatic abscesses in which the fusiform bacillus is found in combination with spirilla or cocci, but never in pure culture. (4) In some of the suppurative processes due to the fusiform bacillus, however extensive and grave their anatomical condition may be, the symptoms develop very insidiously, without much fever, as in Vincent's angina. The bacteraemia due to the fusiform bacillus may even escape recognition and not become manifested until symptoms are caused by localization of a suppurative focus at some distance from the portal of entry of the fusiform bacillus. This is probably the reason why a larger number of cases have not been identified.

497.

Acquired Resistance to Cancer.

NAKAHARA (*Journ. Exper. Med.*, April, 1922) has proved that it is possible to render mice resistant to transplanted cancer by the previous injection of olive oil. Bashford showed that resistance to transplanted cancer could be induced by inoculation of homologous living tissues; later, Murphy established the fact that resistance could be induced by the use of suitable doses of x rays and intense dry heat. In each of these cases there are certain associated manifestations—namely, a latent period after the injections during which there is no evidence of resistance, a local cellular reaction about the inoculated cancer graft, an increase in the number of circulating lymphocytes, and a marked increase in the proliferative activity of the lymphoid organs. Precisely similar phenomena were found to be associated with the increased resistance to cancer following intraperitoneal inoculation with olive oil. Here also the injection of the oil was followed by a latent period, which in its turn was succeeded by a more resistant period, the maximum degree of resistance appearing about the tenth day. The most marked lymphoid proliferation was found following the intraperitoneal inoculation of 0.2 c.cm. of oil, and this was found to be the dose conferring the highest degree of resistance to mice. There are strong reasons for attributing this increased resistance to the activities of the lymphoid cells. Thus, this state of resistance has been found to be preceded by a proliferation of the cells of the lymphoid germ centres; in the resistant animal the neighbourhood of the inoculated cancer graft becomes infiltrated with lymphoid cells, and finally the circulating blood shows a large increase in lymphocytes.

498.

The Mechanism of Infection with Cholera.

This is the question dealt with by MASAKI (*C. R. Soc. Biologie*, March 11th, 1922). If a guinea-pig be given a dose of living cholera vibrios either intraperitoneally or subcutaneously it dies, and in each case the vibrios can be recovered from the intestinal contents. In their passage through the animal they invade the blood stream and are excreted thence into the gut. In other words, the intestine appears to have a specific affinity for the organism, and it is owing to the susceptibility of the intestinal mucosa to the toxin of the vibrio that the animal dies. If, however, the vibrios be given by the mouth, even in enormous numbers, they exert no effect and the animal remains perfectly well. By previously sensitizing the animal with bile it can be shown that administration of the vibrios calls forth the presence of protective antibodies, though no corresponding appearance of protective antibodies can be demonstrated. Yet in spite of the lack of these substances the animal is immune to inoculation with living vibrios given directly into the blood stream. The only explanation offered for the presence of this immunity is that it must depend not on the properties of the serum but on a definite local acquired insusceptibility of the intestinal cells to the toxin of the organism.

An Address ON THE DIAGNOSIS OF HYSTERIA.*

HENRY HEAD, M.D., F.R.S.,
CONSULTING PHYSICIAN, LONDON HOSPITAL.

Our knowledge of the nature and causes of functional nervous disorders has been revolutionized during the last fifteen years, and more recently the prevalence of the war neuroses has aroused a widespread interest in morbid psychology. Rival theorists contend for the truth of dogmas they have elevated to the solemn position of a religious cult. Moreover, the treatment of the functional neuroses has become a special branch of medical practice carried out by men who see comparatively little of organic disease. At the same time the general physician is scarcely familiar with the psychological aspect of medicine; he and his colleague, the surgeon, rarely consider how large a part the mind plays even in the symptoms of gross structural disease.

But there is one series of phenomena where a knowledge of morbid psychology is of profound importance to every medical practitioner; for no branch of medicine is free from the puzzling manifestations of hysteria. Moreover, during the intensive study of the ultimate causes underlying the functional neuroses, in which group hysteria plays so important a part, many points of diagnostic importance are liable to be forgotten. Much of this knowledge is traditional and cannot be found in textbooks; and yet it may become at any moment of fundamental importance to every medical practitioner, however small his interest in the neuro-psychoses. For hysteria is mainly associated with abnormal physical conditions. In fact, it might be defined as a morbid mental state, accompanied by physical manifestations and certain forms of aberrant conduct.

These physical signs are as definite and specific as those of any other disease. Hysteria is sometimes said to "imitate" organic affections; but this is a highly misleading statement. The mimicry can only deceive an observer ignorant of the signs of hysteria or content with perfunctory examination.

For the diagnosis of hysteria it is necessary, not only that there should be no demonstrable organic cause for the symptoms, but that the positive signs of hysteria should be present. It is to these positive signs I am anxious to call your attention; but nothing could be duller than a category of the protean conditions which may accompany this disorder. I shall therefore enumerate and describe them solely in order to lay bare to you the means by which they can be detected and the state of mind which underlies their appearance.

Freud described hysteria as a "conversion neurosis." This term has been widely adopted, and signifies that the conflict in the patient's mind is solved by some aberrant reaction, which removes him from the situation of doubt and anxiety. If a soldier, unable any longer to face the horrors of the front, became paralysed in both legs, he was automatically relieved from the necessity of facing danger without the ohloquy of running away.

Physical Signs of Hysteria.

Disorders of speech were amongst the commonest hysterical affections due to the strain of war. Sometimes the patient became completely mute, although he wrote voluble accounts of his condition and understood perfectly what was said to him. This is an example of that peculiar disintegration of some highly developed function so characteristic of hysteria. It is not the physiological mechanics of language that are affected, but the patient is imbued firmly with the idea that he cannot speak; this is no reason, however, from a conceptual point of view, why he should not be able to comprehend what is said to him, to read, or to write—a condition impossible from organic disease. Although his voice might be reduced to a whisper, he could cough loudly; for from a psychological point of view the resonant sound of a voice is not so much with articulated speech. Moreover, on records are seen to remain widely apart with a cough they close normally.

The so-called "hysterical stammer," more accurately termed a "stutter," exemplifies another aspect of this

disorder. Unnecessary syllables are interjected into the stream of speech; the patient is not held up like a true stammerer by difficulty in reproducing some word beginning with a consonant or labial, but his speech is interrupted by a series of perfectly articulated sounds.

This illustrates the tendency of hysterical phenomena to consist of a positive disorder of movement, which is so clearly demonstrable in the various forms of tremor. Rhythmic unsteadiness, due to structural disease or want of neural control, is shown by defective power to maintain a certain posture steadily. An hysterical tremor, on the other hand, is a positive repeated movement of a high voluntary type, varying in rapidity. It ceases if the patient can be persuaded unwittingly to perform some other movement with the same limb. Thus, a soldier with a severe tremor of the right hand and arm was able to play the banjo perfectly, and I used this musical aptitude for effecting his cure.

Many are the forms of spasm which are liable to appear in hysteria, but they all depend essentially on the assumption of a certain posture. Most of them are local, and affect one limb or even a single joint. Occasionally, both arm and leg may be contracted on the same side of the body, and if the patient does not move them to command, the condition may be mistaken for a hemiplegia. Any attempt to break down a spasm of this kind, to open the closed hand, or to straighten the flexed knee, meets with intense resistance; but in many instances it is equally difficult to alter the position even in the direction imposed by the spasm. If the shoulder and neck are contracted, resistance may be experienced not only in pushing the head towards the normal shoulder, but also in moving it farther in the direction of the affected side.

The so-called paralysis of the tongue is another good example of this rule. On protrusion it deviates, say, to the right; with organic disease this would signify loss of power in the muscles of the right half, and the tongue would in consequence be withdrawn to the left. If the deviation is due to hysteria and the tongue is thrust out to the right, this position is maintained, even when it is returned to the mouth.

Sometimes movement is positively inhibited; the patient says, "I cannot move my leg," and it hangs inert, or is dragged behind him like a log. If, however, he is laid upon the bed and asked to kick his leg into the air, you will be able to determine, by placing your hand under his heel, that it is pressed strongly into the bed. Turn him over on to his face and ask him to bend his leg so as to raise it in the air; you will now find that the leg is strongly thrust downwards. On each occasion he responded to your command by an exactly opposite movement. In the milder examples of loss of power or inability to stand on one leg, the nature of the affection is revealed by the following trick. If it has been determined to the satisfaction of the patient that he cannot support his weight on the right foot, tell him you are quite satisfied that the right is affected, but that the left is his "good leg." When he is standing steadily, give a sudden command, "Kick out your good leg"; this he will do, although it necessitates balancing himself upon the affected foot. On the other hand, follow this quietly with the order, "Kick out your bad leg," and he will fall, although he is supported on the normal limb. Sometimes the patient is completely unable to stand or to walk, but judicious examination demonstrates that he can make all the necessary movements when lying on his back.

Inco-ordination of movement, apparently due to lack of recognition of the posture of the affected limb, is a not uncommon manifestation in hysteria; but it usually differs fundamentally from ataxy of organic origin. Suppose a cerebral lesion has made it impossible to touch the nose with the forefinger of the right hand, when the eyes are closed, you will find that the normal (left) hand has, as a rule, greater difficulty in finding the tip of the affected forefinger than vice versa; for it is the position of the right hand which is unknown, and it is this which leads to the difficulty. The defect is the opposite in hysteria; for since no good action can be carried out by the affected part, the right (affected) forefinger makes wild attempts to find the left hand, whereas the normal hand is rapidly brought correctly into contact with the part whose position is nominally unknown.

Again, when the patient attempts to touch his nose with the forefinger, it may deviate widely from the mark and always pass to the same side of the head; but if the head is pushed over in that direction, the finger will now deviate still further, as the goal is brought closer to the position usually reached by the hand.

* Delivered before the London Hospital Medical Society, March 2nd, 1922.

objects are appreciated according to their luminosity and not their chromatic value. Green is said to be "light" or "whitish," red "dark" or "greyish"; this response is heightened by mounting the green object on a black background and the red on a white square twice its size.

During the earliest stages of optic atrophy, for instance in disseminated sclerosis, vision for red and green is frequently diminished and the colour field may be reduced to minute proportions. But outside it still lies a large area of retina, over which these colours are appreciated as "light" or "dark" and the form of the test objects is clearly recognized. In hysteria, on the other hand, they are said to be coloured or are not seen at all, whatever may be the limits of the visual field. This is ample proof that the defect is of mental origin, and experience shows that it is usually suggested by the observer or by his methods of examination. For separate appreciation of luminosity and colour is a physiological phenomenon of which, like the blind spot, we are normally unconscious. But, over a field restricted in consequence of psychical causes, we either recognize or do not recognize an object; vision is not broken up in terms of physiological function, but follows strictly mental lines.

Diagnostically, the visceral manifestations are by far the most misleading. Occasionally the intestines become inflated with gas and simulate a tumour of the abdomen; but such a swelling is resonant to percussion, it does not shift from side to side according to the position of the patient, and the physical signs alter if the head is lifted from the pillow so as to tighten the rectus. If you are in doubt a whiff of chloroform will settle the matter.

Retention of urino sometimes forms a troublesome complication, for it is not wise for you to pass a catheter. Let this operation be performed by a careful and judicious nurse. It is well to remember that incontinence of urine never occurs in uncomplicated hysteria.

Seizures and Fugues.

Not uncommonly the patient falls into a dissociated mental state; memory of the occurrences during the seizure may be absent during the waking condition, and consciousness is therefore supposed to have been lost. Such attacks of alternato consciousness are frequently associated with otherwise inexplicable conduct and during the war were sometimes accompanied by extreme violence. This brings us to those remarkable seizures known as "fugues."

A Lieutenant in the R.F.A. was wounded in France, but the injury was not severe. Whilst in hospital in England he obtained leave to spend a week-end with his parents. On Sunday afternoon he started on his motor bicycle, intending to return to hospital, and disappeared, but was found several weeks later on a farm where he had worked as a pupil before joining the army. He arrived there on Monday morning, occupied his old quarters, and set to work at once. When the surprised farmer asked him how long he intended to stop he said he had been discharged from the army. He subsequently confessed to me that during the ride he began to think with pleasure of his life on the farm; from that time he had only a hazy recollection of what happened, until he was discovered by his brother three weeks later.

* These "fugues" are commonly attributed to amnesia, and the patient is said to remember nothing that happened. This is true in certain instances; but I am convinced that, during some of these inexplicable disappearances, memory is not completely lost, and sometimes a fairly coherent account can be obtained from the patient of how he spent his time. He loses all appreciation of the cogency of the reasons against the line of conduct he adopts, and his personality may have

Limitation of the field of vision at one time occupied an important place amongst the signs of hysteria. But, since Babinski's statement that it is due to suggestion on the part of the examining physician, it has fallen into undeserved disrepute. For the very fact that a condition of this kind can be manufactured in a patient is striking evidence of the nature of the disorder from which he suffers. The normal field of vision consists of a central portion where colours can be accurately distinguished; outside this lies a zone of considerable extent which is colour blind, although all shades from white to black are clearly visible. Here coloured

undergone a subtle transformation. But he can often remember the desires which lay behind his mental conflict, and give some account of his disappearance. Such fantasy building was responsible for many aberrations of conduct in young officers during the war, and lies at the bottom of those curious cases, met with in civilian life, where a woman for a time leads a purely fantastic existence.

Mental Causes of these Physical Manifestations.

When we attempt to express these morbid phenomena in general terms we are struck by their positive nature. There is nothing negative about the manifestations of hysteria; even the anaesthesia is due to refusal to accept impressions, which otherwise run their normal physiological course. Amongst the disorders of motion, the tremor is due to actively repeated movements, rather than to failure of static tone; spasm is the assumption of a definite posture and not the reflex over-activity of some lower function; the so-called hysterical paralysis is the effect of direct inhibition, an active expression of the conviction in the patient's mind—"I cannot move."

Closer analysis of these positive phenomena shows that they depend on three mental factors—proneness to auto-suggestion, a negative attitude to orders from without, and a tendency to the state known as "dissociation." There has been much dispute concerning the extent to which these patients are suggestible; hypnosis frequently fails lamentably to remove their disabilities, in spite of the ease with which a suggestion is accepted that falls in with their morbid state of mind. Many hysterical joint affections start in some remark by the medical attendant, and the nature of the anaesthesia, or the form assumed by the fields of vision, are all examples of antitherapeutic suggestion. Associated with a ready acceptance of some morbid idea by the hysteric is an instinctive opposition to external commands. Place your hand lightly around the arm, so that the fingers cover the biceps and the thumb is in contact with the triceps; tell the patient to bend his arm, and the first muscles to contract are the extensors. Give the opposite order, and instantly the biceps can be felt to tighten. This "negativistic" attitude, as it is called, permeates the whole mental activity of the hysteric. Thirdly, there is a profound tendency to what is called "dissociation." This expression was employed by Pierre Janet to indicate a state in which some aspect of mental activity had become split off from the conscious functions of the mind and lived, as it were, an isolated life. He used the conception to explain not only the lapses of memory, fugues, and dual personality, but also the anaesthesias and hysterical paralyses. Now, there is no doubt that we possess the power of refusing to accept impressions, even under normal conditions. Experts at the direct method of ophthalmoscopic examination keep both eyes open; but the one which is not applied to the back of the mirror is, for the time being, psychically blind. In the same way, when shooting, both eyes remain open, but alignment on the bird is made with the right alone. The hysteric, like the hypnotized person, has this power in a still higher degree. He can shut off all impressions arising from one limb so that they do not disturb consciousness; and yet his reflexes are normal and, with hysterical blindness, he can avoid obstacles in the room. Automatic acts are performed with ease, though voluntary responses are inhibited or obstructed.

If these are the factors in hysteria, how is this remarkable state of mind induced? It is essentially an irrational answer to a conflict. A young woman, who is a candidate for an examination which she feels is too difficult for her powers, can solve the problem illegitimately by spasm of the right hand. A soldier suffering from fear, knowing he cannot run away, finds a perfect and honourable solution in hysterical paraplegia.

But in many cases the underlying cause is far more subtle. Many of you know the evil effects of not answering promptly a disagreeable letter. Perhaps it remains unopened in your pocket, and all day you feel that some unknown misfortune is about to befall you—you are "off your game," you are certain that you are in for influenza, or at least for a bad cold. All these ills are an expression of the unresolved emotion evoked by that unanswered letter.

This is an example of the evil effects of repression, or an attempt to shirk some unpleasant experience by expelling it from consciousness. But fortunately we can sometimes forget even disagreeable facts without harm. In order that repression may produce evil consequences the idea, charged with emotion, must have been thrust out of consciousness; the patient dislikes it with such intensity that he refuses to

face it squarely. The emotion accompanying such an idea may then appear in some substituted form, such as vomiting, headache, or paralysis. If, for example, a patient expresses to you a moral repugnance to taking food, it is well to consider whether her statement does not hide some real cause for moral doubt and anxiety.

Fear is the most potent reason for repression. All children and animals experience fear; this is suppressed in the adult, who, under normal conditions of civilized life, experiences anxiety only. But deep down lies fear, ready to spring into being when inhibition is removed—as, for example, during sleep. Now in civil life fear of disease is extremely frequent. Some are so subject to this form that they dread each disease in turn, as it becomes the fashionable centre of discussion in the popular press. Such fears, dismissed from consciousness without reasonable consideration, are liable to work havoc in the underworld of our minds.

Some relationships are by their very nature liable to be highly charged with emotion: "No man," Bacon said, "can speak to his child but as a father"; and parental fear is the basis of many anxieties. Conversely, however, adoration of a son for his mother, or a daughter for her father, underlies many of the difficulties which may arise subsequently in marriage.

Marriage without physical affection is an impossible human relation; one of the simplest methods of escaping from such difficulties is the development of a physical illness. In the present day many women embark heedlessly on associations that are bound to lead to emotional trouble; the so-called "friendship" with a married man, whose wife "does not understand him," is a state of unstable equilibrium. Fears in women of marital relations, or of pregnancy, can usually be traced back to some terrifying experience in childhood or adolescence.

A very important element in the production of a conversion hysteria is a want of capacity to face failure. The schoolboy craves to save himself from disgrace; the hysteric loads the dice to produce an effect that would have been impossible by honest toil. Hence the frequency of direct malingering—as, for example, the production of fictitious sores. To be interesting is to be endowed with power; a paralysed girl with a charming and modest manner can attract universal attention from the simpler sex.

Treatment.

I cannot close this discourse without saying a few words about treatment. If possible, the patient should be removed from the usual surroundings and new influences brought to bear. An attempt should be made to switch the dissociated part into the continuity of the patient's mental life. Every form of persuasion should be exercised to convince the patient that he is able to carry out the action he is convinced to be impossible. Never humiliate him or accuse him of dishonesty. No one is a greater failure than the medical officer who wishes all hysterics could be shot at dawn. On the other hand, the firm diplomatist with subtle and demonstrable reasons why the patient can stand, walk, or feel, often produces miraculous cures. But it must never be forgotten that in a large number of cases, especially in civil life, removal of hysterical symptoms is only a prelude to the discovery of an anxiety neurosis. The causes for the suppressed emotion must be investigated, or the patient may be left in an even worse condition than that in which you found him.

To the medical man I would say, see that you do your patient no harm by antitherapeutic suggestion; carefully prune your conversation, and do not think out your diagnosis aloud. Purge your mind of vague phrases, and avoid such words as "neuritis." Some diagnoses, such as "floating kidney," are more deadly than the disease. Avoid thinking in terms of surgery when dealing with functional neuroses. When you find that a patient is vomiting, do not let your mind at once leap to gastro-enterostomy. Be natural, but on guard; you will then be ready to deliver your blow at the moment required. At the same time, remember that your most brilliant conversation is useless with an hysteric; she is interested in herself, not in you.

Nature's moral code, under which we work, is cruel and unrelenting. There is no forgiveness of sins; but, in the medical man, this knowledge should be tempered towards the patient by clinical curiosity and human sympathy. In conclusion, I would say to all who have to deal with these morbid conditions, be as honest in thought as you would be naturally in deed. Act without fear and never lose courage; finally, call nothing common or unclean.

A Lecture to Graduates

ON

THREE YEARS OF PELVIC SURGERY.

DELIVERED AT THE MANCHESTER ROYAL INFIRMARY,

BY

W. E. FOTHERGILL, M.A., M.D., C.M.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, VICTORIA UNIVERSITY
OF MANCHESTER.

DR. C. P. BRETNALL, Resident Surgical Officer to the St. Mary's Hospitals, Manchester, and Dr. W. E. Powell, Senior House-Surgeon, Special Departments, Manchester Royal Infirmary, have been kind enough to enumerate and analyse the cases on which I have operated personally at the St. Mary's Hospitals and at the Manchester Royal Infirmary during the last three years. Their figures deal with 1,354 consecutive operations, and show the relative frequency with which common pelvic lesions occur, and indicate the measure of success which may be expected when these lesions are dealt with by surgical methods. The figures also bring out certain debatable opinions and illustrate certain points of view which form interesting subjects for discussion. I thank my two colleagues for the time and care they have bestowed on this analysis, which I propose to bring before you with brief comments on the methods used and the results secured.

Pelvic Infections.

During the three years there were 82 cases of pelvic infection. Of these, 5 were operated upon during the acute phase by the vaginal route, drainage being secured through the floor of the pouch of Douglas. In the other 77 cases the abdomen was opened after waiting until the pulse and temperature had been normal for some time. In 35 of these 77 cases the body of the uterus was removed together with both appendages, while in the remaining 42 cases the injured organs alone were removed, the uterus, one ovary, and one tube being conserved. Drainage by the lower angle of the abdominal incision was used in 13 of the 77 cases. There were no deaths amongst these 82 cases of severe pelvic infection, nor were there any unpleasant sequelae, such as the formation of faecal fistulae. This success I attribute to two factors. First, the results of infection have a natural tendency to recovery. They are not progressive diseases like new growths. Inflammation is not a disease, but a curative process. If judiciously helped by the surgeon it will generally save the patient, though it may be at the cost of her reproductive function. Secondly, in these cases the abdomen was only opened after the acute inflammation was over, the vaginal route being chosen whenever it was really necessary to let out pus during the continuance of constitutional disturbance. Some of you may be horrified to hear that the uterus and both appendages were removed in 35 out of 77 cases. But a uterus without ovaries is no use, and, if left isolated in the middle of the pelvis, with its blood supply impaired, it often becomes a source of trouble. It is best to remove everything except the cervix unless it is possible to leave a fairly sound uterus, one fairly sound ovary, and one fairly sound tube—in short, a working set of reproductive organs. The 35 patients that have suffered the radical operation have their menopause behind them, and will be healthy and comfortable as to the pelvis for the rest of their lives. As to the 42 other patients, some of them may certainly have children; but, on the other hand, some of them are sure to have recurrences of infective trouble with disability, discomfort, and further surgical intervention.

Pelvic Growths.

In 200 cases "fibroids" were the leading feature. One tumour proved to be a sarcoma and one an adenomyoma. Cancer of the cervix complicated one case and cancer of the body another; while small ovarian cysts were present in 13 cases. Nine of the myomata were cervical in position, many of them were degenerated, and several were infected, one patient having general peritonitis on admission. One sloughing myoma was removed in small pieces by the vaginal route, the abdomen being opened in the other 199 cases. Panhysterectomy was done 10 times; supravaginal hysterectomy 180 times, myomectomy 7 times; while in two cases the growths could not be removed. In these 200 cases there were six deaths:

1. General peritonitis on admission; drainage only.
2. Ill after five years' bleeding; abdomen reopened for partial obstruction; no cause found.
3. Fibroid in broad ligament; shock; died the same day.
4. Extreme anaemia; recovered from operation; died some weeks later from anaemia.
5. Embolism tenth day.
6. Uterus contained a dead ovum; pelvic sinuses thrombosed; embolism third day.

Panhysterectomy was done only when the myoma was cervical and in the case complicated by cancer of the cervix. I regard the occurrence of cervical cancer after supravaginal hysterectomy as a mere coincidence. If the cervix should be removed because a woman has a myoma, surely several other parts of her body which are prone to cancerous change should also be taken for the same reason. In operating for myoma I generally follow the guiding principle of leaving nothing but the cervix, unless it is possible to leave a working set of reproductive organs. It is difficult to leave ovaries with their blood supply unimpaired. There is evidence that ovaries left *in situ* do not persist more than a couple of years, and that they often become the site of pathological changes. A woman can only have one menopause, and I prefer that she should get it over just after her operation rather than two years or so later. The surgical menopause is regarded with undue apprehension, and J. W. Bristow's² investigations show that there is nothing solid to be gained by leaving ovaries when the uterus is removed.

The present series contains only 25 cases of cancer of the cervix, as during the last three years I have been referring a great many of these cases to Dr. A. Burrows of the Manchester Radium Institute. Of the 25 cases 12 were inoperable and received palliative treatment by curette and cautery. The other 13 cases were dealt with by abdominal total hysterectomy. There were no deaths and no unpleasant sequelae. The cases were carefully selected, and we hope that some of them will pass the test of freedom from recurrence for five years. There were 23 cases of cancer of the body. All of them were attacked by the abdominal route, and satisfactory total hysterectomy was completed in 21 cases. The prognosis is five times as good as in cancer of the cervix. There were three deaths:

1. From exhaustion, fourth day.
2. From paralytic ileus, third day.
3. Radium put in parametria at time of incomplete operation; healing, but died from exhaustion on the eighteenth day.

There were 14 patients who were found on abdominal section to be the subjects of ovarian cancer, primary so far as could be ascertained. Most of these patients had a quantity of free fluid in the abdominal cavity (hydroperitoneum). Removal of the growths was attempted in each case, but was found to be impossible in five instances. Of these 14 patients, 5 died of exhaustion before leaving hospital. It may be asked if operation in these cases is justified. There are three reasons for it. First, the removal of a malignant ovary often gives considerable relief during the remainder of the patient's life. Second, in certain cases, in spite of a laboratory diagnosis of malignancy, there is no recurrence at all. Third, without opening the abdomen it is often impossible to make a complete diagnosis. For a uterine myoma, a fibroma of the ovary, or an ovarian cyst, if its blood supply is impaired, may bring about the appearance of free fluid in the peritoneal cavity. Cases with hydroperitoneum, therefore, should not be tapped, but should be submitted to exploratory incision. If this is always done a considerable percentage of the patients can be saved.

Simple cystic and solid growths of the ovary and broad ligament amounted to 114 cases. One of these had general peritonitis on admission and was treated by drainage only. The growths alone were removed in 97 cases, both appendages together with the body of the uterus being removed in 16 cases. Here, as in other conditions, the rule was followed of leaving nothing but the cervix, unless a working set of reproductive organs could be retained. There were four deaths after the 114 operations:

1. Dermoid cyst and fibroid; adhesions; abdomen reopened fourth day for signs of obstruction; no cause found; died the same day.
2. Patient aged 82; admitted for intestinal obstruction; healed well after removal of large cyst; died twenty-third day, intestinal paresis.
3. Two solid ovaries; bronchopneumonia.
4. Suppurating ovarian with peritonitis on admission; drainage only.

Other Pelvic Disorders.

There were 59 cases of retroversion considered to require operative treatment, and dealt with by means of Webster's sling. I find this to be the most satisfactory of the 87 operations which have been devised in recent years for the correction of retroversion. Many of the cases were complicated by the results of old pelvic infection, and in several dyspareunia due to prolapsed ovaries was the leading indication for treatment.

Uncontrollable bleeding at the menopause was treated by supravaginal hysterectomy in 10 cases, which, I am given to understand, could have been dealt with successfully by means of radium. There were also 13 cases of ectopic gestation requiring salpingectomy, and remarkable only because they included no example of rupture with haemorrhage demanding "urgency" operation.

Further, there were 23 unclassified abdominal sections whose consideration is outside our present purpose, interesting as many of them were. They included an inverted uterus, a double uterus, a sequestered ovarian adenoma implanted on the rectum, diverticulitis, a renal sarcoma adherent to an inflammatory mass in the pelvis, a cyst of the common bile duct, desmoid growths of the abdominal wall, various cases of hydroperitoneum of obscure origin, and various cases of tuberculous peritonitis involving the genital organs. There was no case of primary genital tuberculosis.

Review of Abdominal Operations.

Thus there were 545 abdominal sections in all, and the deaths were 18 in all—that is, 3.3 per cent. It is clear that the mortality could be kept lower than this by selecting the cases; but if operation is undertaken whenever it is thought that life may be prolonged or that suffering may be relieved, a number of post-operative deaths must occur. A careful study of the notes of the 18 patients who died brings out a striking fact which is not always kept in mind. Only three of the eighteen were in ordinary good health when they came for treatment. The other fifteen had been injured by prolonged bleeding, by infections and degenerations, or were the subjects of malignant disease. The three healthy persons died from shock, embolism, and pneumonia respectively. In the other fifteen, pathological factors had been at work before treatment was sought. The lesson is that the removal of lumps from the pelvis and abdomen is like making a will—it should be done in time of health. Three deaths in 545 is $5\frac{1}{2}$ in 1,000, and we know that four deaths occur in 1,000 cases of labour. Thus, when a woman is in good health, she can have a simple uterine or ovarian tumour removed with little more risk and with much less discomfort than that involved in having a baby. But with delay up go the risks. No pelvic lump can be guaranteed to remain in a healthy condition; and if the patient declines to part with one in time of health the responsibility should rest on her and not on her medical adviser.

Vaginal Operations.

Passing on to the cases in which vaginal operations were done, there were 406 cases of gonital prolapse. These were treated by methods which I have sufficiently described elsewhere, and all left hospital soundly healed. F. H. Lacey's recent investigation¹ of my 1914-15-16 cases of prolapse shows that permanent cure was obtained in 97 per cent. of them. There were also 112 cases of rupture of the perineum and recto-vaginal fistula, who were all discharged cured. The urinary fistulae numbered 16 and were cured with one exception, which requires further treatment. The whole vulva was excised seven times for cancer and once for leucoplakia, and these operations, with those previously mentioned, make up 560 classified vaginal operations.

There were also 249 smaller vaginal interventions, including cases of haematoecolpos, septate vagina, unruptured hymen, senile endometritis, pyometra, cysts of the vulva, Bartholinitis, caruncles, polypi, sterility, spasmodic dysmenorrhoea, cervical lacerations, hypertrophied clitoris, retained products of conception, and various diagnostic explorations of the uterine cavity. There was no death after any of the 839 vaginal operations; which, added to the 545 abdominal sections, give the total of 1,354 consecutive operations in 1919, 1920, and 1921.

SOME COMMON DEFECTS OF DIET AND THEIR PATHOLOGICAL SIGNIFICANCE.

ABSTRACT OF THE OLIVER-SHARPEY LECTURES DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS,

BY

E. MELLANBY, M.D.,

PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF SHEFFIELD.

LECTURE II.

In his second Oliver-Sharpey lecture, delivered on May 4th; Professor E. Mellanby began by reminding his audience of the conclusions to which his first lecture had pointed. He had stated that foodstuffs could be divided into two groups. The larger group, which included the major part of the average diet, was practically devoid of sodium, calcium, chlorine, and two vitamins—namely, the fat-soluble A and the antiscorbutic factor. The reason why this was the general diet was because modern urban communities lived at a distance from the areas where food was produced, and therefore preference had to be given to foods for popular consumption which were easily transportable and which had good keeping properties. The economic situation made it necessary also that foods should be cheap and abundantly produced. He had also pointed out that taste was an uncertain factor in deciding the relative value of foods, and did not prevent people from eating the wrong thing. Certain foods which seemed to be good, such as cereals, upon which children flourished and grew fat, might, under certain conditions of ill balance in other respects, give a deceptive impression of being more nutritious and satisfying than they really were. He had then proceeded to consider, what would be the main theme of this second lecture, the factors in diet which were responsible for the calcification of teeth and bones.

Professor Mellanby went on to say that in all his investigations upon deficiency diseases he had been impressed by the fact that as soon as there was any interference with a natural food product it became less suitable for food and lost some of its best properties. He took as an example the case of milk: if milk was allowed to go sour and acid caseinogen to be precipitated the calcium was lost, so that acid caseinogen used in a diet already deficient in fat-soluble vitamin made the resulting rickets much worse.

Calcium and Fats.

Even if butter were added to a diet a certain additional quantity of calcium must be added to obtain the maximum physiological value. Butter was less satisfactory from the point of view of rickets prevention than the milk from which the butter was made, probably because, in the course of separation, the substance lost some of its calcium. Butter therefore was not as good a food as one would expect, and the results could not be improved in the case of an ill-balanced diet by giving larger and larger quantities of butter. The more butter that was given the worse under these circumstances did the animal become, and the animal might be made very ill by being given much butter without a certain amount of calcium to balance the diet.

This fact had been worked out by McCollum, of Johns Hopkins University, who had tested on rats the value of a diet as affecting growth, fertility, and the power of the mother to rear her offspring. McCollum had shown that the conditions could not be made better merely by increasing the fat. He had added first of all a mere trace (0.1 per cent.) of calcium carbonate, and the rats did better in growth, though the second generation of young rats did not thrive at all. But on doubling the percentage of calcium carbonate, not only was the growth of the adult rats much improved, but the second generation also began to flourish. Cod-liver oil had the power of utilizing to the full every bit of calcium present in the diet, and with 2 per cent. of cod-liver oil added to a diet in which there was 0.1 per cent. of calcium carbonate the condition of the animal was much better than with 8, 10, or even 20 per cent. of butter, with the same minimum of calcium, and no cod-liver oil. If, however, the amount of calcium was raised to 0.5 per cent. butter under those conditions became as good as cod-liver oil. The cod-liver oil could use the minutest quantities of calcium, which the butter could not. McCollum's explanation of these facts was rather hesitating, but the simplest view to take was that cod-liver oil contained a large amount of the fat-soluble vitamin and butter only a small amount.

The lecturer then passed on to speak of the work of Zilva and Miura in the biochemical department of the Lister

Institute. Their growth experiments depended on a piece of technique which seemed to him to be extremely able. They fed young rats on a diet which was so devoid of fat-soluble vitamin that the animals ceased to grow, and their weight remained stationary. Then to this diet were added the substances whose action was to be tested. If the interpretation of these experiments was correct, it looked as if there was a great deal more of this vitamin in cod-liver oil than in butter. In any case, taking these facts together, it was evident that butter was inferior to milk, and one explanation at least was that in milk there was a larger quantity of calcium, which was lost on the separation into butter. One result of feeding animals on butter was to give a beautiful glossy skin; but, although there was no eye disease—keratomalacia or xerophthalmia—which occurred with other diets, there was still rickets with a butter diet if calcium was not ensured in sufficient quantity.

Iodine Deficiency.

There was one point to be made in connexion with the constitution of cod-liver oil. Cod-liver oil did contain, at any rate, one substance which was not possessed by the other fats. In the animals on which the experiments had been made it had always been possible to detect which animals had had cod-liver oil by examining their thyroids. The cod-liver oil always ensured thyroids normal in size, whereas the thyroids of animals on other fats in these deficiency experiments tended to enlarge. In twelve puppies in whose diet cod-liver oil was used as the fat the average weight of the thyroids was 0.58 gram, while in twelve puppies fed on butter instead of cod-liver oil the average weight was 2.77 grams. Not only was there this difference in the weight of the thyroid, but the epithelium became more of a columnar nature and there were irregularities and invaginations of the epithelium and general abnormality in the thyroids of the butter-fed puppies. The hyperplasia produced in the gland by these means was almost indistinguishable from that associated with exophthalmic goitre, although there were none of the symptoms of this condition. The simplest explanation of the difference between the glands in these two types of animals was that cod-liver oil contained a certain amount of iodine, and the other fats did not contain iodine. It was instantly appreciable from a study of these dietaries how many substances in the ordinary range of foodstuffs did not contain iodine, for these animals were fed on quite a variety of food.

It was probable that a deficiency of iodine in human diet caused abnormalities, though he did not think such iodine deficiency very common in this country. In any event the ordinary case of goitre could hardly be said to be due entirely to deficiency of iodine in the diet; it was no doubt partly due to this cause, but it was due to some other lack of balance as well, making the story altogether a complicated one. In America the prophylactic treatment of enlarged glands was pursued by giving school children small doses of iodine twice a year, and it was said that where this procedure was adopted there was no subsequent enlargement of the gland. In any case in these animal experiments cod-liver oil prevented any of this kind of hyperplasia. However the animals were fed, and whatever the other conditions, if they had got cod-liver oil in the diet they always retained a normal gland. The action of cod-liver oil could not be explained merely on the ground of the iodine content; there must be other things in addition. If small quantities of iodine were given to patients suffering from exophthalmic goitre—say one or two grains three times a day—the effect was quite dramatic. Usually this treatment for a time altered completely the metabolism of the patient. The patient put on weight, the tremor disappeared, sweating gave place to coolness, excitability to quietness, and with all this the swelling at the neck became larger. These were the

In 200 cases the administration. If cod-liver oil were given, tumour proved to be exophthalmic goitre the effect was to increase the size of the gland, and the size of the gland usually increased; while in the other cases the effect was different from the iodine cases. Nine of the cases in that he was discussing this matter many of them were degenerated from the curative point of view. One patient having general myoma was removed by the abdominal route, the abdomen was opened, and the tumour was removed. Professor Mellanby pointed out that in 99 cases of hysterectomy his first lecture he had pointed out that in 180 cases of hysterectomy 180 times, myoma affected by rickets the growths could not grow, and in 100 cases there were six deaths: more cereals eaten, every-thing the rickets produced in

the absence of the vitamin. When these results were first published he thought that the cause of this was the amount of carbohydrates which the animals had eaten, but lately he had taken up the subject again to see whether there was any difference between the cereals, independently of their carbohydrate content, and he found that there was such a difference. A dog was placed on a standard diet, with olive oil as a fat, and white flour. He had been inclined to predict that oatmeal and wholemeal flour would be the best cereals because these contained calcium, and that white flour, having lost its calcium, would be the worst. But the dog which had had white flour as its cereal appeared to be fairly normal, whereas the dog which had had oatmeal got rickets. Therefore from this point of view oatmeal was worse than white flour. The x-ray photographs showed that the animal fed on white flour had a certain slight amount of rickets, whereas an animal fed on wholemeal flour had more pronounced rickets, everything else in the diet being equal; with rice, again, there was less rickets, and with oatmeal more. These results were entirely opposed to all that one would imagine. A dog brought up on polished rice plus wheat germ showed worse rickets than a dog brought up on rice alone without the wheat germ. He could not see the explanation at present. It did not mean, of course, that oatmeal and wholemeal flour were worse than rice and white bread, but what could be said was that when a diet was deficient in fat-soluble vitamin, oatmeal and wholemeal flour seemed to be the worst cereals from the point of view of continuing rickets.

Diet in Human Rickets.

Turning to human rickets and the applications of these results to the treatment of children, the lecturer said that obviously the matter was most important from the point of view of infant health. If the process of calcification of teeth and bones were well started at an early age, it was difficult to upset the process later on. In Sheffield, where he had been working lately, there was a great deal of child rickets of a much worse type than anything seen in London, and there was much adult rickets also. In the treatment of these children the diet on which they were put did not differ greatly from normal. It contained milk, bread, and beef dripping. The children were given about one ounce of minced raw meat, with potatoes and greens, and milk pudding; and in addition to these ordinary things he gave them cod-liver oil three times a day, and always included an orange in the diet. Cod-liver oil, however, had its dangers—for instance, it sometimes led to dyspepsia—and if there was any difficulty about giving it, the best plan was to cut down the other fats. On these diets the rickets was cured. He showed some striking comparative photographs of children who came in with bad deformity and gradually improved under this diet. Some of the children with rickets were quite unable to stand when they came in, and often appeared quite imbecile. The diet not only cured the rickets and strengthened the bones, but absolutely transformed the child's attitude towards life. He did not understand the talk about the necessity for exercise and massage and electricity in rickets; it was the deficient diet which prevented exercise, and until that was rectified the rickets would go on.

In conclusion Professor Mellanby said that he had used this question of rickets and the calcification of bones, not in order to show the etiology of the disease or even the treatment—he had used these facts to illustrate the differences that could be brought about in the anatomy and physiology of ordinary human tissue by changes in diet. It was possible now to take a point of view which would have been quite out of the question a few years ago. This work on foodstuffs was only at its beginning, and it would take many years before all the variables could be worked out. These diets did not only produce bone changes; paralytic effects and other nervous symptoms were produced, and often in these animals changes were brought about in the heart which made them extremely susceptible to anaesthetics. Under the influence of diet they became also very susceptible to catarrhal infections of the alimentary canal and the respiratory tract, and to skin affections; but these conditions had not been worked out because it was not known in detail what were the actual factors involved. Although it was impossible to demonstrate at present the basis of the susceptibility to these infections, he had no doubt in his own mind that deficiency of diet played a large part in them. In any case in this kind of work the laboratory justified itself in a manner in which perhaps it had never done previously.

THE INTERSTITIAL GLAND.*

BY
LEONARD WILLIAMS, M.D.,
LONDON.

It has long been known that the reproductive glands both in man and woman preside over the determination of what are called the secondary sexual characteristics. The primary sexual characteristics are, of course, penis and scrotum in the male, and vagina and uterus in the female. Among the secondary sex characteristics are the beard and the bass voice in the male, and in the female the smooth skin, the treble voice, and the development of the mammary glands. There are other physical differences between the two, such as stature and breadth of pelvis, and these are accompanied by certain mental and temperamental differences upon which I need not insist. Ever since castration was first performed—and castration is probably the oldest of all surgical operations—it has been evident even to superficial observers that castrates differed in several very important particulars from those who had not been subjected to this mutilation. It has thus become a matter of common knowledge that the testes in the male and the ovaries in the female supplied some element to the economy which not only determined, but served to maintain, what we call maleness in the one and femaleness in the other. In the case of man it was believed until comparatively recently that this element or essence was derived from the tubuli seminiferi, and to some extent perhaps from the prostate gland. This, though a very natural inference, has proved to be erroneous. It has now been shown beyond any manner of doubt that this essence or hormone is secreted by what is known as the interstitial gland.

The interstitial gland was first described by Leydig of Frankfurt in 1850, who wrote as follows:

"Comparative histology has shown that in addition to the seminal tubules, blood vessels, and nerves, the mammalian testicle contains another constant structure, which appears as a group of cells which, when small in number, seem to follow the course of the blood vessels, but when plentiful seem completely to surround the seminal vesicles as though to embed the latter."

This observation of Leydig's, if at the time of its publication it was noticed at all, was regarded merely as an histological curiosity entirely devoid of physiological significance, and no reference appears to have been made to it until 1903, when Ancel and Bouin published the first of their series of papers which have since become classical. It is interesting to note that about the time of Leydig's observation, Claude Bernard was delivering at the College of France a series of lectures on experimental physiology in which he coined the term "internal secretion." It was many years later that his co-worker Brown-Séquard, after experiments on himself, scandalized London and even Paris by proclaiming that he could cure sexual senility by injections of fresh testicular extract. As we shall see presently, he was much nearer the truth than his contemporaries imagined.

Such, then, is the now famous interstitial gland—a mass of minute structures not unlike fatty globules situated in the connective tissue of the testicle, separate from and unconnected with the vesiculæ seminales and vas deferens, and endowed with the function of supplying an internal secretion to the economy which determines and maintains not only the secondary sexual characteristics, but also the copulative capacity of the individual. So far, I have dealt only with the testicle. The ovary also contains an interstitial gland, but as the presence in the adolescent and adult ovary of the corpus luteum produces a complication which renders the train of events rather difficult of clear comprehension, I shall not attempt to deal with it here. In elucidation, however, of some points of considerable importance I must briefly consider the question of the development of the interstitial glands in the two sexes. At the moment of conception two elements, a male and a female, combine to form an entity. These elements are warring elements, each of them potentially charged with their characteristic interstitial glands, which develop very early in embryonic life. For several weeks this embryo is neuter, and we are to suppose that the male element and the female contained therein are striving for mastery the one over the other. Then comes the time when one, say the male, has definitely gained the victory, so that penis and scrotum instead of vagina and uterus result. But the victory is never complete. The embryonic inter-

stitial glands on both sides have been mobilized, the armies have been engaged, and albeit the one may win, the other, though defeated, is by no means annihilated. Thus it comes about that in every child born there remain a certain number of these antagonistic interstitial gland cells which, entrenched opposite their victors, continue to glower at them, spoiling for the next encounter. The two armies now cease firing and go into winter quarters. Then at the age of puberty there ensues a second battle royal. The fact that the external evidences of maleness are firmly entrenched does not prevent the female interstitial cells from making one last desperate attempt to gain the mastery; so that side by side with the secondary male characteristics which should accompany the penis and scrotum there may appear some secondary female characteristics, such as a broad pelvis, high-pitched voice, together with female mentality and feminine tastes. There is no man but has some taint of the woman in him, and no woman without some smatch of the male. When the victory in favour of maleness is complete the result is a Caesar, a Napoleon, a Bismarck—active, resolute, and ruthless. When less complete you have the ordinary man, respectable, hard-working, but with engaging weaknesses. With yet another dose of the female interstitial gland in his composition you come upon the effeminate artistic male, who, whatever his practices, is usually homosexual at heart. Reverse the medal, and you are in the presence of such an eternal femininity as Josephine or Mary Queen of Scots. With added male elements, in different degrees, you see Queen Elizabeth, Catherine of Russia, Madame de Staël, or the latter-day suffragette. It is more than probable that among the ranks of the last were a large proportion of women in whom the male and female elements were so nicely balanced as to render them frankly homosexual, and that their activities were directed, subconsciously perhaps, to obtain, not so much a vote, as the right to dispute on equal terms with their male adversaries in the gate of the forum and the market place. "Infirm of purpose," you can hear them shout with Lady Macbeth, "infirm of purpose, give me the daggers." The lineal representatives of these portents of a generation ago are now engaged, some of them, in the exercise of what they are pleased to call "self-expression" in journals and novelettes. And someone recently compared their methods to those of the little boy, newly awakened to the stirring of sex within him, who writes obscene words on the vicar's garden gate.

From these considerations two points of social importance emerge. One is the question of the determination of sex in a young embryo; the other is the attitude which a civilized community should adopt towards homosexuality. Taking the latter point first and briefly, I am entirely of the opinion, suggested rather than expressed in a recent lecture by my friend Julian Huxley—namely, that the present law on the subject requires revision. Regarded in the light of pure physiology, it is no more reasonable to punish a man for being homosexual than it would be to punish him for having red hair. Both of these things are burdens cast upon him by forces over which he has no sort of control, nor can he alter or even modify them by any effort of the will. It is high time that the members of our profession expressed strong and clear views on this question. Let us remember that it is not so very long ago that people were tortured for being insane, and that it was a great-hearted French physician, Philippe Pinel, who died in 1826, who, at the risk of his own life and liberty, insisted upon the humane reforms which were afterwards generally adopted.

On the second point, the question of the artificial determination of sex soon after conception, though the present state of our knowledge does not permit of dogmatism, I should like to say that if the train of events which I have sketched above is even approximately correct it is reasonable to suppose that by reinforcing the male element in the embryo by male interstitial gland, administered to the mother, we ought to be able to determine the victory in favour of definite maleness in the full-time child, and that by exhibiting the same extract when puberty threatens we could ensure against anything in the nature of homosexuality in the adult.

But things are not always what they seem, and this is even more abundantly true in the domain of the ductless glands than elsewhere. These glands constitute a hierarchy of interdependent entities. I am fond of comparing them to the eight rowers in an outrigger boat. All are pulling in the same direction, and yet some of them antagonize certain others. If you reinforce one his antagonist will immediately be stimulated to retort, so that unless you have experience to guide you, especially in the dose of the original reinforcement,

* A paper read before the annual meeting of the Westminster Division of the British Medical Association.

you may bring about a result which is the exact reverse of what you desire. I am nevertheless of opinion that in a proper dosage of the appropriate interstitial gland we hold the key to the solution of the vexed and much-debated question of the artificial determination of sex.

Let us now return for a moment to the mammalian testicle. We have seen that it has two sets of glands—the tubuli seminiferi and the interstitial glands. The former of these supplies an external secretion which is conducted by the vas deferens to the vesiculæ seminales, where it is stored for emergencies. The second, the interstitial gland, is a ductless gland which pours its secretion directly into the blood vessels to act as a hormone—that is, as a specific stimulant to certain parts of the economy. Now, the interesting point about these two activities is that they are in some senses antagonistic. Let me say, parenthetically, that the more you study the endocrine glands, the more deeply do you become impressed by this element of strife within the body. There is war between the male elements and the female in the product of conception; there is war between the thyroid and the pancreas; there is an armed neutrality between the thyroid and suprarenal; it is pull devil, pull baker, between the pituitary and the gonads; and here in a single structure, the testicle, we find, where we should least expect it, a never-ending combat between its internal secretion on the one hand, and its external on the other. The bone of contention seems to be the lion's share of the blood supply. Both the external and the internal appear to demand more than the other, for it has been shown that when one is down and out the other multiplies abundantly.

In 1903 Ancel and Bouin described some of the effects of ligaturing the vas deferens on one side in dogs. This experiment has been frequently repeated, and the result has always been a gradual atrophy of the seminal vesicles on the side of the ligature. Recently, however, another result has been observed—namely, that *pari passu* with the atrophy of the seminal vesicles there has appeared a definite hypertrophy of the interstitial element. The knowledge thus obtained has been applied clinically to prevent or counteract the degenerative effects of sculity. In America very largely, to some extent both in France and Austria, though, so far as I know, not yet in this country, the operation of ligaturing the vas deferens on one side has been performed in elderly men, and has been followed by a remarkable access of mental and physical vigour. As to how long the rejuvenescence thus produced may be expected to last there do not seem at present to be any data upon which to form an opinion. Brown Séguar's successful experiments on himself were similar to, though by no means identical with, those which are now being performed; but if his case is to be accepted as any guide we must not place too much reliance upon these methods of defying time, for he was no more than 77 when he died.

Soon after the x rays were introduced it was found that many very serious penalties attached to the pioneers in this fascinating means of diagnosis and treatment. Among the less serious drawbacks to constant exposure to these rays it was found that the operators became sterile. They did not lose their sexual capacity or their sexual appetite, but they became incapable of begetting children. In 1905 Bergonié and Tribondeau showed that the effect of the rays was to cause atrophy of the seminal vesicles and concomitant hypertrophy of the interstitial glands—the same result; in fact, as is now known to be produced by ligature of the vas deferens. It therefore comes to this: an elderly man who wishes to renew his youth need not subject himself to the operation of ligature of one vas deferens so long as he can find a radiologist who can expose one testicle, and one only, to the activities of the x rays for a period sufficiently long and in a dose sufficiently powerful to ensure the atrophy of the seminal vesicles on that side. The interstitial glands will then hypertrophy and fructify, with results which may or may not be altogether desirable even to the individual. On that point there is only Faust to interrogate, and he is silent.

There are some other influences of what may be called a more normal kind than the foregoing, which seem to give rise to results somewhat analogous. Chief among these are the poisons of alcohol and tuberculosis. It is a common observation that alcoholic drinks produce an aphrodisiac effect upon some people. The porter in *Macbeth* informs us that "drink is a prevaricator with lechery; it creates the desire and takes away the performance"; the physiological

meaning of which is that while stimulating the interstitial gland, it paralyzes the sphincters of the veins in the corpora cavernosa. That chronic alcoholism leads to an hypertrophy of the interstitial element in the human testicle is now a recognized fact; that it leads to a concomitant inactivity of the seminal vesicles is a reasonable deduction from many of the confidences, some of them embarrassing, which we receive in the consulting room. In the matter of tubercle, it has long been recognized in France that a very early manifestation of the disease is a heightening of the sexual appetite. In this country the matter is, of course, regarded from the opposite point of view, the pulmonary phthisis, when it appears, being confidently ascribed to the direct intervention of the Almighty for the punishment of the premonitory sexual excess. Wherever the truth may lie, all the authorities who have written on the subject agree that after death from pulmonary tuberculosis the interstitial glands are found to be much hypertrophied.

I have already said that the interstitial gland is a member of the hierarchy of glands of internal secretion known as the endocrine system. To endeavour to think in terms of this system is to understand the fascination of the will-o'-the-wisp and its elusiveness. I try, as I have said, to think of it as a trim and true outrigged boat, manned by trained men and wisely guided by a cox, but ever and anon in sheer desperation I cry aloud that it is naught but a cage full of wild and ineffectual monkeys. To try and establish any constant rule or relationship between the component glands is deeply to sympathize with Sisyphus, or rather Balbus, for just when you think to have built your wall the whole bag of tricks comes tumbling about your toes. It is therefore in a chastened mood that I venture to suggest—I would not dare to dogmatize—some of the relationships which the interstitial gland appears to have with some other members of the hierarchy. First, then, there is the suprarenal, which appears to be a predominantly male gland. Its cortex seems to supply a combative element to the character, and when the whole gland is well developed and active, the stature is medium or short, the trunk is hirsute, and the individual is normally or even abnormally sexually inclined. There is here some very obvious association between the interstitial gland and the adrenal, but the exact nature of that association remains to be explained. Then there is the thyroid, a predominantly female gland, which is nevertheless not only the great stimulator of metabolism in general, but seems to exercise a particular effect upon the sex glands in the male, inasmuch as when orally administered, the extract will cause the descent of a hidden testicle in young adults. And again there is the pituitary, which presides over the type of the bony skeleton, and is therefore presumably under the direction of the appropriate interstitial gland, male or female; as the case may be. And yet it seems to have a peculiarly intimate connexion with the ovary, for ordinary amenorrhœa is more surely and more swiftly cured by oral exhibition of its extract than by all the curative and curative ministrations of the operating gynaecologist. Nor need I remind you that Fröhlich's syndrome as it is called, dystrophia adiposogenitalis—or, as Jonathan Hutchinson, who was the first to describe it, originally christened it, lipomatosis universalis asexualis—proclaims a direct and intimate relation between the pituitary and the interstitial glands in the male, for the dystrophy is simply, surely, and swiftly cured by administration of extract of the whole gland by the mouth. Then there are the glands, notably the thymus and the pineal, which seem in some measure to act as a drag or check upon the activities of the gonads, while there are facts concerning them which point in a direction precisely opposite.

It would be easy to continue thus to pose problems concerning the interdependence of individual glands to which neither I nor anyone else can at present supply satisfactory answers, but to do so would probably serve only to spread my own bewilderment; so I will ask you, for the present at any rate, to join with me in an endeavour to regard these glands, not so much in their individual capacities as in their collective, to look at the boat as a whole, and not at the individual oarsmen.

In the existing state of our knowledge we must be content to treat the endocrine system as a system, and not as an agglomeration of individual glands, so that where there seems to be deficient or superabundant activity in any one gland we must make our therapeutic appeal for regularization to the system at large. That such is the proper course is obvious when we consider that our main enemies are toxins, and that our defences are the ductless glands. If a time should ever

be when we shall be able to allocate to each gland its responsibility for a particular toxin that time is not yet; so that our only rational course is so to husband the resources of the endocrines by protecting them from unnecessary poisons as to keep them fresh and alert to deal with such as are inevitable in our present artificial communal life. If we fail thus to protect them they become prematurely worn out by the ceaseless conflict with poisons which come from without. That is why a gradual decline in vitality so often begins at about 50 years of age, why cancer comes, and arteriosclerosis and other degenerative conditions. The endocrines thus gradually retreating before the advancing toxins are at last driven to capitulate, and the end comes. Now, looking at the matter from the point of view of comparative biology, there is no reason why man should be senile and effete at 70. If we argue from analogy we must admit that in relation to the time which it takes him to arrive at maturity man ought to live to the age of 100 or 120 years. That he does not do so indicates quite clearly that the kind of life he is now leading is not in accordance with physiological laws; that the poisons which he introduces into his system are either too concentrated or too persistently applied for the endocrines to withstand for more than a relatively short period.

It is an interesting fact that the glands in both sexes which show the first signs of fatigue are those which seem to have the closest connexion with the gonads—namely, the suprarenal in man and the thyroid in woman. In woman the reproductive capacity is definitely brought to a close at the menopause, and it does not surprise us that the necessity for redressing the endocrine balance consequent upon the withdrawal of the ovary from practical politics should give rise to considerable constitutional disturbance. It is nevertheless, to me at any rate, rather surprising to find that the gland to which we appeal most effectually in such cases is the thyroid. And here let me say, with all the emphasis at my command, that the appeal to thyroid extract should always be made cautiously at first—that is, with very small doses, never more than 1 grain per diem. I have been preaching this gospel for many years, and, although I am pleased to say I have made many converts, even now scarcely a week passes without my being profoundly shocked by the seemingly light-hearted manner in which members of the profession throw 5-grain tablets at their patients as though they were dealing with confetti at a carnival. That the combative gland, the suprarenal, shows declining vigour as the years advance is a matter of common observation. Bacon tells us that "men of age object too much, consult too long, adventure too little, repent too soon, and seldom drive business home to the full period, but content themselves with a mediocrity of success," which is only another way of saying that the gland of fright and fight has lost its recoil.

It is often said that a train of phenomena takes place in men between 60 and 70 in many ways comparable with the menopause in women. I have never been able to support this view. It is undoubtedly true that in most men the copulative and reproductive capacity begins in that decade sensibly to decline and ultimately to peter out. But by no means in all men. We could all of us cite outstanding instances of men who have retained a large measure of sexual power well into the following decade, but no one except the biographer of Sarah has ever recorded a case of a woman who has reproduced her kind at such an advanced age. There is obviously no reason why a man should lose his copulative and reproductive power so long as his gonads retain their efficiency, and this efficiency usually becomes impaired about the sixties because of the accumulation of poisons in the system. We have already seen that certain poisons (and I have instanced two only among many) cause an atrophy of the seminal tubules and an hypertrophy of the interstitial glands. Now it is more than likely that the interstitial hypertrophy represents an endeavour on the part of these glands to repel a chronic toxæmia. The hypertrophy succeeds for a time in supplying the extra quantity of necessary antidote, but at last, overwhelmed by the strength of the invader, the gland succumbs. We see this train of events so often in the case of the thyroid—the goitrous retin, for example—that it seems reasonable to offer the same explanation in the case of the interstitial gland. Then there is the senile hypertrophy of the closely associated prostate to account for. Is it possible to doubt that this too is an anti-toxic gland, or that its gradual enlargement with advancing years is due to the constant endeavour to prevail in the unequal combat against lethal poisons introduced from without? The removal of the gland—which is, after all,

a simple surgical procedure—has been shown to be followed at no very long intervals by symptoms which go far to support this view.

And so we come to the question as to what are these toxins which the endocrine system is at such pains to neutralize and nullify. The answer is altogether outside the terms of my present reference, but to indicate the sanction for the views which I hold very strongly let me remind you that man is the only animal who has lost the instinct of physiologically selecting his food; that man is the only animal who cooks his food; and that the Almighty no more invented the kitchen than He ordained the gin palace or the opium den. Cooking destroys vitamins, and vitamins are to endocrines what endocrines are to the economy. The kindly fruits of the earth to which we do lip service in the Litany are ruthlessly relegated to a back seat in our everyday lives, and until we see reason in this respect while it is yet day we shall continue to poison our endocrines and to pass ignobly into nothingness with our allotted tasks but partially accomplished.

NOTE ON THE PEPTONE TREATMENT.

BY

A. G. AULD, M.D., D.P.H. Oxon.
(F.R. in University College, London.)

Is the use of peptone for certain cases of asthma and other conditions of sensitization we have, as a rule, to rely on commercial products. These differ widely in composition, and consequently in their pharmacological actions. The latter are at present undergoing investigation, and some very divergent preliminary results have been obtained by Professor A. J. Clark with some samples submitted to him. What is really needed are preparations physiologically standardized. The proteoses are by far the most important constituents. A peptone solution fit for clinical use may be roughly tested by adding to a few cubic centimetres in a test tube two or three drops of strong nitric acid. A copious white precipitate is immediately produced, consisting of primary proteoses. On heating, the precipitate entirely dissolves, and reappears on cooling.

In a former paper¹ it was stated that Witte's peptone, even in the small doses of the 2 per cent. solution, may produce an immediate sharp reaction in certain subjects. Flushing, salivation, headache, palpitation, cyanosis, and dyspnoea are the usual symptoms. The dyspnoea is asthmatic in character, and may last a considerable time. Faintness, sickness or vomiting, purgation, and localized oedema or urticaria may supervene in very sensitive subjects. In the mildest cases flushing, alone or with a sense of constriction in the chest, occurs. Any combination, however, may be encountered. There seems to be no doubt that this almost instantaneous and sometimes alarming syndrome is caused by histamine in the peptone. The above symptoms can be faithfully reproduced when histamine is administered intravenously, and are due to a sudden injurious dilatation of the capillaries and venules, peripherally induced, together with stimulation of smooth muscle. Haake and Koessler,² by an ingenious and exhaustive process, though finding no histamine in blood, fresh tissues, casein, etc., as originally affirmed by Abel and Knab, nevertheless recovered it from Witte's peptone in the proportion of 0.00335 gram to 100 grams peptone. It might be urged that this represents too small a quantity in the intravenous injections to be effective, and that the symptoms must be referable to the peptone itself. Now these figures give 1/1500 mg. histamine (the equivalent of 0.3 c.c.m. of a 1 in 500,000 aqueous dilution) in about 1 c.c.m. of a 2 per cent. solution of Witte's peptone (an average dose). This dilution, I found, gave a positive dermal reaction (0.5 cm. and over) in many subjects, but the intravenous injection of 0.3 c.c.m. in the subjects tested was either very slight in effect or negative. However, when this amount was mixed with the usual doses of a histamine-free peptone, the injections, previously negative, gave the histamine effect in numerous instances. Apparently, therefore, the peptone reinforces in some manner the action of the histamine. The intensity of the effect depends on the amount of histamine-peptone present in the blood per unit of time—in other words, on the rapidity of the injection. The reaction in the peptone (protease) itself, should it occur, requires some time and is pyrexial in character.

It is necessary to recognize that histamine is a degradation product (by decarboxylation) of the amino-acid histidine, and acts after the manner of a powerful drug. Its presence in a peptone is a drawback, as it not only may entail a limitation of the dosage, but is itself quite useless in the immunizing process, if not actually harmful. It was found by Hanke and Koessler that peptone which was perfectly histamine-free produced the typical peptone shock. Histamine shock has indeed the more obvious features of peptone shock, but is shorn of certain essential attributes of the latter—namely, extensive katabolism of body tissues and incoagulability of the blood (supposed due to antithrombin formation from the interaction of peptone and hepatic cells).² Ringer and Underhill³ were unable to produce any increase in tissue katabolism by shock doses of histamine enormously greater than those contained in a toxic dose of Witte's peptone. Further, histamine is unable to produce swelling of the liver in dogs, or to produce pyrexia, or to desensitize. Histamine has been occasionally detected in the intestines, but whether it escapes the action of the liver and produces the symptoms of disease is an open question. It certainly can be swallowed in considerable amount, comparatively speaking, without the production of any symptoms. But in the katabolism of tissue associated with anaphylactic or anaphylactoid shock it is quite possible that histamine may be produced where cell-oxidation ceases, just as it is supposed to be formed in the tissue destruction leading to wound shock.

The dermal (scratch) test may give evidence as to the presence of histamine in a peptone (conc. solution), as all individuals give a marked though varied response to extremely dilute solutions of histamine. For testing purposes one of Burroughs, Wellcome and Co.'s ergamine tabloids may be dissolved in water or saline in various dilutions and used as a control. A peptone giving a wheal of 0.4 cm. and upwards in diameter in a series of cases may be suspected, the size of the wheal depending on the sensitiveness of the patient to histamine, though it must be remembered that sensitiveness to the peptone itself may also be present. Of the peptones I have tested in this way, the largest wheal (up to 1 cm.) has been constantly given by Parke, Davis's peptone (which contains no primary proteose). Confirmatory evidence is afforded in the immediate histamine effect produced by the intravenous injection of very small doses of this preparation.

A patient may be hypersensitive to both peptone and histamine, but the same patient may react differently to histamine on separate occasions, owing to unknown causes; also, the dermal and constitutional reactions do not always correspond. Sometimes intradermal tests are made, but they are usually unnecessary and may be dangerous, unless a very dilute (2 per cent.) solution of the peptone or suspected peptone be used, and then only 0.1 c.cm. should be injected. The injection of a strong solution may cause histamine shock. Also, if after a negative intradermal injection the ordinary intravenous injection be soon made, the two may summate and cause shock. According to Dr. Chandler Walker,⁴ intradermal injections are very erratic, far too sensitive, and practically non-specific.

Ordinarily, therefore, and especially for those requiring a higher dose of proteose—sufficient, that is, to produce a slight constitutional reaction—the Armour No. 2 peptone† should be employed, which, in my experience, never gives the histamine effect. It will be found that the maximum dosage will approximate 2 to 2.5 c.cm. of the 5 per cent. solution. Witte's peptone is of particular value in certain cases owing to the nature of its proteoses, but it is best given diluted with a weaker peptone, as recommended in my last paper.⁵ But the Armour peptone (intramuscular or intravenous) gives the best results in the majority of cases, and may be safely administered to the youngest child. Should toxic symptoms unexpectedly supervene, suspect contamination of the solution—a not infrequent occurrence. It may be added that a satisfactory immunizing process is characterized by a slight leucocytosis, particularly as regards the large mononuclears, and by increase in the haemoglobin and red cells.

A CASE OF NON-RHEUMATIC AORTIC STENOSIS
IN A YOUNG SUBJECT.*

BY

W. GORDON, M.A., M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL;
PHYSICIAN TO THE WEST OF ENGLAND EYE INFIRMARY.

DR. L. GALLIVARDIN has recently described in an interesting paper a group of cases of aortic stenosis in young persons which he believes to be non-rheumatic in origin.¹ The case I bring before you seems to belong to this group.

The special features of the group are:

1. Aortic stenosis with loud murmur and marked thrill in young persons.
2. The stenosis generally "pure"—that is, unaccompanied by regurgitation, or, if aortic regurgitation coexists, its murmur much less marked than the murmur of the stenosis.
3. A long period without symptoms.

The causation Dr. Gallivardin considered doubtful: some cases he thought might be of congenital origin; most, he suggested, might be due to a post-natal valvulitis of unknown nature. Eight male cases were described in his paper, aged respectively 21, 25, 19, 20, 17, 19, 21, and 23. Of these the first only had been also observed at an earlier age—namely, at 7 or 8.

H. C. P., aged 17½, a bricklayer's apprentice, a florid, well-nourished, healthy-looking, intelligent lad, was sent to me by Dr. Whalfe of Heavitree, complaining of shortness of breath on exertion. This had been noticeable for six months, but only troublesome for three months, during which he had been put on a man's job, carrying hods and working eight hours a day. He had had no pain, faintness, giddiness, cough, or blueness on exertion. At 11 years old a school doctor had forbidden him to play football on account of "incurable" heart trouble, but he had continued to play because he felt no ill effects from doing so. The boy has never had rheumatism, chorea, or scarlet fever. No doctor attended his birth. At nearly a year old he was in this hospital for large glands in his neck which subsided without operation; no mention is made in the surgical notes of any tonsillitis, nor, unfortunately, of the state of the heart. As a child he had whooping-cough and chicken-pox. On leaving school he worked first as a compositor, then as an Army Pay Corps messenger, then for sixteen months as a tailor's porter, with much bicycling and some lifting of heavy weights, finally at his present job, which has proved too much for him. He has never had any serious accident or sudden overstrain; influenza in 1918 was the only illness since childhood in which he needed a doctor.

There is no family history of acute rheumatism or chorea. His father is a strong-looking man of 55 who has had some "rheumatic gout" for ten years, never syphilis. His mother died of phthisis at 46; she was subject to "fainting attacks," but was not said to have heart disease; she had no miscarriages. A brother of the patient in the army died of phthisis at 26. Two sisters and another brother are alive and well; the surviving brother has had his tonsils removed, but is stated never to have had acute tonsillitis. The circulatory condition is as follows: Pulse regular (84), not "water-hammer," giving the anacrotic, flat-topped tracing of

aortic stenosis. After brisk exercise the rate rises to 108, but drops back to 84 in two and a half minutes. There is visible pulsation above the manubrium and clavicles, but little further up the neck. In the erect position the heart's apex beat is in the fifth space, half an inch inside the left mammary line, and the dullness reaches transversely from that point to three-quarters of

FIG. 1.—a, a, Limit of thrill in upright position. b, b, Ditto in recumbent position. c, c, Limit of systolic murmur, upright position. x, Maximum point of murmur and thrill.

an inch to the right of the mid-sternal line—practically a normal width. Over the upper part of the chest there is a marked systolic thrill and a loud, rasping systolic murmur; both have their maximum close to the right sterno-clavicular joint and just over the manubrium in the neck; the murmur is heard in the carotids up to the ear, and almost all over the chest. Fig. 1 shows the area

* Read at a meeting of the Exeter Division of the British Medical Association, February 17th, 1922.

of the thrill and the lower limits of the murmur. There is also a much softer, fainter diastolic murmur, whose area is shown in Fig. 2. When I first saw the patient this diastolic murmur was heard with difficulty with the double stethoscope, a little better

FIG. 2.—Area of diastolic murmur, d, d, in upright position; e, e, in recumbent position.

with the straight stethoscope, and surprisingly easily by the ear laid directly on the chest. It is interesting to note that Dr. Gallivardin made the same observation on one of his cases. When a deep breath was taken and held the diastolic murmur disappeared, which I think indicates a very slight degree of regurgitation. The femoral pulses are normal and Durozic's sign is absent. A skiagram shows a fairly normal-sized heart, but with a rather dilated aorta, and with the screen this aorta is seen to pulsate actively—a condition which, Vaquez and Bordet consider, suggests congenital aortic stenosis.³ The second sound is audible over the right clavicle.

There is no clubbing of fingers or toes. The right tonsil is chronically enlarged, a fact of which the patient was unaware. The other organs, including the ocular fundi, are normal.

The diagnosis of an aortic stenosis with regurgitation is here so plain that no discussion is needed. The actual degree of stenosis cannot be great, judging by the pulse, the size of the heart, and the symptoms, although the murmur is what might be suitably called "extravagant." The regurgitation must be very slight, judging by the pulse, the presence of the aortic second sound in the neck over the right clavicle, the size of the heart, the characters of the murmur, and the symptoms. No other cardiac lesion has been detected.

I do not think we can reasonably consider that the valve defect is in this case post-rheumatic. It clearly is not traumatic or syphilitic. So the question to decide becomes, Is the condition of congenital origin, or has it arisen between birth and 11 years of age from some unknown form of valvulitis? I would venture to suggest that it is of congenital origin, and that the whole group, to which it seems to belong, has a similar etiology.

First, clinically when one finds what I have called an "extravagant" murmur with little cardiac enlargement or disturbance, one thinks of congenital heart disease. And this is reasonable, for in such cases an undamaged muscle is driving the blood through sharply defined orifices or against clean-cut obstacles. The stenotic murmur in this group is, in Dr. Gallivardin's words, "intense, rude, râpeux," even "énorme," and is much louder and more widely audible in this boy than in the cases of acquired aortic stenosis of later life to which one is accustomed. The only comparable aortic stenotic murmur I have met with was in another young male of 19, who had recently been passed as a first-class life on account of his healthy appearance and freedom from symptoms.

Secondly, there seems to be a series of similar cases reported in children, and these have been generally diagnosed as congenital. My patient's lesion was detected at 11. One of Dr. Gallivardin's cases was declared to have heart trouble at 7 or 8. MM. Queyrat and Monquin describe an apparently identical condition in a boy 5 years and 8 months old which they call congenital, and in the discussion upon it M. Baré recalled a case observed in a child by himself, and quoted another which had been reported on at 4 years of age.³

Thirdly, lesions capable of causing such signs, though rare, are known to morbid anatomists. Apart from coarctation of the aorta and aortic hyperplasia, which do not concern us here, there are three forms of congenital aortic narrowing—namely, (1) subvalvular aortic stenosis, a few millimetres below the valves, which, unless endocarditis supervenes, allows of survival to adult life with few or no symptoms, but with the physical signs of aortic stenosis; (2) stenosis due to prenatal valvulitis, seldom surviving birth, although, as Hirschfelder suggests, "probably many of the milder cases are escape detection";⁴ and (3) stenosis due to valvular mal-formation, which, if valvulitis does not follow, is compatible with many years of life. Peacock says: "I have seen only two valves at the aortic orifice occasionally in persons who have died in advanced life, and frequently in middle age, without the segments having presented any appearances of more recent disease; and similar facts have been noted by others."⁵ Such a condition (two valves only) would seem capable of accounting for a loud systolic murmur, a retained second sound, and a much slighter diastolic murmur, as in the case before us. It is less easy to imagine the same picture being presented by the result of post-natal valvulitis.

Lastly, although in my case I cannot prove that the lesion is congenital, I can find no history of any condition known to produce valvulitis. The enlarged tonsil might be held to indicate some chronic infection, but we have no evidence that it antedated the murmur. The glands in the neck were probably tuberculous, seeing that his mother and brother died of phthisis. In Dr. Gallivardin's cases I can find no proof that the murmurs described had not dated from birth, and it seems safer to assign a known origin than to invoke an unknown one.

The question is by no means merely academic. If chronic valvulitis is responsible for the condition we must fear its continuance. If a malformation is the cause, provided valvulitis does not supervene, we may hope for many years of life. Although at the moment we cannot come to any final conclusion, it seems worth while raising the point, in order that our congenital aortic stenoses may perhaps be more persistently followed, and that, in the rare opportunities of autopsy, attention may be more closely directed to the possibility of congenital defect.

OBSERVATIONS ON TWO AND A HALF YEARS' ANTENATAL WORK.

BY

MARY E. WESTON, M.B., B.S. LOND.,

ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER,
COUNTY OF LEICESTER.

My object in recording these observations is to show the great value of the antenatal clinic as an educational factor and its possibilities from the point of view of preventive medicine. My remarks are directed to such cases of pregnancy as are commonly classed as normal, for the value of the antenatal clinic in the early diagnosis of gross abnormality has already been sufficiently emphasized in current medical literature. It has been estimated that 40 per cent. of women out-patients suffer from some form of ill health directly or indirectly due to child-bearing. My experience has convinced me that a large part of this ill health is due to neglect of the so-called minor maladies of pregnancy, and that its prevention is largely a matter of patient individual teaching such as can be carried out at antenatal clinics. Of 138 cases 42.8 per cent. suffered from constipation, 36.5 per cent. from flatulence and heartburn, 31.7 per cent. from varicose veins (swelling), and 52.38 per cent. from vomiting. The milder degrees of vomiting were not always entered. Out of 300 mothers whom I personally interrogated, 67, or 22.3 per cent., had never once vomited during pregnancy.

All these women received detailed teaching on hygiene—principally on clothing, diet, and exercise; no medicines were advised except such as can fairly be called "domestic remedies," in order that the antenatal clinic might retain its character as a teaching centre and not encroach in the slightest degree on the province of the general practitioner. Had any case not responded to these simple measures she would have been referred to her own doctor; but out of over 200 cases seen during two and a half years this necessity did not arise, though in some the vomiting was severe enough to interfere with sleep and materially to affect nutrition. In marked numerical contrast to the above figures are the more serious disorders which were treated apart from the clinic and exclusive of venereal disease—namely, there were four cases of contracted pelvis and one of albuminuria.

But apart from improving the health of individual mothers and babies, we are all keenly aware of the need for research in antenatal physiology and pathology. We need statistics on conceptional rate, on intranatal death rate (both foetal and full-term), and on still-birth rate, as well as what has been called intranatal and neonatal death rates. We need, too, both analytical and experimental statistics on the effect of different toxins, x rays, etc., on the germ cell or on the foetus at all stages of its development. Clinics efficiently equipped

338 MAY 27, 1922]

and staffed for such work can be founded and carried on only at great financial cost. Moreover, were such an institution built and endowed in every large town in the country it is only a very small percentage of pregnant women who would see any advantage to themselves in attending, and they very naturally would decline to submit themselves for examination or leave their homes to enter the wards for prolonged observation from altruistic motives. In short, women will never regard themselves or their unborn children as material for research, and the large number of those who are grossly abnormal.

On some such lines as I have maintained almost as easily enough of the

But an educational centre, described as an infant welfare centre, they would serve a useful purpose for collecting valuable figures on many points besides the I have referred to—such, for instance, as the effect of different occupations and of the number and frequency of pregnancy on labour and on lactation, and the relation between various menstrual disorders and fertility. Finally, they would invaluable collecting centres from whence special cases be sent to the larger and more fully equipped clinics.

Memoranda:

and on the trouble they
and in those on whose answers
simple apparatus here described works
adds very little to the weight of the trial frames.
the cylinder while the operator is some distance from
patient, and the adjustment is so fine that this can be done
five times for each division on the scale. It can be fitted to
any trial frame which has a vertical bar for the nose-piece,
and can be attached or removed instantly.

The attachment is on the Bowden wire principle, and
consists essentially of a flexible tube moving through the
centre of a flexible wire formed of a long coil of fine wire.
The latter is shorter than the flex, and this difference
regulates the amount of movement which can be obtained
afterwards. The tube is fastened to the screw of the nose-
piece, from which it takes its fixed point, and its end, near
operator, terminates in a collar which is gripped between
first and second fingers. The near end of the flex is
projecting from the coil by a weak spring, and terminates
in a flat piece to take the pressure of the thumb. The
flex is joined to the clip, which grips the rim of
the other eye.

In subjective testing I use it when the axis has been approximately found, obtained with my present attachment—which is of three-quarters of an inch—is 30 degrees, ample, as it allows for 15 degrees on either side of the mate axis, while at the same time the patient disturbed nor his judgment biased by any manipulation. The movement is smooth, and reversed at any time, simply by releasing the pressure, when the reversing takes place immediately, with no back-lash, such as occurs in rotation of a milled wheel.

It is in retinoscopy, however, that the band of light appears. Here one cylinder is placed with the axis approximately, cylinders are placed with the axis until correction is attained. If now this cylinder and a weaker one substituted. If now this cylinder placed with its axis over the original bright mark will appear to be in exactly the same place as has not been placed exactly over the bright band. For in placing the axis produced a considerable displacement of the bright band. For instance, say, 5 degrees in the axis of this cylinder, say, 90 to 75 or 105. This small displacement of the axis produces a considerable displacement of the bright band. For instance, say, 5 degrees in the axis of this cylinder, say, 90 to 75 or 105. This small displacement of the axis produces a considerable displacement of the bright band. For instance, say, 5 degrees in the axis of this cylinder, say, 90 to 75 or 105. This small displacement of the axis produces a considerable displacement of the bright band.

Late Ophthalmic Surgeon, Expeditionary Force, Aden.

Southampton.

THE CASE OF OSTEITIS DEFORMANS OF THE RIGHT TIBIA, AND
GORDON IN THE JOURNAL OF APRIL 2, 1922.
a patient seen by me about four years ago, with well-marked osteitis deformans of the right tibia, whilst walking on a greasy road. At the time he had a stout stick between his legs, which probably acted as a lever, when picked up he was found to have fractured his right leg. The line of fracture was through the thickness of the head of the tibia just below the tuberosity, and was as horizontal as if it had been done by an osteotome. There was little or no displacement. The leg was put up in a back splint, and after six or seven weeks showed no signs of uniting. It was then put in a Croft plaster splint and massaged, and at the end of six weeks union seemed firm enough to suggest careful trial of the leg. About three weeks later he was showing me what he could do in the way of standing when I heard a loud snap, and it was clear that the union had given way. The leg was again immobilized for several weeks, and as the union still seemed doubtful I asked the late Sir Alfred Pearce Gould to see the patient; he thought that unless union could be induced amputation might be necessary. Meanwhile the leg was put in a calliper splint on the advice of Mr. Gordon Taylor, who said that union in this class of case might take a year and still be possible, and we hoped for the best. Fortunately union did eventually occur, and the man is now going about without apparatus, but with a stiff knee.

The left leg and both forearms were slightly affected by osteitis deformans, but there was no sign of that condition in the skull. There was no history of syphilis. For some years he had suffered from night blindness and retinitis pigmentosa, and most of his life he had had extensive psoriasis, which at one time took on an acute pityriasis form (he had not a square inch of normal skin) and kept him bedridden for about ten weeks. Otherwise he had had no serious illness. Not many cases of osteitis deformans are met with in general practice, but the few I have seen all seemed to have uncommonly hard stout bones—bones which one would never expect to break, and least of all through the thickest part. I suppose the pathological condition of the bone explains the delayed union in my case, but for the comfort of anyone else who happens to have to deal with such a case and gets despondent over the long delay, it seems worth while to report mine.

J. ANDERSON SMITH, M.D.
Bromdesbury, N.W.

THE JOURNAL OF TERMINAL PHALANX OF FINGER.
The JOURNAL of January 21st, 1922, which contains a memorandum (p. 101) by Dr. J. Anderson Smith, M.D., on the terminal phalanx of the finger, and any previous articles on the subject.

has just read the case of J. N. Laird on the subject of a finger. As he states that description of such a condition, I feel record my own case.

In 1915, while effecting a tackle at Rugby football, I sustained a sudden and painful injury to my left middle finger, which became swollen and painful in the region of the distal interphalangeal joint. As I thought that only the soft tissues had sustained trauma, I took little notice of it, and, in fact, played golf the next day. Finding there was little improvement at the end of a week I had a skiagram taken and the condition shown was almost precisely similar to that described by Dr. Laird, the only difference larger.

Treatment, as advised by Mr. Harold Wilson, consisted in wearing for three weeks a glove on the palmar aspect of which was sewn a narrow piece of cane running from the tip of the middle finger to near the wrist, an effective splint being thus formed. Save for a slight overgrowth of callus and a very little loss of flexion at the joint concerned the result was perfect.

HAEMORRHAGIC COLITIS.

HAVING read with interest the recent communications on the subject of haemorrhagic colitis I should like to emphasize the importance of sigmoidoscopy in the diagnosis of such conditions. In true haemorrhagic colitis lesions in the pelvic colon can be demonstrated by means of the sigmoidoscope, and the rectum itself may or may not be affected. On the other hand, the patient may have the symptoms of haemorrhagic colitis and yet the sigmoidoscopy may reveal a lesion confined to the rectal mucous membrane, that of the pelvic colon being unaffected, the condition being essentially "haemorrhagic proctitis." The treatment of these two conditions differs in some respects: haemorrhagic colitis usually requires appendicostomy with irrigation of the colon, whereas haemorrhagic proctitis may be successfully treated by local irrigation of the rectum. In both varieties I have found a course of zinc oxide given internally useful as an intestinal astringent. To illustrate these two varieties I may mention the following cases, which came under my care in the out-patients' department at St. Mark's Hospital.

CASE I.—Haemorrhagic Colitis.

Female, aged 25. History of passing large quantities of blood with mucus and pus from the rectum for two months. The patient was anaemic. Tenderness was present along the line of the colon, especially in the left iliac and pelvic regions.

Sigmoidoscopy showed oedema of the mucous membrane of the pelvic colon, which was very vascular and bled profusely. Sloughs were present on the mucous membrane. The rectal mucous membrane was only affected to a very slight degree. Numerous cocci, chiefly streptococci, were present in the faeces.

The patient was admitted to hospital, and appendicostomy was performed. There was severe haemorrhage from the bowel both before and for a few days after the operation. The bowel was irrigated daily with a solution of hazeline (2 drachms to the pint). A course of autogenous vaccine, prepared from the faeces, was given, and later on a course of zinc oxide when the acute symptoms had subsided, but small quantities of blood and mucus were still being passed. The patient has been under observation since leaving hospital, and at the present time (some twelve months after operation) she is in good health and only passes a small amount of mucus occasionally.

CASE II.—Haemorrhagic Proctitis.

Female, aged 31. History of passing blood and mucus sixteen months previously. This attack subsided, but severe symptoms recurred after an attack of influenza.

Sigmoidoscopy revealed a swollen, very vascular and granular condition of the rectal mucous membrane. The lesion was entirely confined to the rectum, the mucous membrane of the pelvic colon being normal in appearance. The case responded to treatment by daily rectal irrigation with flavine (1 in 1,000), and a course of zinc oxide given internally.

LIONEL E. C. NORBURY, F.R.C.S.,

Assistant Surgeon, St. Mark's Hospital for Diseases of the Rectum, etc.

ELEPHANTIASIS OF THE LABIUM.

The following case is reported for the reason that elephantiasis of the labium is rare in Siam, a country where filarial infection is common and elephantoid complications not infrequent. It is the first case I have observed during several years' tropical experience. Another interesting feature in connexion with this case was the presence at all times of microfilaria in the peripheral circulation. This observation is not in accord with that of other tropical workers (Manson, Stitt, Bahr), who state that sufferers from elephantiasis fail to show larvae in the peripheral circulation.

The patient, a Eurasian woman about 20 years old, had first noticed six months previously a small swelling on the left labium majora that gradually increased in size. She came under observation for the first time early in July, complaining of great discomfort in walking, but had had no pain and absolutely refused operation. She at that time registered a daily temperature ranging from 99° to 101° F. Careful blood examination failed to reveal a malarial infection and a diagnosis of filarial fever was made.

The patient refused all treatment until about a month later she again came under observation complaining of acute pain in the affected part. The tumour mass was found to have greatly increased in size, and was beginning to ulcerate at the base. This time the patient consented to operation, the result being quite satisfactory, even to the complete disappearance of the abnormal temperature, although microfilaria can at this time still be demonstrated in the general blood stream.

The tumour weighed 7 lb., and on section consisted of a thick mass of yellow fatty substance that poured forth large amounts of lymph. Thick fibrous strands divided the mass into many sections that contained dilated and greatly thickened blood vessels.

Reports of Societies.

RECTO-VAGINAL ADENOMYOMA.

A MEETING of the North of England Obstetrical and Gynaecological Society was held in Manchester on May 5th, with the President, Mr. H. CLIFFORD, in the chair.

Dr. A. DONALD (Manchester) read a short paper on adenomyoma of the recto-vaginal space associated with cystic ovarian tumours with tarry or chocolate contents. He reported five cases of recto-vaginal adenomyoma on which he had operated within a period of twelve weeks. In three cases panhysterectomy had been performed, in one double salpingo-oophorectomy with removal of a nodule from the posterior aspect of the cervix, and in the remaining case removal of a hard growth from the anterior wall of the rectum after separation of adhesions. In three of the five cases the ovaries contained cysts with tarry or chocolate-coloured fluid. For some years he had been puzzled by these cysts and had gradually formed the opinion on clinical grounds that they were not due merely to an accidental effusion of blood into a cyst, but were really adenomyomata of the ovary. His reasons for this opinion were as follows: the cysts were generally adherent and in many cases had to be dug out of the back of the broad ligament or the side and back of the pelvic cavity; they had the faculty of burrowing into tissues and of contracting very firm adhesions; the contents resembled exactly the thick tenacious brown fluid that was found in haematocolpos and haematometra and in smaller quantities in the gland spaces of adenomyomata; and there was always acute dysmenorrhoea during the first two days of menstruation. He was anxious to have this theory confirmed by the pathologists, but so far from the specimens he had obtained he had not succeeded in finding a slide showing a glandular lining of endometrial type. Pathological support was now coming quickly. He quoted cases mentioned by Lockyer and Cullen of ovaries which contained islands of uterine tissue, six in all, and finally referred to an abstract published in the *BRITISH MEDICAL JOURNAL* of February 4th, 1922 (Epitome, No. 117), of a paper contributed by Sampson to the *American Journal of Obstetrics* on "Perforating haemorrhagic cysts of the ovary." Sampson believed that these cysts were haematomata of endometrial type and gave reasons for this opinion; he believed also that the material escaping from the cysts might give rise to widespread adenomyomata. Dr. Donald thought it was interesting that on purely clinical grounds he should have formed an hypothesis similar to that reached by pathological research.

Chronic Endocervicitis.

Dr. J. W. BURNS (Liverpool) read a paper on chronic endocervicitis and its treatment. He had made a close study of the bacteriology, pathology, and treatment of this condition in eighty-four cases, and had reached the following conclusions: (1) Chronic endocervicitis should be recognized as a distinct pathological entity apart from endometritis. (2) Any discharge from the vagina which induced discomfort in the patient was pathological and usually due to chronic infection of the cervical canal. (3) That the condition was an infective one was proved by the fact that a positive culture could be obtained in 92 per cent. of cases. In 50 per cent. the staphylococcus, either alone or in association with some other organism, was present. (4) Applications of various drugs, douching, tamponnage, etc., only gave temporary relief because the antiseptics did not reach the infecting agent in the lumen of the glands. (5) Ionization brought about a marked improvement in those cases where no erosion was present. (6) For those cases associated with erosion the only successful method of treatment was the removal of the lower two-thirds of the cervical canal including the erosion.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of the West London Medico-Chirurgical Society was held at the West London Hospital on May 5th, with Sir G. LENTHAL CHEATLE, the President, in the chair.

Mr. O. L. ADDISON showed a case of chronic empyema in a young girl. Repeated operations had been performed with a view to closing the sinus, including the removal of the ribs overlying the cavity drained by the sinuses. These had all proved useless. He had therefore freely opened the chest

and deoorticated the lung over an extensive area. The result had been a complete success.

Mr. D. DENHAM PINNOCK showed a well-marked case of osteochondritis coxae in a boy. He thought that trauma was probably responsible for the condition. In a discussion on the case, Mr. O. L. ADDISON said that in his experience the treatment of the condition did not cause any anxiety, as he had seen cases in which radiography had shown marked changes in the head of the femur recover completely by simple splinting of the hip-joint. Mr. PINNOCK also showed a boy with pronounced coxa vara on both sides, probably due to late rickets. Walking had been difficult owing to "scissor leg" deformity. He had performed subtrochanteric osteotomy on one side, and the child now walked well with only a slight limp. Skiagrams were shown illustrating the condition both before and after operation.

Mr. NEIL SINCLAIR showed a case of actinomycosis of the mandible and cheek in a woman; the condition was responding well to large doses of potassium iodide after removal of several carious teeth.

Mr. RODNEY MAINGOT showed a case in which diaphysectomy of the lower third of the femur had been performed for acute osteomyelitis. Complete regeneration of the bone had taken place, and no shortening of the limb had resulted.

Other cases of interest were shown by Dr. L. C. BURRELL, Dr. J. BURNFORD, and Mr. B. SANGSTER SIMMONDS.

MEDICAL ASPECTS OF PENOLOGY.

AT a meeting of the London Association of the Medical Women's Federation held on May 16th at the Elizabeth Garrett Anderson Hospital, London, when the President, Dr. L. M. MARTINDALE, was in the chair, Miss MARGERY FRY, J.P., honorary secretary of the Penal Reform League, spoke on the medical aspects of penology. There was, she said, a need for women with special training in psychology to act as prison medical officers, and also for more skilled nursing in many prison hospitals. She emphasized, however, that there was a much wider field for trained medical minds in the whole treatment of criminals than that afforded by the old conception of the prison medical officer as the man or woman who looked after the physical health of prisoners undergoing punishment. Whilst the lawyer was called upon to say, "What has this man done?" the doctor ought to be called upon to say, "What is to be done with this man?" Only when the causes of crime were studied in a really scientific spirit was there any hope that true remedies for crime would be discovered and applied. Already under the Birmingham scheme certain classes of criminals—for example, those repeating the same offence again and again without apparent motive—were being individually examined with a view to appropriate treatment. Miss Fry pleaded for a wider study from the medical point of view of the problems of criminology, urging that the present treatment in prisons was unscientific and therefore wasteful. A short paper by Dr. MARY GORDON on the same subject was read in her absence by Dr. CONSTANCE LONG, and a discussion followed in which Mrs. SCHARLIEB, Dr. MARY BELL, Dr. MINA DOBBIE, Dr. CHRISTINE MURRELL, and others took part.

LIFE TABLES.

AT a meeting of the Royal Statistical Society in the hall of the Royal Society of Arts, on May 16th, with the President, Sir R. HENRY REW, in the chair, Dr. MAJOR GREENWOOD opened a discussion on the scientific value of life tables. Dr. Greenwood submitted that the value of a life table as an instrument of research had been somewhat overestimated, and that the opinion that important deductions could be drawn from local life tables which were not deducible from the death rates at ages was mistaken. A life table was an artificial product; its population was a fiction. It was not correct, for instance, to say that the average length of life of an English male was given by the "expectation of life" of any national table. An "expectation of life" was deduced from the rates of mortality of contemporaneously observed lives and the comparison of such constants for different life tables was open to numerous criticisms. In Dr. Greenwood's opinion, a medical officer of health would learn little more from a life table than from death rates at ages.

DR. CARTEADO MENA has been elected president of the Portuguese Medical Association.

THE annual meeting of the German Ophthalmological Society will be held at Jena from June 8th to 10th. Further information can be obtained from the secretary, Professor Henker, Bismarckstrasse 17, Jena.

Reviews.

VITAMINS.

The Vitamins,¹ by Professor H. C. SHERMAN and Dr. S. L. SMITH, is one of an "excellent series" of monographs on scientific and technological subjects published by the American Chemical Society. They have two purposes: first, to present the knowledge available upon a chosen topic in a readable form intelligible to those whose activities may be along a wholly different line; and secondly, to furnish a well-digested survey of the progress already made in a particular field, and to indicate directions in which investigation needs to be extended.

The volume under review fulfils both of these purposes. It is divided into five chapters—namely, an historical introduction; three chapters devoted to the three different vitamins, and a final chapter dealing with the vitamin supply in normal diets; there is also a bibliography containing about a thousand carefully-selected references.

The general reader will probably be most interested in the final chapter, for in this the authors discuss the question how an adequate supply of vitamins in the human diet can be ensured. The discussion is of necessity rather vague, for we have very little information as to the quantities of the various vitamins which are necessary to maintain health in man, and we have no accurate quantitative knowledge of the vitamin content of foods. Many interesting observations are made, however, as to the relative value of foods as sources of vitamins. The superiority of milk over meat in this respect is emphasized and the importance of vegetables and fruits is also very clearly shown. The practical suggestion is hazarded that in a normal family in order to ensure a dietary fairly balanced as regards mineral elements and vitamins at least as much should be spent on vegetables and fruit as upon meat and fish, and at least as much upon milk in its various forms as on all forms of flesh food. Calculations of this nature must of necessity be very vague, but these provisional attempts to estimate what diets are likely to provide an adequate vitamin supply are of very great general interest.

Those who are engaged upon research work on vitamins will find that the three chapters devoted to the three vitamins contain a clear and concise account of all the more important work which has been done, and that a particularly full account is given of the knowledge available concerning the chemical and physical properties of vitamins. Such workers will perhaps welcome most of all the excellent bibliography provided: more than one-half of the thousand references refer to work published in the last four years, and 190 to work which appeared in 1921. This means that the present output in vitamin literature is a paper every other day. These figures indicate better than anything else the great value of monographs such as that before us. It is impossible for anyone to keep in touch with modern scientific literature except along one particular line. Hence the only way in which the evils of narrow specialization can be avoided is by the study of monographs of the type of this.

FUNCTIONAL NERVOUS DISORDERS.

OF books dealing with the various different aspects of functional nervous disease the number is legion, and it is not easy either to express any original opinions or to compress the current views of theory and practice into a concise form. Dr. CORE² may, at any rate, be congratulated on the production of a volume much of which is original, though we fear that its size and the somewhat verbose nature of its method may militate considerably against any wide diffusion of his opinions. Much of his nomenclature, again, is unfamiliar, and his classification also. Hence the reader who desires really to profit by this book would do well to study the preface carefully.

In a short review it is impossible to enter fully into all the opinions expressed in the book. The functional nervous disorders are classified broadly into two main groups: (1) Regressive—that is, hysteria, which is again subdivided into

¹*The Vitamins*. By H. C. Sherman, Professor of Food Chemistry, Columbia University, and S. L. Smith, Specialist in Biological and Food Chemistry, U.S. Department of Agriculture. The American Chemical Society Monograph Series. New York: The Chemical Catalog Company, Inc. 1922. (Med. 8vo, pp. 255; 20 figures. 4 dollars net.)

²*Functional Nervous Disorders: Their Classification and Treatment*. By Donald E. Core, M.D., M.R.C.P. Bristol: John Wright and Sons, Ltd. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1922. (Med. 8vo, pp. xii+371; 21 figures. 25s. net.)

primary, secondary, and tertiary; and (2) progressive or sympathetic functional nervous disorders; these are subdivided into two groups, the instinct distortions and the memory or mnemonic disorders. Those who follow the author carefully in his reasoning will find much that is valuable and attractive in this classification.

The first three chapters are devoted to some general considerations, where the psychology of animals and that of man is compared in their evolutionary and environmental aspects. The regressive group of disorders, hysteria in its different clinical forms, are considered in detail in the second part of the book. The second great group, the progressive or sympathetic nervous disorders, are then fully described. The reader will perhaps be surprised to learn of the characteristic association of a mnemonic disorder with a raised blood pressure and to find the view expressed that a mnemonic disorder is a prodromal phase of arterial degeneration. The subject of dreams and the much-vexed question of the sex instinct as an etiological factor are discussed in a separate chapter. Chapters on diagnosis, prognosis, and treatment complete the book.

The author has wisely included a summary of contents at the end of each chapter, for his style is not easy and his nomenclature will add to the difficulties of any reader not familiar with psychological literature. As a whole the book is altogether too polix, while the form of its expression is unnecessarily verbose. These are unfortunate faults, for there is much that is very valuable in the author's conclusions, which have obviously been reached as the results of careful and painstaking study.

GLAUCOMA.

THE fact that a second edition of ELLIOT's *Treatise on Glaucoma*¹ has been called for within four years of the publication of the first proves that the book has been appreciated. Its general characters are well known to all who have perused the earlier edition; the author adopts the attitude of a student who seeks by a survey of the literature, and from his clinical and pathological knowledge of the disease, to bring some sort of order out of the chaos which even now surrounds his subject.

We think Colonel Elliot is right in regarding his book not quite as a textbook, in which, more often than not, a dogmatic attitude is adopted intentionally by the author, but rather as a treatise in which everyone is given a fair hearing, and the reader is left to draw his own conclusions.

The new edition has been brought up to date; some parts of it have been rewritten and additions have been made, fresh papers on the subject up to January, 1922, having been laid under contribution. The result is a bulky volume which will be of great value to ophthalmic surgeons throughout the English-speaking world, and also to those students who are studying for the higher degrees and diplomas in ophthalmology.

A feature of the book is the valuable bibliography provided at the end of each section or chapter; the full index of authors and subjects completes a work which is a noteworthy contribution to the literature of its subject. The publishers have done their share in its production excellently.

RADIOGRAPHY.

IN *The Principles of Radiography*,² Dr. J. A. CROWTHER, the lecturer in physics applied to medical radiology in the University of Cambridge, has endeavoured to give an intelligible but non-mathematical account of the physical principles involved in the production of a radiogram, and in the construction and use of the apparatus employed for the purpose. It is based on the lectures given to students for the D.M.R.E. Cambridge, and fills what has been a distinct want, inasmuch as the ordinary textbooks of physics are not primarily concerned with the needs of medical men who specialize in radiography. In general construction the book is divided into ten chapters, which deal successively with electrical phenomena, the electric current, the induction of currents, electricity in gases, x rays, the x-ray tube, the production of high-tension currents, the x-ray installation, the

making of a radiogram, and the localization of foreign bodies. It is all written in very simple language, and the diagrams are adequate to illustrate various points which otherwise might not be easy to understand. There are also a few radiographic reproductions, but it is unfortunate that one of these is described as showing a fracture of the humerus, whereas in reality it seems to be a fracture of the lower end of the femur. We note that in two places it is stated that the discovery of x rays was made by Röntgen in 1894, but it should be remembered that the paper announcing the discovery appeared in December, 1895. The chapter on the localization of foreign bodies is somewhat inadequate, and the simplest of all methods, by a single shift of the tube after first of all centring on the foreign body, is not explained. In any future edition this chapter should certainly be revised. As a whole the book fulfils its purpose, and should be useful to those commencing the study of radiology.

L'Emploi des Rayons X en Médecine,³ by Dr. PAUL DUHEM, is a book which in a short and concise manner covers the whole ground of x-ray work from the points of view of instrumentation, diagnosis, and treatment. In effect it is a general statement as to the position of x rays in medical work, and is obviously intended rather for the student and general practitioner than the specialist. The illustrations are almost entirely diagrammatic. It is one of a series—"Bibliothèque des Connaissances Médicales"—appearing under the editorship of Dr. Apert.

The First Aid X-ray Atlas of the Arteries,⁴ by Mr. H. C. ORRIN, consists of nine plates, reproductions of radiographs of the various arteries injected with an opaque material, and a short account of each plate. It is intended for lecturers on first aid, and will be of value to them in teaching the arterial system to their students.

THE DEVON AND EXETER HOSPITAL.

DR. HARRIS's *History of the Royal Devon and Exeter Hospital*⁵ is a valuable work. It records minutely, from year to year, the growth and development of an important medical charity in all its departments, from its foundation in 1741 to the year 1905. The book is full of interesting information on administration and finance, on the honorary staff and their work, on the paid staff, the nursing, and the story of the medical school. It is replete with biographies of benefactors, medical officers, and others, and contains many anecdotes and valuable pictures of the times.

The record presented is a notable one. The institution was the second provincial hospital established in England, owing its foundation to the same man who founded the first. Dean Clarke, when Prebendary of Winchester, had established in 1736 the present Royal Hants County Hospital, and, although he was a sick man when appointed Dean of Exeter, he lost no time in setting on foot a scheme for a large hospital there also. The present Royal Devon and Exeter Hospital was founded by him in 1741, but unhappily before its opening two years later the Dean was dead. The impetus he gave outlived him, as we see from the foundation in Exeter in 1808 of the first eye hospital in England outside London, and that only four years later than the foundation of Moorfields itself.

The Dean's generous co-founder, Mr. John Tuckfield (who by the way was twice Member of Parliament for Exeter) the donor of the land on which the hospital is built, also left an enduring example. For, as this book shows, the charity has been singularly fortunate in the loyalty and generosity of the support accorded to it both by county and city. Some years ago, when the question arose of economy by closing some wards, one of the staff was able to show that it was the most richly endowed hospital of its size and sort in England, and the wards remained open.

A benefactor of its early days, whose portrait hangs in the boardroom, near those of Dean Clarke and Mr. Tuckfield, was Mr. Ralph Allen, the friend of Fielding. Believed to be the original of Squire Allworthy in *Tom Jones*. In connexion with this may be mentioned the fact, which Dr. Harris

⁴ *First Aid X-ray Atlas of the Arteries*. By H. C. Orrin, O.B.E., F.R.C.S. Edin. London: Baillière, Tindall, and Cox. 1922. (Foil 8vo, pp. viii + 47; 9 plates, 11 figures. 2s. 6d. net.)

⁵ *The Royal Devon and Exeter Hospital*. By J. Delprat Harris, M.D. Exeter: Hland Brothers. 1922. (Demy 8vo, pp. 205; illustrated. 5s.)

relates, that one of the staff, a Dr. Rhodes, was the son of the lady supposed to have been the original of Sophia in the same famous novel. There seems no doubt that Fielding fell deeply in love with her, but the lady he ultimately married is said by some to have been the real Sophia.

Dr. Harris's interesting speculations on the origin of the great philanthropic movement of the eighteenth century in England omits one powerful factor emphasized by John Richard Green—namely, the wonderful and widely carried mission of the Oxford men who clustered round John and Charles Wesley. Dean Clarke, however, though he must have been influenced by this Oxford movement, was himself a Cambridge man, a Fellow of Corpus.

The staff of the hospital, whose careers, where possible, are carefully sketched, have been a distinguished body of men. Two have been Fellows of the Royal Society—namely, Dr. Bartholomew Parr, physician 1775 to 1809, who published a bulky *London Medical Dictionary*; and Mr. John Sheldon, surgeon 1797 to 1808, whose book on the *History of the Absorbent System* was considered an excellent piece of work. Two of the physicians also made notable original advances in medical knowledge whose value persists—namely, Dr. John Blackall, physician 1807 to 1847, the forerunner of Bright, who in his work, *Observations on the Nature and Cure of Dropsies*, pointed out the relation between albuminuria and dropsy; and Dr. Thomas Shapter, physician 1847 to 1876, whose volume on the *Climates of South Devon* was a valuable contribution to climatology. One of the surgeons, Mr. John Haddy James (1816 to 1858), was the second to tie the abdominal aorta for aneurysm. It was this surgeon who, with his colleague Mr. Samuel Barnes, established the medical school in Exeter. The staff had always had pupils, but in 1819 more systematic teaching was introduced and a "larger number" of pupils attended. This continued till about 1863, when new regulations for medical education had caused the numbers to decline.

It is interesting to notice how many of the earlier staff had studied abroad—Mr. John Patch in Paris, Dr. Dieker, Dr. Glass, and Dr. Hallett under Boerhaave at Leyden. One of the staff, Dr. Kempe, was an important benefactor of the hospital, building its chapel at his own expense. The library and museum, Dr. Harris tells us, were established in 1813, the nursing training school in 1890.

Two omissions—which, in the huge mass of detail with which he had to deal, have escaped Dr. Harris's attention—must be noted. The one is the inauguration of systematic note-taking of the cases by Mr. Russell Coombe about 1889 when he was senior house-surgeon, and the other the admission of the staff to ample official representation on the Hospital Committee about 1897—a change which has admittedly been of the greatest benefit to the institution.

Dr. Harris has naturally refrained from reference to living officials, but it would be unfair to close this brief notice of the valuable service rendered to the hospital by him as its historian, without mentioning its further debt to him in the organization of the present fine electrical department.

NOTES ON BOOKS.

UNDER the title of *Post-Graduate Lectures*⁸ ten lectures to graduates delivered before the Fellowship of Medicine at the house of the Royal Society of Medicine in 1919 and 1920 have just been published. In a preface which he has written for the volume Sir Clifford Allbutt says that the perusal of the lectures will go far to convince the most self-contained practitioner that in our time without periodical class teaching and co-operative practice he cannot efficiently equip himself, nor do full justice to his patients. The subjects of the lectures include: "Syphilis and insanity" and "Morbid mental growths," by the late Sir George Savage; "The prognosis of exophthalmic goitre," by Sir W. Hale White; "Grave familial jaundice of the newly born," by Sir Humphry Rolleston; "The value of combined treatment, with special reference to surgery, electricity, and x rays," by Dr. F. Herniman-Johnson; "On the after-effects and so-called after-effects of anaesthetics," by Mr. J. D. Mortimer; "Chronic paroxysmal trigeminal neuralgia and its treatment," by Dr. W. Harris; "Pyorrhoea alveolaris and its relationship to disease," by Dr. N. Mutch; "Disabilities of the foot due to static or mechanical causes" and "Deformities and disabilities of the foot due to paralysis," by Mr. W. H. Trethowan. The publication of these lectures is an extension of the work of

the Fellowship of Medicine upon which it is to be congratulated. The standard of the lectures is high, and all are well worthy of being given permanence in this form, so that a wider public may now appreciate them. The volume is well printed and produced.

Mr. Hugh Macnaghten, Vice-Provost of Eton College, has written a pamphlet⁹ in appreciation of M. Emile Coué and his work. In this he tells how he came to visit the auto-suggestion centre at Nancy in search of relief from insomnia, and describes in some detail the *conférences* held lately by M. Coué in this country. With regard to the formula which has become a household word in clinics; every stratum of society, the author observes: "We shall therefore, as good children, continue saying 'Every day in every respect I am getting better and better,' though we shall not fail to realize as sane men and women that it is the condition of mind and not the repetition of formulae which is responsible for the daily improvement." The sincerity and literary charm of this pamphlet will be apparent to every reader. Mr. Macnaghten writes with an obvious desire to help others, but in his closing paragraph he seems to admit that after seven weeks' discipleship he is hardly yet in a position to speak with an air of finality about any benefit he himself has received. It is, however, common knowledge that self-confidence is half the battle in overcoming sleeplessness.

MEDICAL AND SURGICAL APPLIANCES.

Radium Applicator Forceps.

MR. C. P. G. WAKELEY, F.R.C.S. Eng. (Assistant Surgeon, King's College Hospital), writes: The insertion of tubes containing radium is not always quite so simple a matter as may appear at first sight, especially when there is any resistance to be overcome as in the case of fibroid tumours or other firm growths. In such cases it only too frequently happens that the radium applicator is seized with a pair of Spencer Wells forceps or any other tightly gripping instrument that happens to be available, with the inevitable result of damaging the tube. The applicator forceps indicated in the accompanying sketch has been made to my design by Mr. J. H. Montague of 69, New Bond Street, W.1. It holds the radium tube firmly, and, not allowing of lateral movement, does not scratch or otherwise damage the tube.

VENEREAL DISEASE AND SEX EDUCATION.

REPORT BY A SWEDISH GOVERNMENT COMMITTEE.

According to the temperament and education of the individual, venereal disease is regarded in widely different lights. It may seem an isolated phenomenon to be prevented by mechanical and chemical means and to be treated by chemical means alone. Or it may be regarded as the culmination of a long series of events to which an almost infinite variety of forces have contributed. Of both views there are eloquent exponents in this country. It is, however, conceivable that more knowledge may be gained by observing how the problem is dealt with abroad than by concentrating attention on its controversial discussion at home. The problem is, indeed, the same at home and abroad, but the solutions proposed are not always identical. The framers of the Swedish venereal disease law of 1918 had a lively sense of the importance of general enlightenment with regard to venereal disease and germane subjects, such as sex hygiene, and they explicitly stated that provision must be made for such enlightenment. In accordance with this injunction a Committee was appointed, in October, 1918, consisting of experts in medicine and pedagogy, to investigate the ways and means by which popular enlightenment might best be provided. Their Report,¹ recently issued, is a document of considerable value, promising to become the charter of a new and complete system of sex education and hygiene in schools throughout Sweden.

The Education of the Child.

In their introductory remarks the signatories point out that the recent venereal disease law recognized and specifically referred to the need for education of the public with regard to venereal disease and its consequences, but no definite lines

¹ *Rehäskande Angående Åtgärder för Spridande av Kunskap om Könssjukdomarnas Natur och Smittfärlighet* M. M. Stockholm. 1921; pp. 232.

⁸ *Post-Graduate Lectures*. With a preface by Sir Clifford Allbutt, P.C., K.C.B., M.D., F.R.S. London: J. Bale, Sons, and Danielsson, Ltd. 1922. (Demy 8vo, pp. xiv + 216. 10s. 6d. net.)

were laid down as to the detailed course to be pursued. To sound school teachers on this point the Committee addressed a set of questions to various teaching institutions throughout Sweden, and the answers they obtained are analysed in a supplement of the Report. Much of the Report is concerned with a detailed and comprehensive scheme of sex education, extending from the pre-school age to adult life. It is illustrative of the broad view taken by the Committee of their task that they deal with the education of the child from the time it learns to speak and address inquiries as to how it came into the world. The Committee look forward to the time when parents will be so enlightened that they will not tell their children silly stories about babies being brought into the home by storks, but will give a simple account which the child in later years will not discover to be mendacious. The Committee hope that the child, who is gradually taught more and more about sex hygiene as it passes from one school grade to another, will eventually become a parent wise enough to instil in the next generation a frank and healthy attitude towards sex problems. Parents, it is hoped, will learn to protect their infants from the undesirable caresses and kisses of strangers, and to discourage a child from sharing a bed with other children or adults. As for sex teaching in school, this should be associated with the teaching of biology, Christianity, sociology, and psychology. The question of venereal disease should not come into the curriculum until comparatively late, and until the physiology of fertilization and reproduction has been fully taught. Advanced sex teaching should preferably be in the hands of doctors, but they are not always available, in which case other teachers should give instruction on this subject, male teachers dealing with boys and female teachers with girls. Teaching of sex hygiene in high schools for girls should include the subject of venereal disease, and special emphasis should be laid on the protection of infants from infection. A further recommendation is that a carefully supervised library of works on sex hygiene and venereal disease should be compiled at the cost of the State for the use of teachers and classes.

Personal Prophylaxis: Minority Report.

The law of 1918 indicated the need for teaching the public how to prevent spread of infection, and in attempting to follow this injunction the Committee have encountered the same difficulties experienced in every other country in which personal prophylaxis has been discussed. One of the members of the Committee, C. K. S. Sprinchorn, Rector and Doctor of Philosophy, who has contributed a comprehensive survey of the campaign against venereal disease in many different countries, and has published this survey in the form of a supplement to the Report, has not been able to agree with his colleagues over the matter of personal prophylaxis, and he has accordingly published a short Minority Report on this point. In this he argues that at one and the same time to teach the rising generation a high standard of ethical and moral responsibility and to give instruction how to evade the consequences of immorality is to land the teacher on the horns of a dilemma. He notes that recruits in the Swedish army are given compulsory training in prophylaxis, and that by this means knowledge of such prophylaxis will gradually be acquired by the whole male population. There are also several other means already available by which such knowledge can be gained, and he is disinclined to push the teaching of prophylaxis in further detail till the effects of measures already in force can be gauged.

Personal Prophylaxis: Majority Report.

Like Dr. Sprinchorn, the other members of the Committee regard the question of personal prophylaxis as a most delicate subject, concerning which it is not possible to walk too warily. They deputed one of their members, Dr. Karl Marcus, medical superintendent of St. Göran's Hospital, and lecturer on venereal disease, to prepare a separate report dealing with the purely medical aspect. Commenting on this supplement to the sponsors of the Majority Report seem to agree as to the desirability of issuing pamphlets and other publications, detailing the merits and technique of personal prophylaxis, but they insist that in their scheme of sex education the teaching of personal prophylaxis should not be compulsory, the matter being left to the discretion of the teacher. They also recommend that doctors alone should venture on this subject, and they suggest other restrictions which reflect the hesitation in the minds of the Committee on this point.

The Value of Personal Prophylaxis.

The review by Dr. Marcus of this subject consists largely of abstracts from Neisser's work *Die Geschlechtskrankheiten und ihre Bekämpfung* (Berlin, 1916). He adds some observations recently made in Sweden which, in his opinion, afford further proof of the efficacy of personal prophylaxis. For some years this has been obligatory in the Swedish navy, and it has been most strictly enforced when foreign ports have been visited. During the overseas expedition of the *Fylgia* in 1913-14 only two men became infected, and one of them was found not to have carried out prophylactic treatment. In the period 1919-20, of 557 men given prophylactic treatment only 13 developed venereal disease, and in no case was syphilis contracted. Reporting on this matter the chief medical officer of the Swedish navy has declared this result to be excellent, considering that the incidence of venereal disease among prostitutes in the West Indies is said to be about 95 per cent. In 1912 Dr. Möllern-Aspegren calculated that in men the primary syphilitic lesion was situated in strictures unprotected by the condom only in 2.4 per cent. of all cases. In the case of gonorrhoea it is, according to Dr. Marcus, still more effective than in syphilis.

Mechanical or Chemical Prophylaxis?

Dr. Marcus notes that most of the statistics hitherto published refer to chemical prophylaxis, but he appears to agree with Professor Blaschko in regarding the condom as the device which confers most complete protection against venereal disease. The contraceptive properties of the condom have biased the opinions of certain authorities in its disfavour, but Dr. Marcus remarks that where prostitution is concerned these properties can hardly be regarded as a disqualification. As for the part played by the condom in wedlock, he considers it secondary to other contraceptive practices. In favour of this appliance it has been argued that sterility induced by gonorrhoea robs Germany alone of 200,000 new citizens every year, and that the annual cost to Prussia alone of venereal disease is 92 million marks. The use of the condom is urged as being justified if it reduces, as Dr. Marcus clearly thinks it does, the number of infections in wedlock, of criminal abortions, of illegitimate children, of women who take to prostitution on account of pregnancy or venereal disease, and of men who remain unmarried because they have contracted venereal disease.

Contraceptives and the Birth Rate.

Dr. Marcus is profoundly sceptical as to the wisdom and effectiveness of legislative measures penalizing contraceptives. He asks, and answers in the negative, the question—Have ten years of anticontraceptive legislation checked the decline in the birth rate? Between 1911 and 1919 there has been a uniform decline in the birth rate in Sweden, the figures for 1911 being 23.99 per 1,000, while for 1919 they were 19.64. On the other hand, the incidence of venereal disease has increased greatly in this period; in 1913 there were 14,035 new cases of venereal disease, in 1918 this number had risen to 24,088, and in 1919 to 30,429. In these last two years the importation of contraceptives was greatly restricted by the commercial blockade. Dr. Marcus concludes from these figures that the condom plays a part of secondary importance as a contraceptive in wedlock, other measures such as coitus interruptus and criminal abortions playing a far more important part. He quotes Professor Forssner as stating in 1920 that in Stockholm the birth rate had fallen between 1900 and 1919 from 26 to 13 per 1,000. Within the same period the number of abortions has increased enormously, 21 per cent. of all pregnancies being now terminated by abortion, the criminal induction of which has become a most serious factor in the birth rate.

Dr. Marcus traces the evolution of the education and opinions of the medical profession in Sweden on this point. He shows that as recently as ten years ago there were practically no statistics illustrating the value of personal prophylaxis, and declares that the attitude of the doctors in Stockholm towards this matter was nebulous and prejudiced. In 1911 and 1912 a series of hot debates were held in the Swedish Medical Society, and Dr. Möllern-Aspegren's advocacy of personal prophylaxis was supported only by 12 out of 64 votes. When, in 1916, Strandberg addressed the same Medical Society on the value of personal prophylaxis as demonstrated by the war, no opposition was raised.

The Committee calculate that their scheme of popular education will involve an annual expenditure of kr. 31,200.

in addition to an initial outlay of kr. 2,000 on drafting standard pamphlets and other literature. The chief item in this budget is the sum of kr. 14,500 for lectures. Other items are: kr. 5,000 for lecturers' travelling and kr. 5,000 for printing and other expenses.

The Future.

There are indications in this Report that ultimately the present difficulties with regard to personal prophylaxis may be more or less automatically solved in Sweden. For there is every prospect of coming generations acquiring knowledge as they grow up, which will shift the responsibility for contracting venereal disease directly on to the persons most concerned. Practically every adolescent will know the rudiments of venereal disease, the means whereby the risk of infection can be somewhat reduced, and how to obtain and use such means. This knowledge will have been gained gradually, systematically, and under the supervision of responsible teachers, who will have taught physiology and pathology with a goodly leaven of ethics. Thus a state of affairs will, it is hoped, exist quite unlike that now obtaining.

THE TEACHING OF MEDICINE AND SURGERY.

NEW PLANS OF THE LEEDS MEDICAL SCHOOL.

(From Our Correspondent.)

It will be remembered that some weeks ago—on January 7th of this year—an account was given at page 21 of certain arrangements which were being put in operation to improve the teaching of medicine and surgery at Leeds. It was pointed out that the "unit" system was not deemed suitable for Leeds, but that it had been decided to appoint three whole-time men, one on the medical and two on the surgical side, to take a very active part in the teaching of the students, not only of course by didactic instruction, but by assisting them in investigating the cases entrusted to them and by the conducting of tutorial classes and in other ways.

In our previous article an account was given of the plans which had been outlined for the teaching on the medical side of the house, and it is proposed now to give in outline some indication of the arrangements for the teaching of surgery.

The teaching of surgery at the university and at the infirmary has up till now consisted of—

1. Lectures in systematic surgery by the professor of surgery on Tuesdays and Saturdays from 9 to 10 a.m. during the second and third terms. The number of lectures has been approximately fifty.
2. Lectures on practical surgery on Mondays and Thursdays at 12 noon to 1 p.m. during the second and third terms. Approximate number, forty.
3. Classes on operative surgery. No fixed number of lectures was given. Special arrangements were made for each course.
4. Ten lectures by the professor of clinical surgery during the first term.
5. Clinical lectures every fortnight during all the three terms by the full staff and the assistant staff.
6. Ward teaching from 10 a.m. to 12 noon during all terms.
7. Teaching in the out-patient rooms four afternoons a week.
8. Preliminary instruction by the surgical registrar (a) to students just entering on hospital practice; (b) to in-patient dressers.

The most radical change is the abolition of the course of systematic surgery, and the reduction of the course of lectures on practical surgery to five or ten demonstrations of operations upon the cadaver.

The instruction in future will therefore consist of the following:

1. An inaugural lecture to all students by the professor of surgery.
2. Preliminary instruction and recapitulation classes by the new officers, who will be termed surgical clinical assistants.
3. Instruction by the assistant staff—namely, (a) practical demonstrations in conjunction with the staff of the medical department of the university and the radiographer, and (b) clinical demonstrations on Saturday mornings on cases in the casualty and isolation departments.
4. Instruction by the full staff surgeons—namely, (a) ward teaching, (b) clinical lectures, single or in series, and (c) lecture demonstrations as detailed later on.

As regards the second of these methods of instruction it is intended that all students who, having passed the second M.B. or corresponding examination, enter upon their period of clinical work shall receive instruction from the clinical assistants.

The syllabus will be on the following lines:

- A. *Sepsis, Asepsis, Antisepsis.*
 1. General principles.
 2. Bacteriology of wound infections (by the professor of pathology or his representative).
 3. Technique of aseptic and antiseptic methods: (a) Results of good technique; mode of healing; mortality and morbidity of operations. (b) Results of bad technique; suppuration, etc., secondary haemorrhage, phlebitis, etc.
 4. The general conduct of operations: (a) Preparation of patient, preliminary and immediate; narcosis. (b) Details of operation, "team" principles, haemostasis, drainage, etc. (c) Post operation treatment.
 5. The technique of dressings, catheterization, hypodermic injection, etc.
- B. *Surgical Anatomy* (in conjunction with the professor of anatomy), including surface markings, landmarks, etc.
- C. *Examination of Patient:*
 1. Recording clinical history.
 2. Method of examination—physical signs, condition of chest, urine, etc., from standpoint of surgeon.
 3. Method of diagnosis—general, special, rectal, catheters, specula, etc.
- D. *Method of Treatment:*
 1. General principles—temperature charts, splints.
 2. Special appliances (with representatives of other departments if necessary), instruments, infusion and transfusion, vaccine therapy.

All this teaching will be, as far as possible, practical, and carried out in conjunction with the departments of anatomy, physiology, and pathology. The out-patient and in-patient material of the hospital should be at the disposal of the teacher, not for discussing the details of individual cases, but for a general comparison of the physical signs in a series of similar cases—for example, tumours of the breast, thyroid, abdomen, and so forth.

The instruction by the assistant staff will take the place of that formerly covered by the course of lectures in systematic surgery. It should be mentioned that that part of the old syllabus which concerns bacteriology, inflammation, gangrene, parasitic and infectious diseases, including syphilis and gonorrhoea, growths, the constitutional effect of injuries and other matters, have been cut out on the ground that they are dealt with by others. Thus the constitutional effects of injuries will be dealt with by the full staff; gangrenes, etc., by the assistant surgeon in charge of the isolation department.

A detailed and comprehensive syllabus is framed for four assistant surgeons over a period of two years—ten lectures in each of the two terms (January to March and April to June). All lectures and demonstrations in the syllabus will be illustrated by cases, specimens, diagrams, radiograms, etc., whenever possible. The co-operation of the scientific departments of the university will be requested as often as is needed for the full and adequate teaching of the several subjects. The following note appended to the syllabus indicates the spirit in which the courses have been designed:

"At these demonstrations the general method of teaching shall be as follows: General introduction of the subject; demonstrations in the anatomy or pathology, or physiology, of the part, with exhibition of specimens or dissections (in conjunction with the staff of the departments concerned); demonstrations of cases with such clinical discussion as may be necessary, methods of examination, diagnosis and treatment, with demonstrations of any special appliances, trusses, splints, etc. When necessary a series of cases of the condition under consideration shall be collected, and a day arranged for operation upon them, before the class. All material of the hospital shall, as far as practicable, and by arrangement with other members of the staff, be at the disposal of the assistant surgeon for teaching purposes. The assistant surgeon will probably arrange to give special attention to the subject on which he is demonstrating when he is seeing his out-patients in the ordinary way at the infirmary. The out-patient teaching shall be continued on the same general conditions as at present. It is hoped that arrangements can be made by the infirmary authorities for each assistant surgeon to see out-patients. It was decided that the fourth assistant surgeon should supervise the theatre technique, sterilizing, etc., and furnish a report to the committee from time to time. On Saturday mornings clinical demonstrations on cases in the casualty and isolation departments shall be given by the assistant surgeons. The detailed arrangements for this course will be published from time to time."

In regard to instruction by the full staff, it is proposed that the in-patient teaching shall be arranged as follows: (a) Mondays, Tuesdays, Wednesdays, and Thursdays, 1 to 12, to be allotted, one day each, to the four surgeons

ward teaching; (b) Fridays, 10 to 12, to be allotted in October, January, and May (the first months of each term) to the professor of surgery; and (c) that the remaining two months in each term should be given to the three other surgeons in rotation (for example, November and December to Surgeon A, February and March to Surgeon B, June and July to Surgeon C). On Fridays it is suggested that the teaching should be decided by the surgeon himself; ward teaching, lectures, or clinical lectures, singly or in series, or lecture demonstrations, being given as the surgeon wishes to arrange. To these proposals the following note is added:

"Lecture demonstrations shall be given in conjunction with the professors of anatomy, physiology, and pathology, one of the physicians or assistant physicians, and the radiographer, upon a subject selected beforehand and arranged in consultation with the other surgeons, which shall be fully described and discussed and demonstrated upon patients collected from in-patient and out-patient departments as may be necessary. Material for the creasion shall be offered to the surgeon by all his surgical colleagues as generously as possible. The selection of members of the university or infirmary staff invited by the surgeon to take part in the lecture demonstrations will depend upon the subject chosen. On these occasions cases should be collected for a few weeks beforehand by clinical assistants, etc., and shown at the lecture demonstrations in various stages before and after operation; and a day in the following week could be set aside for operating before the class upon any of the cases examined at the demonstration. The preparation of material for these lectures will require special assistance. It will be impracticable for the Surgeon himself to collect clinical records, specimens, drawings, etc., for the lecture. He will need a clinical assistant."

In order that these alterations and improvements may be carried out under conditions conducive to their full success it must again be mentioned how very desirable is the provision of an instructional block. Accommodation can happily be secured at the infirmary which would fulfil the purpose admirably, but a considerable outlay will be necessary for structural alterations and for equipment. It is earnestly hoped that this may come to fruition in the near future, and if so some account may be given here of what will constitute a great improvement to the infirmary and to the school.

A HALF-CENTURY OF PUBLIC HEALTH IN NORTH AMERICA.

BY

JOHN C. McVAIL, M.D., LL.D.

(Continued from page 806.)

II.

STATE AND MUNICIPAL CONTROL OF DISEASE.

THE Jubilee volume of the American Public Health Association contains a number of articles dealing with the control of disease by States and municipalities. The article by Dr. Charles V. Chapin, lecturer in the School of Public Health, Harvard, to which reference has already been made, serves as a sort of general introduction to the subject. We gather that in the majority of small towns and rural districts there is no board of health, nor any health officer, or that if a board exists it is very inefficient. In a few instances the State has taken over local health work, but the practice of the States varies very much and probably also their legal powers.

Against small-pox, notification, isolation, disinfection, and immunization were employed from early times; so long ago as 1701 Massachusetts required places for the isolation of the disease to be provided. Little importance, it is stated, is now attached in America to terminal disinfection in the management of infectious diseases, continuous disinfection throughout sickness being deemed of more value.

Notification of venereal disease has been, in theory, compulsory in California since the beginning of 1911, and by 1915 a dozen States had followed its example. Little, however, seems to have been done to enforce the law. The chief additional features of the campaign against venereal disease are "the establishment of clinics, the education of the public, and the enforcement of all police regulations which tend to make prostitution less easy." Nothing is said on the questions so much agitated in this country as to "packets" and the rival policies of preventive and curative treatment.

The antituberculosis movement is on the same lines as in this country. The first State sanatorium was built by Massachusetts in 1898, and ten years later there were 250 sanatoriums and special hospitals throughout the United States. The tuberculosis dispensary is, however, looked on

as the most important feature of the campaign; prevention of human infection and the raising of bodily resistance are always kept in mind. Much work is done as to preventorium, open-air schools, better housing, milk and food control, and the like.

Dr. Chapin thinks rather exaggerated importance has been attached to milk for reduction of infant mortality; he says milk stations are still chiefly maintained by private effort, though the municipalities are doing more and more. A change of system, however, is, he says, taking place; the consultation for well babies, at which milk is not sold, has largely taken the place of the milk station as first established. In 1916 there were in 142 cities 95 organizations maintaining such consultations, as compared with 110 maintaining milk stations. Mention is not made here of free supply of milk. In New York City infant mortality fell from 273 per 1,000 births in 1885 to 94 in 1915. Medical inspection of schools began in 1894, and nurses were first employed in 1902.

Serum distribution seems to have been begun by newspaper enterprise in New York, but was taken over by the Health Department in 1894. State health departments are now engaged in the work. It is held that "the experience of some cities has shown that it is not enough to distribute these serums freely, but that many more lives can be saved if the Health Department stands ready to administer them."

On the relation of curative to preventive medicine Dr. Chapin says:

"For a long time it was believed by everybody that preventive medicine should keep its hands off curative medicine, and many health officers, most of the general public, and nearly every practising physician, still think so. On the other hand, there are many experienced and sagacious health officials and publicists who believe cure and prevention ought to be combined to a considerable extent in the same administrative unit."

It appears that many clinics have in fact been established by health officers.

Investigation and advice were the first conception of the health work States could do, and the valuable inquiries by Massachusetts into purification of water and sewage are specially mentioned. Health education of the public has been developed by means of lectures, automobile clinics, health trains, and other such means, but Dr. Chapin remarks that health propaganda too easily falls from the ways of the scientific teacher into those of the commercial advertiser. In the Southern States the safe disposal of human excretion has been the subject of a revolutionary campaign, especially as regards hookworm disease, and splendid aid has been given by the Rockefeller Sanitary Commission. Dr. Chapin expresses the opinion that every city of 50,000 inhabitants should have its own diagnostic laboratory, and that smaller places should be provided for by the State. Vital statistics are still defective, though now death registration exists for more than three-quarters of the population of the United States, and the area for birth registration is rapidly increasing. The New York death rate has fallen from 28 in 1869 to 12.93 in 1910. Within twenty-three years there has been a fall in the death rate of the rapidly expanding registration area equivalent to a saving of 400,000 lives yearly.

It would have been interesting had the article set forth in some detail the organization of a health department, and stated whether there is for properly qualified officers reasonable security of tenure in State appointments, or whether the spoils still go to the victors. But the article otherwise is a mine of condensed information for all interested in the subject, and the above brief notes are only samples of its contents.

A CENTURY'S MORTALITY.

Complete vital statistics for the United States as a whole do not exist, but Dr. Frederick L. Hoffman, LL.D., of the American Prudential Insurance Company, has written an article founded on material which he has collected relative to certain populations, especially New York, Philadelphia, Boston, and New Orleans, for which there exist data concerning the century 1815-1914. Taking the figures for the four cities jointly, it is shown that the death rate, which was 23.1 in the first twenty-five years and 30.2 in the second, fell to 25.7 in the third and to 18.9 in the fourth. In the five years 1916-20 the rates were 15.4, 15.6, 19.8, 14.0, and 13.7. Dr. Hoffman gives an interesting sketch of the history of mortality table construction, and submits observations on the value of such tables. On that point he writes:

"It must be readily granted that all life tables for the general population suffer from the inherent uncertainty as regards the exposed to risk. It is of necessity assumed that the age, sex, and

race distribution of the population remains the same, or is modified according to known principles during the period intervening between two census enumerations. It is further assumed that the enumeration as to age, race, and sex composition of the population has the same intrinsic accuracy as the mortality records derived from registration sources. But both of these assumptions may lead seriously astray. There is the further inherent uncertainty due to a mathematical compromise to give to life-table calculations an appearance of smoothness which may not represent the true facts in the case."

Dr. Hoffman also refers to the question of the real mortality rate in late adolescence, which, he says, is possibly lower than in early adolescence, the mortality between 18 and 21 being perhaps higher than, say, between 21 and 25. He urges that for public health purposes precise death rates by single years of life are absolutely essential, and that the application of mathematical graduation processes may give wrong impressions. In a brief history of the subject he refers to Price's Northampton life tables of 1771 and 1783, to the Carlisle table of 1815, and to the first American life table, by Edward Wigglesworth, D.D., in 1789, which he deals with in some detail, because the original is practically inaccessible. Even where the population is unknown Dr. Hoffman holds that mortality records, "when utilized with extreme care," are "of the greatest value in arriving at definite conclusions regarding the effect of the environment on the death rate." In support of this view he submits for the island of Nantucket a table and chart which indicate a material increase in the average age at death, as an approximately trustworthy indication of sanitary progress.

CHILD WELFARE.

The article on child welfare by Professor Van Ingen, of Columbia University, New York, affords evidence that a great deal is being done, but, as elsewhere in the volume, the value of the conclusions to be drawn is diminished by the fact that the vital statistics available are both recent and incomplete. Statistics for the quinquennium 1900-1904 revealed an appalling loss of life during infancy and childhood and led to the establishment in 1915 of a birth registration area and the issue of birth statistics which then for the first time, it is rather surprising to learn, "were made available for a considerable area and were compiled in a uniform manner." After dealing with such matters as child labour, the medical inspection of school children, and the efforts to secure infant and child welfare made by the Federal (National) Government, States and municipalities, and by private enterprise, Professor Van Ingen specifies four principles which he considers to be of primary importance: (1) Personal—that is, individual—contact; (2) education in simple and attractive form; (3) concentration on the mother and future mother; and (4) the availability and success of non-medical persons in carrying out plans founded on a sound medical basis.

The Child Health Organization, begun in 1918, plays a great part in America. It has interested the children themselves in many ingenious ways and has instituted Health Crusaders, Camp Fire girls, and Little Mothers' Leagues. Infant welfare work has greatly developed in respect of medical attendance for the poor, but as regards the provision of pasteurized milk and other such measures it was found that artificial feeding was thereby stimulated, and "with experience the tendency increases everywhere to place more emphasis on trained supervision and educational work."

Pre-natal work is receiving attention, but is somewhat limited "owing to an effort to make the work as nearly self-supporting as possible." The first school in America for the training of midwives was established at Bellevue Hospital at the face of considerable opposition, the nature of which is not explained. Many States now require registration of midwives, but few supervise them, and until recently hardly any provided for their education. Yet it is said that comparison of results as between midwives and doctors has not always been to the advantage of the latter, and "Ballantyne's remark in 1902 that ante-natal pathology is an almost untilled field is unfortunately almost as true to-day." As regards infant welfare work generally, it is said that such mortality statistics as are available show for the age between 1 month and 1 year a pretty steady diminution from 80.1 in 1910 to 46.7 in 1919.

The Federal Government established a children's Bureau of Investigation in 1912. Its purposes have been widened so that in 1916 it organized a national baby week campaign, and in 1918 a children's year, the aims of the "drive" being public protection of maternity and infancy, mother's care for older children, enforcement of child labour laws and free schooling

for all children of school age, and recreation for children and youth, "abundant, decent, and protected from any form of exploitation." The bureau appears to be a great success.

The United States Public Health Service is also a Federal institution, and has extended its work in recent years. Its traditional practice is to try "to fill gaps"; an example of what this means is found in its action "when the Missouri Legislature created a division or department of child hygiene and failed to appropriate any money to carry it on, or even organize it," a situation which seems to be brought about not very infrequently in the United States. The Public Health Service came to the aid of the State Department of Health with both staff and plans. Various voluntary associations were brought in, all except the largest cities were surveyed as to their child welfare work, including school medical inspection and treatment, nutrition clinics, and the like, so that "to-day practically 100,000 school children are under health supervision in the State of Missouri."

Want of funds, however, does not in some cases appear to be a bar to official action. The Louisiana Legislature refused a request of its Board of Health in 1911 to form a division of child hygiene. In the following year the Board itself took action, and though it had no funds for the purpose it "at once proceeded to publish bulletins of instruction on the hygiene of children and the care of infants," and "in 1913 a health train was utilized for spreading broadcast information and advice regarding the health of the school child." The essential fact is that the work goes on, though it is reluctantly admitted that "of course" activities are greatly hampered by insufficiency or complete lack of funds. Private organizations for child welfare have largely developed, and no fewer than sixty national bodies claim to do such work. The National Tuberculosis Association has also turned its attention to children, and co-operation between the various agencies is being fostered.

Nutrition work for underfed children was begun in New York in 1908, but there and elsewhere has now been extended to the improperly fed. In New York City, where hot school lunches are provided for 3,000 children daily, receipts, it is stated, cover the actual cost of the food; administration and equipment cost 49,000 dollars in addition. In Milwaukee schools milk and crackers are given, and in Seattle any child may receive a bottle of milk a day, but it is not stated whether any charge is made where parents are above the poverty line. In San Francisco certified milk was provided for foundlings to foster mothers and the cost in excess over ordinary milk was defrayed by a local association.

To English sociologists a consecutive exposition of the position in America would be valuable. How far is the system maintained by Federal or State subvention, by local assessment, by voluntary contributions, and by direct payment on behalf of the beneficiaries by their parents or guardians? Details must vary according to circumstances, but a general statement of the lines followed would be very well worth having. Presumably school education and training are freely available for every child, in whatever way the cost is met. But where nutrition is concerned—where there is expenditure on school meals—are parents required to meet the cost in whole or part where they can afford it? Whatever the provision made does it apply only to school attendance days, or also to week-ends and holidays? If a labour strike is declared, do the strikers call on the education authority, as representing the public, to take over the feeding of school children? Generally is it thought in America that parental responsibility is in any degree supplanted or undermined by too easy bestowal of material benefits, or is the system so administered that any such danger is avoided or minimized? No doubt such questions have been discussed and each country might be the better of knowing the facts and the opinions in the other. The children must not suffer—that is axiomatic: but how are the burden and responsibility distributed?

(To be continued.)

THE *Journal of the American Medical Association* for April 22nd contains a special supplement devoted to the amenities of the city of St. Louis, where the annual meeting of the American Medical Association is being held this week, from May 22nd to 26th, and to the preliminary programme of the scientific assembly of the meeting. There are fifteen sections dealing with different branches of medical science, and one section on miscellaneous topics. Each of the sections (with the exception of the last) apparently meets on three days, and each day has a very full programme of papers, discussions, and demonstrations, numbering about a score in each section.

British Medical Journal.

SATURDAY, MAY 27TH, 1922.

PREPARATION OF VACCINE LYMPH.

IN the April number of the *Journal of Pathology* Dr. Myer Coplans adds yet one more to the continually swelling number of methods suggested for the purification of vaccine lymph by the aid of various chemicals. His choice is certain triphenylcarbinol dyes and their leuco-compounds; in other words, malachite green or brilliant green as such, or deoxidized and thus rendered colourless. It is well known that the specific virus of vaccine is more resistant to the action of disinfectants than the concomitant organisms usually associated with it, but experience shows that those chemicals are very few which, while effecting the elimination desired, can with certainty be relied upon not to impair the specific activity.

Coal-tar derivatives have naturally furnished many reagents which from time to time have been suggested for this selective purpose, and it will be recalled that the disinfectant and selective properties of malachite green and brilliant green, as embodied in Loeffler's and Conrad's media, had considerable vogue in the isolation and differentiation of *B. coli*. In this connexion it is interesting to note that the proportion of dye employed by Dr. Coplans—1 in 10,000—for the elimination of all the concomitant organisms is, if we remember rightly, slightly less than the proportion advocated by Loeffler in his medium for the express purpose of enabling *B. coli* to live and flourish.

But Dr. Coplans has other shots in his gun. He brings to his aid glycerin and 0.5 per cent. phenol, and from a table which he gives it would appear that the brunt of the offensive in eliminating the extraneous organisms is borne largely by phenol in conjunction with glycerin. His method is to emulsify lymph pulp with 50 per cent. glycerin in salt solution with the addition of 0.5 per cent. phenol. To this mixture is added malachite green or brilliant green 1 in 10,000. The mixture acquires a high colour, presumably green or blue-green, and, the author states, is rendered bacteria-free in fourteen days, or longer, according to circumstances. But no evidence is given of this. We should have liked to see tables of the bacterial content before, during, and after treatment, indicating the fall of the organisms from time to time; and in passing we may remark that the bacteriological methods employed by the author to ascertain the bacterial condition of the mixture appear inadequate for either quantitative or qualitative estimation.

At this stage a reducing agent in the form of sodium hydrosulphite is added to the mixture. This has the effect of decolorizing the dye-stuff by converting it into its leuco-compound, which the author states has a greatly diminished bactericidal and vaccinicidal action compared with the dye itself. But we note that this decomposition gives rise to products which, according to the author, may in certain conditions act as powerful vaccinicides, "so destroying the potency of the virus."

The condition determining this, he suggests, is excess of sodium hydrosulphite. This state of affairs would seem not unlikely to occur at various points in the emulsion, since the requisite quantity of the reducing agent is added as a powder in one charge directly to the mixture, which the author likens in consistence to condensed milk. Obviously, in these circumstances, the even distribution so as to avoid excess at any point may be attended with considerable difficulty, and if this is so we must assume that material harm may be done to the potency of the lymph.

After this treatment the compound is stored at a temperature of 45° F. to 55° F., which is generally the range of an ordinary ice-chest. The author cites three lymphs treated and stored in this way, and states that they were found to have retained full activity for fifteen months. But, unfortunately again, he gives no evidence of this. We confess that we feel the need of further and definite details—such as, for instance, the number of cases for which the lymphs in question were used, and the results showing personal and insertion success; especially we should wish to see comparative results of lymphs treated by Dr. Coplans's special method and of those (such as issued by the Government) in general use. Very full information is required before exchanging old lamps for new. He states that he has prepared a large quantity of lymph by this method, but he tells us nothing of its use when issued for vaccination purposes, and contents himself with the above meagre statement (confined to three lymphs) of its value. Further, he suggests that his method, owing to its rapidity, will obviate the necessity of storing lymph, and will of itself be sufficient to meet epidemic requirements. We are not clear whether he proposes to do this by a day-to-day output of lymph or by storage of a considerable quantity at the ice-chest temperature he mentions. If the former, it occurs to us that there might be serious difficulty if synchronously with an epidemic there occurred a dearth of animals suitable for vaccination, as happened in the late war, or if the country were swept by foot and mouth disease; if the latter, Dr. Coplans is making a decided regression, and is reverting to the very unsatisfactory conditions of twenty years ago before Blaxall and Fremlin introduced cold storage. In that reversion we do not think he will find lymph experts agree with him. It is well known that it was owing to the system of cold storage that the Government was able to meet the huge and unprecedented demands for lymph made by the rapidly growing armies—their own and others—and these demands were always met promptly and adequately, and, as far as we know, without inconvenience.

We cannot follow Dr. Coplans in his animadversions (and they are not few) on lymph as others make it, but we believe him to be in error if he thinks that storage at suitable temperature involves waste through loss of potency. We understand that no waste whatever is involved and no loss of potency—a marked contrast to former times when lymph was stored, or essayed to be stored, in ice-chests. We gather that Dr. Coplans has had some unpleasant experiences of lymph, for he refers several times to sudden and inexplicable loss of potency in lymphs, and appears to regard this as of common and inevitable occurrence. But we learn that this is not so, that such failures are unknown where lymphs are carefully prepared and stored, and that what seems inexplicable is of simple solution to the lymph expert.

Dr. Coplans invokes State control, and we may recall that the British Medical Association has already made representations to the Minister of Health, pointing out to him that in this country no legal authority exists to enforce the testing of potent and dangerous chemical or biological products. The Minister has appointed a committee to advise him as to the legislative and administrative measures to be taken for the control of the quality and authenticity of such therapeutic substances as cannot be tested adequately by direct chemical means. It might be well to extend the terms of reference of this committee so as specifically to include vaccine lymph, in the hope that eventually some properly defined body may be set up to scrutinize rigorously all curative or prophylactic remedies intended for public use before their introduction to the public, in order to ensure that the claims made on their behalf are just and fully substantiated.

THE PROFESSION AND APPROVED SOCIETIES.

THE Conference of Representatives of Local Medical and Panel Committees, a full report of which appears in the SUPPLEMENT this week, was called specially to deal with a few matters of immediate urgency; one of them is of great importance. The character of the work done by the Conference on May 18th differed from that of most of its predecessors inasmuch as the representatives were concerned, not with changes which they wished to bring about in the arrangements for medical service under the National Insurance Acts, but with an endeavour to maintain those arrangements broadly as they are at present. This would seem to show that the prolonged efforts of the Insurance Acts Committee of the British Medical Association to improve the conditions of medical service under these Acts have achieved a notable measure of success. There are, of course, important points still to be settled, some of which are now in course of adjustment; but there are indications that the stage has been reached when it may be more urgent to resist attack upon the position gained than to seek for an alteration of that position in any fundamental particular.

The main subject of discussion at the Conference deserves the consideration of every member of the medical profession, for it raises matters of far-reaching consequence which may affect both the general question of professional status and the actual conditions under which practice of many types, not merely insurance practice as now conducted, may have to be carried on in the not distant future.

There were grave reasons, based both on experience and on principle, why, in 1911, the profession insisted that "medical benefit" and other benefits of a like nature established under the insurance scheme should be administered not by the approved societies but by Insurance Committees under the direction of a Government department. This point was won; and, unsatisfactory as the composition and position of those committees are in several respects, the committees are at least bodies of a representative character amenable to public opinion and containing, as of right, some medical members. The State has determined that it is part of its business to see that certain classes of workers shall have full opportunity to receive, apart from the Poor Law, such medical advice and treatment as can properly be given by a general practitioner, and has arranged for this by an insurance system which happily at present preserves many of the features of private practice. The Council of the Association and the Conference of Panel Committees have both declared that the measure of success which has attended this system has been sufficient to justify the profession in uniting to secure its continuance and improvement. The terms, financial and other, on which practitioners consent to provide the necessary advice and treatment are settled by negotiation between the Ministry of Health and recognized representatives of the profession, or, in some minor matters, between the local Insurance Committee and the local Panel Committee. The approved societies are now claiming a voice in the negotiations as to the conditions of insurance practice after 1923, and appear to base their claim, curiously enough, on contributions from certain contingency funds towards the cost of medical benefit from April, 1922, to December, 1923—contributions which, after that date, they do not guarantee to continue. These funds do not appear to have been accumulated by any exertions on the part of the societies nor to be their uncontrolled property; nor can the officials of the societies be considered as representing their members on such matters as relate to medical treatment. Even were the reasons for these claims less weak

than they actually are, it would be imperative for the medical profession to maintain the position that the conditions under which it provides treatment for insured persons shall be free from the control of approved societies, and not subject to any negotiations with them.

The exact connotation of the phrase "a voice in the negotiations" is not certain, nor does it seem clear to what extent the Government has conceded any claim; but it is well for the profession to make it evident, as the Conference has done, that though it may be prepared to provide medical services under a State system the general nature of which it approves, and under conditions agreed with the Government as representing the whole community, it will not willingly consent to provide them under arrangements with any unrepresentative or sectional organizations, or under arrangements in which such organizations have any official part. It is to be hoped that it will not be asked to do this.

The essential freedom from even the suspicion of approved society control which was won by the profession on the initiation of the insurance scheme must be maintained in its integrity, not merely for the satisfactory working of the scheme as it stands, but because there is real danger of any extensions of the medical treatment provided (either by legislation enlarging the scope of medical benefit or by the development of "additional benefits" already sanctioned) passing directly or indirectly under the control of approved society officials. This is important to consultants as well as to general practitioners, and in this connexion the constitution and working of the National Insurance Beneficent Association, which certain approved societies have joined to establish, deserves careful attention both by the profession and by the Ministry of Health.

The complications of the National Insurance machinery are known only to those intimately engaged in its working. They are far too great with regard to contributions, benefits, and administration alike. All those who are anxious to reduce those complications, to decrease the waste of energy and money involved in many of them, to help insured persons to obtain easily the full advantages to which they are entitled, and to make the whole social organization work more smoothly, may well hold periodic conferences. We believe that the profession will, like the Conference of Local Medical and Panel Committees, welcome such mutual consultation with a view to these ends. But any development of the present situation going beyond this must give rise to grave misgivings and necessitate united professional action.

SEVENTH CENTENARY OF THE UNIVERSITY OF PADUA.

THE seventh centenary of the University of Padua was celebrated on May 14th to 17th in fortunate circumstances. The weather was fine, but not too hot, and over two hundred foreign delegates attended, about fifty coming from the United States of America, about thirty from Great Britain, Ireland, and the Dominions, and a large number from the universities of Italy. On Sunday, May 14th, the delegates met in the grand hall of the University at 2 p.m., under the presidency of the Rettore Magnifico, Professor Luigi Lucatello; this preliminary ceremony was followed by a discussion on "Scientific synthesis and speculative science, the methods and aims of these researches, and their relation to philosophy." During the day the students organized a picturesque carnival and paraded the streets, as they did on the following Tuesday; in the evening there was a reception at the Casino Pedrocchi. Monday, May 15th, was the chief day of the centenary, as the King of Italy arrived and presided at the solemn ceremony in the Sala Ragione, where, before an audience of five thousand people, addresses were delivered by the Rettore Magnifico, the Sindaco, and Professor Nino Tamassia, and the students sang verses by Giovanni

Bektacchi, set to music by Riccardo Zandonai. The foreign delegates and those from other universities and bodies in Italy handed in their congratulatory addresses, and short speeches were delivered by one representative of each of the nations. The British representative was Sir Archibald Garrod, an appropriate choice, for not only is he Regius Professor of Medicine in Oxford—the oldest British university—but in that capacity a prominent figure in the subject matter of one of the chief faculties of the University of Padua, with which the honoured names of Linares, Cairns, and Harvey are so closely connected. In the evening there was a gala performance of Arrigo Boito's *Mefistofele*, which was attended by the King of Italy. On Tuesday morning Professor Augusto Bonomo delivered an oration on Morgagni, and a large number of honorary degrees were conferred on the representatives of foreign universities, including those of this country, who were well represented in the list and most cordially received. This was followed by a visit to the Collegio Sacra, where more addresses were delivered; the company then made a special train journey to an open-air lunch in the beautiful grounds of the Istituto Idrotecnico (Villa Reale); in the evening a banquet was given to the delegates by the municipality of Padua. Wednesday, May 17th, the last day of the celebration, was occupied by an excursion to Venice. The town of Padua was *en fête* and provided much of interest for the visitors, who were able to study the stemma of William Harvey in the court of the University.

LEPROSY RESEARCH IN BENGAL.

We have from time to time recorded the progress of the researches on the treatment of leprosy by injections of soluble products of chaulmoogra and other oils, introduced by Sir Leonard Rogers, and carried on since his retirement from the Indian Medical Service by Dr. E. Muir in the laboratory of the Calcutta School of Tropical Medicine. It has been decided that the balance of the King Edward Memorial Fund remaining after the cost of the erection of a statue has been defrayed shall be earmarked for medical research, and we are glad to learn that a grant of one and a half lakhs (£10,000) has now been made for research into the treatment of leprosy. This will render possible the erection, on a site opposite the school, of a separate leprosy research laboratory and dispensary where the work may be conducted more conveniently and on a larger scale than hitherto. Dr. Muir is making steady progress with the investigation, and it is already abundantly clear that a number of different oils furnish products which are active in destroying the bacillus of leprosy in the tissues; this opens up the field for research on similar lines on the closely allied bacillus of tubercle. Another very satisfactory piece of news is that the gift of half a lakh of rupees by an Indian gentleman has made it possible to acquire two hundred and forty acres of ground for a leper colony for Bengal in a healthy country area; the Bengal Legislative Council have voted a grant of a similar sum—double the amount the Indian Minister recommended in the present financial stringency—to enable the buildings to be commenced; it is hoped in time to accommodate one thousand lepers, with ample land for cultivation, a cottage system for early cases, a hospital in which maimed patients in an advanced stage may reside, and a distinct part for healthy children. The new treatment has now given such satisfactory results, both in India and in Hawaii, that, for the first time in the history of leprosy, patients suffering from the disease in its early stages are coming forward in numbers and asking for the treatment, instead of hiding their affliction as long as possible to avoid life-long imprisonment without any hope of amelioration of their sad condition. Anyone who is acquainted with the literature of the subject, and the frequent failure of segregation methods on account of the impossibility of finding and isolating cases in the early stages, which are infective through discharge of lepra bacilli from the nose, will realize the immense practical importance in the pro-

phylaxis of leprosy of a treatment which will attract such early cases. It places in the hands of medical men and administrators acting under their advice a great opportunity of carrying out practical measures to reduce, and it may perhaps be hoped eventually to stamp out, this loathsome disease, which in its lingering course spares the vital organs. Bengal may be congratulated on the lead it continues to give to the world in research on leprosy.

THE ETIOLOGY OF TYPHUS FEVER.

We are indebted to the London office of the American Relief Administration for a copy of a report it has received from Dr. Walter G. Davenport, of its medical department in Russia, giving an account of a communication made to the Moscow Medical Society on April 24th, 1922, by Dr. N. Kritch. Since the autumn of 1916 she has been working with Professor Barikan in the laboratory of the Microbiological Institute, Moscow, on the etiology of typhus fever. They have isolated an organism from the brain and spleen of 150 cases of clinical typhus fever one hour after death; they have inoculated 200 guinea-pigs with this organism and have recovered it from every animal. The organism, to which it is proposed to give the name *Microbion typhi exanthematici*, has been found in cultures obtained from over 2,000 infected body lice. It is comparatively scarce in the blood of patients suffering from typhus fever, but exists in great numbers in the internal organs, particularly the brain and spleen, of man and guinea-pig, and in the intestinal epithelium of the infected body louse. It is described as presenting in young cultures the appearance of a disc or biscuit-shaped coccus, varying from 0.4 to 1 micron in length, the breadth being one to two-thirds of the length. It is Gram-negative and is a facultative anaerobe. It does not grow on the usual laboratory culture media, but can be cultivated and kept alive in media composed of a sterilized emulsion of the pancreatized spleen, liver, or intestine of an individual recently dead from typhus; air is excluded by a film of paraffin. Dr. Kritch has also obtained from the brain a luxuriant growth on agar in twenty-four hours; it resembled a culture of the yellow staphylococcus, but died in fourteen to twenty days unless transferred to the spleen medium. Inoculation of guinea-pigs with cultures is followed almost constantly, after a varying incubation period of four to fourteen days, by a rise of temperature lasting six to twelve days. The curve of temperature is said to be characteristic. *Post-mortem* examination of the animals showed passive congestion of liver, spleen, and kidney, and oedema of the brain, with marked proliferation of the lymphoid elements surrounding the small vessels in these organs and some destruction of the intima. The organism was constantly recovered from the brain and spleen of the infected animals. Work on the immunity reactions of this organism has been begun and it is hoped that it may prove possible to prepare a protective vaccine. The American Relief Administration in this country disclaims any responsibility in connexion with the discovery, and we agree that the statements must be received with all reserve. The trend of recent investigations has been to regard a rickettsia (*Rickettsia prowazeki*) as the infective agent.

COCAINE.

Numerous police prosecutions reported recently in this country and in France prove that the illicit trade in cocaine continues on a considerable scale. The chief inducement to resort to the drug seems to be the pleasurable effect immediately produced. The symptoms of mild cocaine poisoning are a feeling of general well-being (euphoria) associated with excitement; the individual feels happy and desires to tell the rest of the world about it, whereas morphine produces a condition of dreamy introspection. The fact that the drug, even in therapeutic doses, may produce sexual excitement has long been known and has been recognized as one of the

disadvantages attending the use of cocaine injections for producing local anaesthesia in dentistry. The effect is not constant, and so far as reported cases go appears to have been observed chiefly in women, from which fact arises the danger for dentists. These two effects—the production of a feeling of well-being, and the occasional aphrodisiac action—may account for the popularity of the drug among the underworld of large towns; by such persons it seems to be taken usually by snuffing into the nose, but self-administration by hypodermic injection is not uncommon. The outstanding features of the cocaine habit are that the majority of the victims are persons under 30 years of age; that a habit is established for cocaine more rapidly than for any other known drug—pronounced tolerance has been produced in eight days; and that cocaine leads to more rapid degeneration, morally, mentally, and physically, than any other drug. The withdrawal of cocaine does not produce any violent physical reaction such as abstinence from morphine causes in a morphinomaniac. Some of the charges against seamen heard at various ports suggest that cocaine is smuggled into this country chiefly from Holland, although probably not manufactured in that country. In noticing some months ago a report on the subject to the Académie de Médecine evidence was quoted tending to show that most of the cocaine sold clandestinely in France is smuggled from Germany. In at least one instance it seems to have been proved that the parcel seized was the manufacture of Merck of Darmstadt. The Bombay correspondent of the *Times*, in a recent telegram, after stating that the cocaine traffic was quiescent during the war, when German supplies were not available, says that extensive smuggling is now again rife. The principal source of supply, he adds, is a German factory at Darmstadt and a secondary factory at Grodno, and it is believed that further supplies emanate from other German laboratories. In such facts as these we have additional evidence that police control of the illicit traffic in cocaine, if it is to be effective, must be international.

ANNUAL MEETING, GLASGOW, 1922.

PREPARATIONS for the ninetieth Annual Meeting of the British Medical Association, to be held in Glasgow at the close of July, are now approaching completion, and we hope to publish in next week's SUPPLEMENT the revised programme of the Sections and a general account of the arrangements made for social functions and other entertainments. The medico-political work of the Annual Meeting opens on Friday morning, July 21st, when the Representative Body of the Association begins its session. The statutory Annual General Meeting takes place on Tuesday afternoon, July 25th. In the evening of that day the President, Sir William MacCewen, will receive overseas delegates and foreign guests, and will present the gold medal of the Association to Sir Clifford Allbutt and to Major Martin Leake, V.C., and the Stewart Prize to Dr. J. C. McVail. He will then deliver his address. The Annual Dinner has been fixed for Thursday, July 27th, and the Popular Lecture, on "The Physician—Naturalist, Teacher, Benefactor," will be given by Professor Graham Kerr, F.R.S., on the following evening. The scientific Sections meet on Wednesday, Thursday, and Friday, July 26th, 27th, and 28th. The Section of Medico-Sociology has now announced that it will devote the day of its meeting, July 28th, to a comprehensive debate on "Alcohol as a beverage, and its relation to certain social problems." At the morning session discussions on "The action of alcohol on the human economy" will be introduced by Professor Mellanby, and on "Alcohol and mental disorders" by Sir F. W. Mott. In the afternoon Professor Edgar L. Collis will introduce the subject of "Alcohol and industrial economy," and Dr. J. W. Ballantyne that of "Alcohol and infantile mortality." The officers of the Section of Tuberculosis announce that at its meeting on July 27th Professor Rist of Paris will open a discussion on the "Clinical differentiation of pulmonary tuberculosis from other respiratory affections," and Dr. James Taylor one on "Some aspects of surgical tuberculosis." In the

afternoon Dr. Rollier of Leysin will give a cinematograph demonstration of heliotherapy. Full details of the programme of these and the other seventeen Sections will be printed next week, when we hope also to publish a descriptive article, with illustrations, on the Medical Institutions of Glasgow.

PHYSIOLOGICAL PROBLEMS IN OBSTETRICS.

THE *Edinburgh Medical Journal* for May, 1922, contains an address by Dr. R. W. Johnstone to the Edinburgh University Physiological Society on "Some unsolved problems in gynaecology and obstetrics." In it he spoke of the dependence of clinicians upon laboratory workers, and indicated some of the many gaps in our knowledge of the physiology of the reproductive organs in women. We were, for example, still in the dark as to the actual cause and precise significance of menstruation, a phenomenon which had attracted much attention from time immemorial. During the last twenty years, however, some real progress had been made; it was founded on the idea that the source of the stimulus which kept the menstrual cycle in motion was the ovary, acting probably along with other endocrine glands. The fundamental fact (demonstrated by, among others, Marshall and Jolly in the Edinburgh Physiological Department) was that the stimulus was blood-borne, not nervous, and the periodicity of menstruation had suggested an analogy with the phenomenon of oestrus or "heat" observed in most mammals. The ovary was even more complicated in the periodicity of its functions than the uterus; the Graafian follicles in its cortex were in various stages of development; each follicle when fully matured ruptured on the surface of the ovary, and the ovum found its way into the Fallopian tube. It seemed not improbable that some internal secretion was formed by the lining cells of the Graafian follicle during the periodic process of maturation and ovulation. An even more curious periodic series of changes followed ovulation; the now empty follicle became a corpus luteum, and much work had been done to test the theory that the corpus luteum was a ductless gland constantly renewed every four weeks. Its retrogression was followed by the rupture of another follicle, which in its turn became a corpus luteum, and so on. There were thus two regular periodic cycles of changes going on in the pelvis of a woman—the first the cycle of ovulation, followed by the development of a corpus luteum in the ovary; the second the cycle of changes in the uterus in association with menstruation. The question arose whether there was a clear parallelism between the menstrual cycle in the uterus and the corpus luteum in the ovary. If there were it would go far to establish the view that an internal secretion from the corpus luteum was directly associated with the cause of menstruation. This, however, was by no means the only interesting problem regarding menstruation which awaited solution. Menstrual blood differed from ordinary blood in certain respects. Blair Bell had shown that it contained a great excess of calcium, and other observers that no fibrin ferment was present. The calcium metabolism in woman was much more unstable than in man; there was evidence that in the female it was governed by the ovary in conjunction with the other ductless glands, and that this control was primarily directed to the needs of reproduction. From the clinical point of view it was of the first importance to get down to the truth in regard to the phenomenon of haemorrhage from the uterus, for menstrual irregularities causing excessive blood loss were amongst the commonest of gynaecological symptoms, and up to the present many of them were treated in a way that was frankly empirical. Another unanswered question was why parturition ensued after a lapse of forty weeks. Experiments had shown that in a uterus severed from all connexion with the central nervous system labour began at the usual time and progressed normally in its motor aspects. The onset of labour must therefore be due to stimulation of the essential ganglia in the uterus by blood-borne substances coming from the ovum itself. There was evidence for the view that the stimulus was either an ovarian hormone or some substance formed

during the altered metabolism of the mother in the later weeks of pregnancy. Remembering the very potent effect which the internal secretion of the posterior lobe of the pituitary had upon the uterus (along with other unstriated muscles), it was impossible to rule that gland out of account. Another promising field for research was the placenta. There were two main views as to the metabolic changes that went on between mother and foetus through the medium of the placenta. So far as the passage of diffusible crystalloid substances like sugar and salts was concerned no great difficulty arose, for this could be explained by a process of osmosis, diffusion, or filtration through the placenta. Much greater difficulty was encountered in connexion with non-diffusible colloidal substances such as fats and proteins; according to one theory the trophoderm had selective powers enabling it to pick out requisite substances from the blood and pass them to the foetus or vice versa. Herein, Dr. Johnston concluded, was material for research with a very important bearing on the welfare both of the mother and of the child.

"GASSED" PLANTS.

THE toxic action of illuminating gas, even in very small quantities, was illustrated by Professor J. H. Priestley, who occupies the Chair of Botany at Leeds, at a meeting of the Association of Economic Biologists on May 19th. Professor Priestley has experimented on the effect of small quantities of coal gas on the growing parts of plants, such as the hyacinth and onion, the pea and bean, and a number of others. If 1 or 2 c.cm. of coal gas are bubbled into a vessel containing the young plant, marked degenerations occur within forty-eight hours. The root and stem structures become swollen and bent, the young leaves curl over, and the flower petals wither. With ethylene, one of the constituents of illuminating gas, the toxic effect has been obtained at a concentration of one in a million in air. Gas in the soil in so small an amount that its presence could not be detected by the smell has proved toxic for roots. Professor Priestley believes that the poisonous action of these small quantities of gas is due to the unsaturated hydrocarbons, which attack the endodermis of the plant. If the "gassing" is carried too far the plants will not recover, but it is possible, by admitting and withdrawing the admixture of gas in the air during the period of plant growth, to get a knotted structure, marked by alternate sections with a normal and abnormal appearance. The investigation has a certain economic interest, in view of possible gas leakages in greenhouses. One curious point is that the gas affects some varieties of the same plant and not others. A speaker in the discussion following Professor Priestley's demonstration mentioned that he had found one variety of chrysanthemum entirely unaffected by a full fumigation with tetra-chloromethane, while another variety was quickly destroyed; the same is true of different varieties of pelargoniums. Evidently botanists are as yet only on the threshold of the study of reaction and immunity in plants.

RICKETS IN THE BRONZE AGE.

A SKULL showing evidence of rickets and believed to be of the bronze age was demonstrated recently to the Cardiff Medical Society by Dr. R. E. Mortimer Wheeler, Keeper of Archaeology in the National Museum of Wales. Only fragments of the skull were recovered, and the evidence of its age is that it was found in a bronze age burial grave some twelve miles north of Cardiff. The date generally accepted for the type of pottery accompanying the skull is between 2000 and 1500 B.C. The remains belonged to a child, probably a boy, about 3 years old, and the cranial measurements were typically brachicephalic. The evidence of rickets seems conclusive. Both Sir Arthur Keith and Professor S. G. Shattock have examined the fragments and have expressed the opinion that the bosses seen on the forehead and on the hinder part of the skull were the result of two attacks of rickets, one occurring when the child was about

6 months of age, and a second about six months later; this was evidenced by the condition seen in the unerupted lateral incisor, which showed two sets of grooves or constrictions corresponding to the periods of the attacks. Dr. Wheeler concluded by stating that the skull afforded the earliest evidence of rickets yet found. In discussing the paper Professor Emrys-Roberts referred to the recent evidence from India pointing to the importance in the etiology of rickets of the deprivation of sunlight and fresh air resulting from the purdah system. In reply Dr. Wheeler gave some account of the mode of life of the bronze age inhabitants of Britain; their huts, he said, were no doubt dark and insanitary, and at the site of the find the climatic conditions had probably been such as to necessitate the inhabitants spending much time under shelter.

KING EDWARD VII SANATORIUM, MIDHURST.

THE fiftieth annual report of the King Edward VII Sanatorium, Midhurst, covering the period from July, 1920, to July, 1921, has just been issued.¹ A postscript printed on the back of the title-page records with deep regret the death of Sir Ernest Cassel, to whose generosity, guided by the wisdom and foresight of King Edward, the institution owes its existence. It was founded in 1903 for educated persons of limited means suffering from pulmonary tuberculosis in an early stage; the buildings were opened in 1906. The council, however, has reason to believe that many patients of this class do not avail themselves of the benefits of the institution, because their medical advisers are unaware of its advantages. It therefore wishes to enlist the co-operation of such practitioners, whose knowledge of their patients will enable them to select persons suitable socially as well as physically for admission. A report of each patient's condition on admission and discharge is sent by the medical superintendent to the practitioner concerned in the case. At present the inclusive charge for maintenance and treatment is 4½ guineas weekly. The buildings stand on high ground on sandy soil at an altitude of 494 feet in one of the most beautiful parts of Sussex; they have a sunny exposure, and are protected from winds. The number of beds is 104, and during the period under review 331 patients were admitted and 269 discharged. Of the 196 patients examined before admission 17.3 per cent. were rejected as unsuitable. The system of treatment adopted is that now common to most modern sanatoriums—namely, an open-air life, regular and ordered routine, a dietary sufficient and nourishing but not excessive, and a system of graduated rest and exercise. In order to secure the intelligent co-operation and confidence of the patients frequent explanatory lectures are given, and, as might be supposed, educated persons make an excellent response. In regard to graduated exercise, a timely note of caution is sounded in the report. Such work when carried out in a sanatorium is not to be looked upon in any sense as a course of education in gardening, poultry-farming, or other open-air work, with a view to employment on discharge. The function of the sanatorium is to treat and arrest the disease, not to teach a profitable employment; to confine the two objects is to invite disappointment; the proper place for technical training is a farm-colony, to which the individual should go after the disease has been arrested at a sanatorium. The laboratory report states that more than 1,000 examinations of sputum were made. Of the 331 patients admitted, the sputum was found positive in 207, and negative in 79; 45 had no sputum. Apart from routine laboratory work, the chief matter investigated was the complement-fixation test for tuberculosis. The technique corresponded closely to that employed by McIntosh and Fildes for the Wassermann reaction. The aim of the investigation was twofold: (1) to ascertain the practical value of the test in the diagnosis and treatment of pulmonary tuberculosis, and (2) to effect technical improvements in order to increase the delicacy and

¹ Copies may be obtained, price one shilling post free, from the Medical Superintendent, the King Edward VII Sanatorium, Midhurst, Sussex.

specificity of the test. In the result 90 per cent. of all cases having at some time had tubercle bacilli in the sputum showed a positive complement-fixation test for tuberculosis, and the provisional conclusion was reached that, on the whole (with the possible exception of certain cases with a positive Wassermann reaction), the test is probably specific, a positive result indicating tuberculous. A positive reaction, once developed, seemed to persist for some time, and there was not usually any change in its intensity during the patient's stay in the sanatorium. No evidence was found to indicate that an obsolete and healed lesion would give a positive reaction, but a positive result was often found in arrested cases. No definite conclusion was reached as to the diagnostic significance to be attached to a negative result with this test.² The annual report contains also summaries of the work of the x-ray and throat departments, together with statistics in tabular form showing the ultimate results of treatment at Midhurst. Much work has been done in the dental department, reflecting the importance attached by the medical staff to the removal of septic teeth and the maintenance of oral hygiene in improving the general condition and resistance of patients with phthisis. Lastly, a brief note states that artificial pneumothorax continues to be employed in a few selected cases with success; the patients come back to the sanatorium to be "refilled," stay the night there, and leave the next day.

"ARCHIVES OF MEDICAL HYDROLOGY."

The first number of *Archives of Medical Hydrology* gives promise of a successful career. It is the journal of the International Society of Medical Hydrology, which was constituted at a meeting held in London at the house of the Royal Society of Medicine in December, 1921, when it was agreed that it was desirable to gather together the scientific resources of this branch of medicine and make them available to the general medical reader. This first number of the *Archives* has a preface by Sir Clifford Allbutt, in which, after an historical summary of the subject, he points out the need in England for carrying higher and higher the new methods in medical hydrology that have been recreated during the last half-century. Establishments, says Sir Clifford Allbutt, which a few years ago were little more than hotels with hydropathic advertisements, are now growing into laboratories of a much higher craft, and it is for science to extract the living kernel of truth from the perishing fruit of experience. Professor Paul Carnot also contributes a short foreword on the scientific aims of hydrology. The *Archives* begins its career, therefore, with high ideals. It may be hoped that the publication of this journal under the editorial direction of Dr. Fortescue Fox will encourage spa physicians to undertake scientific investigations into the action of the remedies with which they deal. To the first number Professor Leonard Hill contributes an article on the effects of heat and cold on the body; Professor Alois Strasser writes on the scientific foundations of hydrotherapeutics; Dr. Wybanw discusses treatment by natural effervescent baths; Professor Chasservant and Dr. Paul Ferreyrolles, Dr. S. Judd Lewis, and Dr. William Bain contribute articles on the scientific study of mineral waters; Dr. Gustave Monod writes on the spa treatment of diabetes; and the editor contributes notes on three pioneers of hydrology—Winternitz, Garrigou, Baruch—who all lived to be octogenarians. Articles written in English are usually followed by abstracts in French, and those written in French by abstracts in English. The new journal is well printed, and the cover design is decidedly interesting; we cannot, however, pretend to like the free use in one of the articles of clarendon type to emphasize phrases and sentences. The annual subscription for the *Archives* is 10s. 6d., post free, and communications should be addressed to the honorary secretary of the society at 36, Devonshire Place, W.1.

² Cf. article by A. L. Punch and A. H. Gosse, *BRITISH MEDICAL JOURNAL*, April 1st, 1922, p. 509.

SIR ALFRED KEOGH.

We mentioned briefly last week that Sir Alfred Keogh was retiring, under the age rule, from the office of Rector of the Imperial College of Science, and Technology at the end of the summer term, and observed that his work there had been sadly interrupted by his recall to act as Director-General of the Army Medical Service soon after the war began. In spite of the interruption, however, the College has under his direction prospered exceedingly, and his enforced retirement is a source of unqualified regret. In 1910 the College was attended by less than 700 students, and there were only 10 post-graduates; the last sessional report shows 1,300 students and 303 post-graduates. During Sir Alfred Keogh's rectorship the college buildings have been greatly extended, and only to-day a new building for the study of biochemistry is being completed and equipped. The teaching posts have been increased in number to an equivalent degree, and talent of the first order has been secured to occupy them. Yet the increased accommodation and provision of teachers has not sufficed to keep pace with the number of students seeking admission, and every year applicants are sent away, even although they reach the prescribed standard of preliminary scientific and literary education. That a member of our profession, after an unparalleled success in his own service, should have again demonstrated his great powers as an administrator in a different and still wider reaching field of national education must be a legitimate source of pride to us all; and while we can but bow to the inexorable rule of superannuation, yet we must deplore that his great work for the College is being brought prematurely to an end. Sir Alfred Keogh has already had a career of extraordinary distinction, of which we gave details in our issues of January 19th, 1918 (p. 101), and March 2nd, 1918 (p. 265). His services in the office of Director-General of the Army Medical Service for two periods were recognized by the Crown when he was created Grand Cross of the Bath in 1917, a distinction reserved for the greatest servants of the Crown, and one which has very rarely been received by a member of our profession. That profession has taken many opportunities of honouring him, and hopefully anticipates that it will in the future have other occasions of expressing to him its indebtedness, not only for what he has done, but for what he will do. Sir Alfred Keogh is in the full vigour of life and capable of rendering many more services to the profession he loves. Its members will not readily forgo their right to make further calls on a leader inspired by its highest ideals, endowed with indefatigable energy, and possessing well-proved powers of organization.

THE Croonian lectures before the Royal College of Physicians of London will be delivered by Dr. Gordon Holmes, C.M.G., C.B.E., on June 8th, 13th, 15th, and 20th, at 5 p.m., the subject being the symptoms of cerebellar disease and their interpretation.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Insurance Practitioners' Remuneration.

MR. ALFRED T. DAVIES, on May 22nd, asked the Minister of Health whether, seeing that the Government entered into an agreement with doctors serving in connexion with national health insurance in 1921, that their remuneration should be fixed, for a period of two years ending December, 1923, at 9s. per insured person per annum, making the total cost of medical benefits 12s. per insured person per annum, that the Minister undertook then that the difference of 2s. 6d. between the sum provided by approved societies and the total cost of medical benefits would be met as theretofore by Exchequer grant, and that it was now proposed to transfer that liability of the Exchequer to the approved societies, he would state the reasons for taking this course.

Sir A. Mond said the undertaking to which reference was made was that no reduction in the remuneration of insurance practitioners should be made during the period in question. No undertaking was either given or asked for as to the source

from which the additional 2s. 6d. would be provided. The Committee on National Expenditure recommended that the Exchequer should be relieved of any charge on this account beyond the statutory two-ninths, the liability being transferred to national insurance funds. The method of securing this result embodied in the bill before Parliament was suggested by the Ministry of Health Approved Societies Consultative Council.

Health Precautions for Miners.

In the course of his speech, on May 18th, on a vote for the Mines Department, Mr. Bridgeman (Secretary for Mines) made some interesting statements as to what is being done for the safety and health of workers in the mining industry.

He said that various committees had considered a good many questions connected with the health of persons engaged in metalliferous mines, and these were being remitted to a small medical committee which had consented to work on matters affecting health in mines, whether coal mines or metalliferous. Another function being carried out by an independent committee under the chairmanship of Lord Chelmsford was the allocation of the Welfare Fund set up under the Mines Industry Act by a levy of 1d. per ton on coal produce. The sum available was about a million sterling, four-fifths of which had to be spent in the localities in which it was raised. Perhaps the most attractive scheme of all was that of the district committee in Ayrshire, which had recommended the allocation of the money, not only this year, but for the whole period of the grant, for the acquisition of a sanatorium for the mining community. They had a fine mansion and one hundred acres of land, and there would be accommodation for one hundred patients in this convalescent home. In regard to the one-fifth of the fund—to be spent centrally—the committee had decided to use it as far as possible for large national work, such as research work or larger questions of education, which went beyond the limits of any particular district. It was proposed to erect a new station for carrying out experiments in coal dust, as well as in testing miners' lamps and in other work which had hitherto been undertaken at Eskmeals in Cumberland. Coming to the services for health and safety, which had been transferred to the Mines Department from the Home Office, Mr. Bridgeman said it was gratifying to find that there were fewer fatal accidents per thousand miners in this country than in any other country except Belgium, and Belgium being so small did not afford a very fair comparison. Even so, he was not satisfied that the accidents could not be reduced very considerably. He did not think it could be done by piling regulations upon regulations; indeed, he believed that an excess of regulations often had the opposite effect, but he was trying to get statistics more easy of comparison. He was thankful to say the department was able to consult a very able small medical committee, consisting of Sir Walter Fletcher, Professor Haldane, Sir Kenneth Goadby, and Dr. Collis. There was also the Mining Dangers Research Board, which was doing valuable work dealing with such questions as nystagmus, miners' lamps, and spontaneous combustion. Under the Privy Council, and not under the Mines Department, there was also a Medical Research Council with which the department was in close touch. This body had consented to consider two or three very important questions. One was stone-dusting. That was as to what kind of stone should, or should not, be used in stone-dusted mines. An investigation was also going on in regard to bent-hand and bent-knee, and several other cognate matters. They had assistance in these research directions from the universities, and also from the organizations for which the owners paid. Mr. Bridgeman went on to say that he was convinced that an immense number of accidents were due to easily avoidable carelessness, and others were due to not having first aid. If it became a habit always to seek first-aid treatment for any scratch or injury many lives would be saved. He was trying to initiate and push a "safety first campaign."

In the course of the debate Mr. Armitage urged that it would be very desirable that the winding engine men in charge of cages should be medically examined at certain periods, and should also have an age limit. On the question of miner's nystagmus he said that in a pit with which he was concerned there were in 1912 about 2,400 men employed. The oil lamps were 1 ear, and white the number of men employed .. the nystagmus cases had gone down to 3. case to the introduction of electric lamps.

Mr. R. McLaren said that in Scotland there were few cases of nystagmus. He had examined many men for it, and found only one or two cases there. In their opinion the reason was that they used open lamps. In regard to the electric lamp he thought that Mr. Bridgeman should seek some means whereby the miner might know the condition of the atmosphere in which he worked. There was said to be an invention whereby, through the ringing of a bell in connexion with an instrument, one could tell the amount of fire-damp present. Many years ago he helped to get an instrument which gave the same results, but it was too delicate.

Mr. Casey protested against the suggestion for medical examination and for an age limit for winders. Speaking as a winder of more than twenty years' experience, he said that the best and safest were not the young men, but men of middle age or whom some would say were of advanced age. He challenged evidence of a single case of serious accident resulting from disability on the part of an engine-winder. He made suggestions for the testing of appliances against over-winding.

The vote was given after two divisions.

Milk Supply, Newcastle-on-Tyne.—Mr. Doyle asked, on May 17th, if the medical officer sent by the Ministry of Health to investigate the serious cases of milk pollution in Newcastle had concluded his task. Sir A. Mond replied that he had received the report of his officer, and was satisfied that the results stated by the medical officer of health of Newcastle-on-Tyne were correct. Mr. Doyle inquired whether the representative was a qualified analyst. Sir A. Mond said he was a qualified man. It was not a question of analysis but of bacteriology. He sent down a medical man, who examined into the bacteriological measures taken. The report confirmed the methods adopted by the M.O.H. as having been satisfactory. On further question by Mr. Doyle, the Minister said he was not aware that since the matter was first raised a fortnight ago additional samples had been taken, and that 10 per cent. additional pollution had been found in these samples.

Accidental Poisoning by Strychnine.—Major Barnett asked, on May 23rd, whether the attention of the Home Secretary had been drawn to a case of strychnine poisoning by misadventure, in which one of His Majesty's judges suggested that mistakes of this kind could be obviated if it was enacted that all poisons should be of definite and distinctive colours; and if so whether he would consider the desirability of issuing regulations under the Poisons Act. Mr. Shortt said he was advised that the regulations for the keeping of poisons direct them to be kept in a room or cupboard "set apart" for the purpose, and that the observance of this rule should in ordinary circumstances render such occurrence impossible. Inquiries were being made of the Pharmaceutical Society as to the practicability of employing definite and distinctive colours for poisons, and if a favourable report was received the possibility of making new regulations under the Poisons and Pharmacy Act would be considered.

Small-pox in the British Army.—Lieut. Colonel Stanley, on May 17th, replying to Mr. Mills, said he was not yet in a position to publish the statistics of small-pox cases and deaths recorded in the British army in various parts of the world during the years of the war. He could not forecast the date of the completion of the statistics.

Disabled Ex-service Men.—The following have been constituted the Select Committee on Government training of disabled ex-service men: Captain Bowyer, Sir Thomas Bramson, Major Cohen, Mr. Colin Coote, Sir John Davidson, Lieut. Commander Dean, Major John Edwards, Major Entwistle, Dr. A. C. Fargherson, Captain Gee, Lieut. Colonel Vivian Henderson, Mr. Lawson, Lieut. Colonel Watts Morgan, Dr. Nathan Raw, and Mr. Frederick Roberts.

Supply of Calf Lymph.—Dr. McDonald asked, on May 17th, if the Minister of Health would consider the advisability of preventing the sale of calf lymph vaccine by any person unless in possession of a Government licence. Sir A. Mond said that the general question of the control of certain therapeutic substances, including the vaccine referred to, was considered by a departmental committee appointed by his predecessor, but the carrying out of its recommendations would involve additional expenditure which the Department was not prepared to undertake at the present time. Dr. McDonald asked if, in view of the alleged increasing inefficiency of vaccination owing to many medical practitioners certifying one vesicle as successful, the Minister would consider the advisability of supplying general medical practitioners with Government lymph at a reasonable charge on the condition that the area produced conformed to that laid down. Sir A. Mond said the matter had been considered from time to time, but as at present advised he did not think it practicable to take action in the direction indicated.

State Management of Liqueur Trade.—Colonel Sir Arthur Holbrook, on May 17th, introduced as a private bill a measure to abolish State management of the liqueur trade.

Rabies near Southampton.—Sir A. Boscawen informed Colonel Barn, on May 17th, it had been necessary to reimpose the muzzling order in an area round Southampton. The origin of the case of rabies near Southampton had not been traced. No other dogs had been infected since the muzzling order was imposed. The dog which was the subject of inquiry was probably bitten some time between early January and May by a rabid dog now dead. Inquiries were being made as to any dog lost or destroyed during that period, and whether any had been smuggled into the Southampton area from abroad.

Criminal Law Amendment.—Mr. Chamberlain stated, on May 18th, in answer to Mr. Thomson, that the Government maintained its intention to pass within the present session a bill amending the Criminal Law Acts.

Illicit Drug Traffic.—Mr. Ramsden asked, on May 18th, whether the Advisory Committee on traffic in opium had reported to the Council of the League of Nations that in spite of the activity of the police and the heavy penalties imposed upon us the traffic in drugs to Western Europe was extremely difficult to check, while it had so far proved impossible to discover the means by which the drugs were obtained or to learn by whom the traffic was organized; and whether, in these circumstances, the Home Secretary would consider increasing the penalties of all convicted traffickers and, if necessary, introduce legislation for the purpose of instituting the punishment of flogging for this offence. Mr. Shortt said that, as he had already stated, the question of strengthening the present Act was under consideration. He added that convictions had been obtained in respect of raw opium, prepared opium, morphine, heroin, and cocaine.

Shepherd's Bush Hospital.—In reply to Mr. M. Wilson, on May 22nd, Mr. Macpherson said that the number of officials and clerks employed at the Ministry Surgical Hospital, Shepherd's Bush, were as follows: 10 medical officers, a controller of stores, an accountant, and 14 clerks. There were also 11 part-time medical officers.

Dangerous Drugs: Farmers and Stock Owners.—In reply to Mr. Hinds, on May 22nd, Sir J. Baird said that licences under the Dangerous Drugs Act had not been issued to agriculturists, but under the order of last August farmers and stock owners in certain circumstances could obtain a certificate from the chief officer of police which enabled them to secure tincture of opium for use in the treatment of animals. No fee was chargeable for the certificate.

ANTI-ANAPHYLAXIS.

LECTURE BY PROFESSOR WIDAL.

ANOTHER lecture of the series by distinguished French medical men, arranged by the University of London, was delivered on May 22nd, when Professor Fernand Vidal, Grand Officer of the Legion of Honour, and Professor of Clinical Medicine in the Faculty of Medicine, Paris, lectured on the subject of "Anti-anaphylaxis." The hall of the Royal Society of Medicine was well filled. In introducing the lecturer, LORD DAWSON OF PENN said that for his researches his name was well known in the medical communities of all nations. On the subject which he had taken for the lecture Professor Vidal and his collaborators had been working assiduously for many years with brilliant success, and many of those present had had the advantage already of reading the results of those researches given in Professor Vidal's lucid style.

Professor VIDAL then lectured for ninety minutes in French in the most vivacious and interesting manner, even investing his abstruse subject with occasional humour. He began by referring to the work of Besredka, who, fifteen years ago, first made known the existence of anti-anaphylaxis by demonstrating that to prevent the anaphylactic shock occurring in a sensitized animal it was only necessary, a very short time before injecting the anaphylactic substance, to give the animal a minute quantity or fractional dose of the same substance. This phenomenon proved that the shock was the result of an overthrow of the colloidal equilibrium of the plasma cells—a condition which he called "colloïdoclasis"—and did not belong to the intoxications, and was not subject to chemical laws. From an observation of many clinical and experimental results, it appeared that the principle underlying anti-anaphylactic vaccination was not special to the state of anaphylactic shock, but appertained to shock of every kind, whatever its origin; nor need the preventive injection be carried out with a substance similar to the one responsible for the shock—other substances very different chemically would answer the same purpose; and the method of administration might be by the digestive tract as well as by hypodermic injection.

For a long time the clinicians had to deal only with accidents following the injection of serum, but serum anaphylaxis was only an example of artificial anaphylaxis, not the spontaneous anaphylaxis of nature. It was not by anything so unrefined as an hypodermic process that the spontaneous anaphylaxis came about. Through the mucous membrane of the digestive or the respiratory tract infinitesimal doses of innumerable substances were daily introduced into the body, and this action, often repeated, might end, in some cases after years, in sensitization to a particular substance. An instance in point was the alimentary anaphylaxis often brought about in infants towards milk or egg, and, again, anaphylaxis by inhalation, which caused asthma. Just as anti-anaphylactic vaccination could be used to prevent accidents occurring on the injection of therapeutic serum, the method being the previous injection of very small doses of the same serum, so the shock in anaphylaxis due to a particular food or drug could be averted in the same way. An attack of urticaria, for example, might be prevented by giving a minute dose beforehand of the alimentary substance concerned in the production of the condition. In cases of alimentary infections where the specific cause could not be recognized, shock might be prevented by the use of ordinary albuminoid substances such as peptone. Even crystalloid substances could be used, an injection of sodium chloride averting the shock consequent upon the injection of serum, and a similar injection or one of sodium carbonate acting in

the same way against the shock following the injection of arsenobenzol in certain subjects.

The lecturer then turned to the question of desensitization. Instead of preventing the anaphylactic shock each time it might appear, all future occurrence of the shock might be prevented in some cases by desensitization. The first experiments along these lines were made in the case of anaphylaxis arising from substances which were digested, and here it was generally easy to discover the responsible antigen. To individuals who had been sensitized by egg, milk, or other such substances, it was easy to give infinitesimal doses of the same substance, increasing the dose progressively each day, and this method had been used in the case of infants. Only in certain cases, however, was specific desensitization capable of bringing about the cure of the anaphylactic condition. Non-specific desensitization also had its part to play; here substances were used quite different from those which brought about the anaphylaxis. In certain cases the ingestion of a very small quantity of peptone an hour before a meal would not only prevent the immediate digestive symptoms of anaphylaxis, but after a certain period would bring about the disappearance of the anaphylactic state of the subject altogether. Desensitization against respiratory anaphylaxis, such as asthma, and hay fever, might be obtained by subcutaneous injection of progressive and frequently repeated doses of the specific substance which was the cause of the anaphylaxis. Anaphylactic asthma was often due to proteins derived from food or animal products, and vaccination with the specific protein might make the asthma disappear, at least for a time.

Finally the lecturer touched upon symptomatic treatment of the shock, instancing the results obtained with adrenaline, atropine sulphate, and other substances. He spoke also of disturbances of the endocrine glands from this point of view, mentioning that asthma could be favoured in its development and regulated in its cycle by functional study of the ovary or thyroid, and with the conditions created by endocrine disturbances one could watch the development of anaphylactic hypersensitivity to certain imponderable things which brought about the attack of asthma. Altogether the physician had a variety of means of dealing with anaphylactic manifestations. All these on occasion had had remarkable success, but there had been also conspicuous failures, and in the presence of the anaphylactic condition the physician never knew in advance which therapeutic measure would succeed. It was necessary to be very patient and to try successively the different procedures, not forgetting the unexpected success which some of them had given in cases which up till then had defied all treatment.

Sir ALMROTH WRIGHT expressed in French the thanks of the audience to Professor Vidal, and went on to say that Professor Vidal had confessed that he was *passionné* with this subject. For his own part, whenever he went to Paris and wanted to get "impassioned" with some intellectual interest, he betook himself to Professor Vidal's laboratory and always found something new. Professor Vidal, although a great clinician, did not content himself with clinical methods. He did not say that what he could see with his eyes and hear with his ears was all that there was to be known. He had introduced into medicine a new physical method of experiment, and if medicine was to advance it must be by the use of such laboratory methods. Although Professor Vidal was in the first place a clinician, he was not content to use other laboratories and other men, but worked assiduously in his own laboratory. The adoption of the experimental method did not mean that the experimenter was going to try anything upon anybody; it postulated a scientific training, and one saw that certain things which had been tried in the laboratory might with advantage be carried out in practice. The experiments were not made at random. Professor Vidal was also great in his power of generalization; the test of a great man was to make proper classifications of things. For his insistence upon laboratory experiment and for his power of generalization his British colleagues held him in all honour.

Dr. GRAHAM LITTLE rather contested Sir Almroth Wright's inclination to group Professor Vidal among the men of the laboratory; to him he was the supreme physician. The University of London had done a very great service in introducing these distinguished French professors to the British medical world. This country had been too long under the influence of the Central European system of medicine, and one result of the war had been to make its medical men better acquainted with the Latin system, to their great advantage.

England and Wales.

A RED CROSS CIVILIAN CLINIC.

LAST year the work of the clinic founded by the Kensington Division of the British Red Cross Society for the treatment of ex-servicemen began to diminish, and it was recognized that within a short time there would not be enough patients to justify its maintenance. The functions of the clinic included treatment, with massage, electricity, radiant heat, and remedial exercises. After consultation with representative local medical practitioners, including the Mayor of Kensington (Dr. A. J. Rice-Oxley), it was decided to institute a clinic for the general public. This new clinic was opened in Kensington last February, and now between thirty-five and forty patients are attending it weekly. Its object is to put physical treatment within reach of those members of the civilian population whose financial position is such that they cannot afford the ordinary fees charged. A patient is requested to bring a letter of recommendation from his own doctor, and before any treatment is given he is examined by a specialist in physiotherapeutics, who attends the clinic on Mondays and Fridays at 6 o'clock. Medical practitioners are requested not to send patients able to afford higher fees than the maximum charge at the clinic, which is 5s. for each treatment and 5s. for the consultation; an almoner is in attendance on the evenings of Mondays and Fridays, and individual charges are decided by the almoner, and referred to the committee for revision if necessary. The clinic is administered by the Kensington Division of the British Red Cross Society, which bears any financial responsibility and works in conjunction with an advisory committee of medical practitioners. The scope of the work is very varied. It comprises the treatment by physical methods of all forms of injury or disease of the limbs; of sprains, fractures, dislocations, stiff and painful joints, and of cases in which muscle power has been for any reason reduced or lost. Post-operative treatment is also undertaken, as are appropriate cases of neuritis; and patients suffering from postural deformities, deficient chest expansion, and under-nutrition. The re-education is undertaken of patients suffering from various disorders of the central nervous system; from neuralgia to talipes dorsalis; instruction is given also in the use of an artificial leg, and patients are provided at the clinic with the more simple orthopaedic appliances, such as special boots and splints. Patients living in Kensington have a prior claim on the clinic, but should there be vacancies applicants living outside the area are accepted. The Kensington Division of the British Red Cross Society deserves credit for its endeavour to provide, in conjunction with the medical profession, this physical treatment centre. Such clinics are needed, and the lines upon which the centre at Kensington has been established and developed may serve as an example to others.

TUBERCULOSIS CARE COMMITTEES.

The Ministry of Health has circularized the metropolitan borough councils with regard to the organization of voluntary care committees in connexion with tuberculosis dispensary schemes. Since 1915 this work has been carried out on a provisional basis, but the present time is believed to be opportune for the establishment of permanent committees. The circular offers suggestions for the guidance of borough councils in this respect. As many members of the committee as possible should be experienced in social welfare work, and a representative of the local war pension committee should be included. A responsible secretary should be appointed whose work should include the preparation of information for the use of the committee. The unit with which the committee should concern itself is the family, not the individual patient, and the economic position of the family is to be considered as an important factor in the problem. It is not the function of the committee directly to provide financial assistance except as a temporary expedient in special cases, but the family should be brought to the notice of the appropriate charitable or public organization. Close co-operation must be preserved between the committee and the staff of the dispensary. The tuberculosis officer should regularly attend the meetings of the committee to advise on the medical needs of cases and to inform himself of the measures taken by the committee in the economic interest of the patients. Other functions of the committee are to undertake the assessment of charges made in respect of residential treatment where the income of the family exceeds a certain amount, and to

investigate cases in which the provision of extra nourishment or dental treatment is recommended by the tuberculosis officer on medical grounds. It is urged that the meetings of the committee or of a responsible subcommittee should be held weekly.

ROYAL BATH HOSPITAL, HARROGATE.

The Royal Bath Hospital and Rawson Convalescent Home, Harrogate, was reopened on April 20th, considerable improvements having been carried out in its equipment. The bath-house has been reconstructed and a new cooling room formed, and the interior of the hospital has been reorganized so as to provide additional rooms for the nursing staff. The alterations to the bath-house include a granolithic floor, a new douche room, as well as a room for Berthollet and paraffin wax baths. The white porcelain slipper baths have been screened according to a new scheme and are slightly sunk in the granolithic floor to facilitate cleaning. The douche room is fitted up so that treatment may be given either by the Aix or Vichy method, and in addition to the needle bath a "Scotch douche" has been installed. The bath-house has now three local steam or Berthollet baths, and also paraffin wax baths for the knee, hand, and foot. What remains to be done before the completion of the proposed scheme is to build a small Plombières department, an efficient clinical laboratory, new massage and electrical rooms *en suite* with the bath house and cooling room, and an x-ray operating theatre and examination rooms. These additions are required to make the hospital a complete modern centre for the treatment of the rheumatic and arthritic groups of diseases, and some £7,000 are necessary to carry them out.

LIVERPOOL LADIES' SANITARY ASSOCIATION.

This association, now of some years' standing, continues to do excellent work in promoting infant welfare by affording ladies of leisure the opportunity of undergoing a training enabling them to perform useful work for the public advantage. The Ministry of Health approved of the object and has given financial assistance. Recently a new departure has been made, for it was felt that an observation nursery for delicate children would meet a great need in those cases where the mothers were incapacitated from giving the necessary attention to such children. Further, the children's hostels provided opportunity for training elementary school girls who desired to become competent nursery maids. The medical officer of health, Dr. E. W. Hope—who has been connected with the association from its beginning—has borne testimony to the good work that has been so quietly and so perseveringly performed; the municipal health and education authorities are, he says, fully alive to its efforts for the health of the young life of the city. The financial statement shows a deficiency of £1,100, and the Lord Mayor has made an earnest appeal for subscriptions to an association whose good practical work is apparent to all.

Scotland.

EDINBURGH POST-GRADUATE COURSES.

Courses for medical graduates will be held this year in connexion with the University and Royal Colleges of Edinburgh from July 31st to September 9th inclusive. They will comprise: (1) A course in diseases of children, from July 31st to August 12th, the fee for which is six guineas, or five guineas for those attending either of the general courses; (2) a general medical course; and (3) a general surgical course. Courses 2 and 3 will each last four weeks, from August 14th to September 9th; the composite fee for each is ten guineas for the four weeks, or six guineas for either the first or the second fortnight. A series of special lectures open to all graduates will be delivered three times a week during the month on subjects of general medical and surgical interest, including recent advances in treatment. A number of special courses have also been arranged for the summer term (May to July) and the autumn term (October to December). Particulars may be had on application to the Honorary Secretary, Post-graduate Courses in Medicine, University New Buildings, Edinburgh.

MEDICAL SOCIETIES OF GLASGOW.

The annual business meeting of the Glasgow Royal Medical-Chirurgical Society was held on May 5th, when office-bearers for session 1922-23 were appointed as follows: President,

Dr. A. Maitland Ramsay; Vice-Presidents, Dr. R. O. Adamson and Dr. G. Morris Crawford; Secretary, Dr. Adam Patrick; Editorial Secretary, Dr. G. Herbert Clark; Treasurer, Dr. James H. Martin. Now councillors were appointed in the various sections: Medicine, Dr. John F. Fergus; Surgery, Mr. James Russell; Pathology, Dr. J. Norman Cruickshank; Obstetrics, Dr. Donald McIntyre.—The Glasgow Northern Medical Society has appointed the following office-bearers for the ensuing session: President, Dr. Robert Grieve; Vice-Presidents, Dr. P. McKellar Dewar and Dr. A. M. Crawford; Secretary, Dr. A. Stanley Richmond; Treasurer, Dr. James H. Martin.

EDINBURGH ROYAL MATERNITY HOSPITAL.

The annual meeting of the Edinburgh Royal Maternity Hospital was held on May 19th; Lord Provost Hutchison presided, and among those present were Dr. T. G. Nasmyth, the newly elected Chairman of the Board of Directors, Emeritus Professor Sir Halliday Croom, Sir Ludovic J. Grant, Bt., and Sir Robert Maule. The report showed that the number of women delivered in the hospital, at their own homes, and at the Leith branch during 1921 was 2,770; this was 176 fewer than in 1920, but it was far above the total for any other year, and further the number of cases confined in the hospital itself showed an increase of about 100. The number (2,770) was about 30 per cent. of all the births in Edinburgh and Leith during 1921. The number of beds for mothers in the institution was now 93. The report further indicated increased attendances both at the antenatal clinics and in the venereal diseases department. The new cases at the antenatal clinics numbered 816 and the revisits 1,582; at the V.D. clinics the number of new cases was 138 and of revisits 1,053; and 150 deliveries had taken place in the V.D. department. The Lord Provost, in his speech, referred to these numbers and reminded the audience that the hospital rendered valuable service in connexion with the maternity and child welfare services conducted by the Public Health Committee of the Town Council and also in the treatment of venereal diseases, which was another development of municipal public health activity.

CHILD WELFARE INSTITUTE FOR SCOTLAND.

Reference was made in the JOURNAL of April 22nd (p. 658) to a conference held in Edinburgh in regard to the establishment of a child welfare institute for Scotland, for the establishment of which the trustees of the Carnegie United Kingdom Trust had offered £40,000. A draft constitution and scheme of organization presented at that conference provoked considerable discussion and criticism. Professor Munro Kerr of Glasgow said that he believed that it was not possible to conduct an institute of the kind on £1,500 a year, as had been said, and contribute anything to science. The other medical representatives who were present took no part in the discussion, which was mainly financial, but there was a free expression of opinion among them that the objects sought or in the institute might be obtained by a strengthening of existing resources. On May 17th a subcommittee of the Edinburgh Town Council considered a letter from the secretary of the Carnegie United Kingdom Trust stating that the trustees had come to the conclusion that the proposals submitted were not upon the lines which they contemplated when the offer of £40,000 was made; they were of opinion further that the financial prospects of the scheme submitted were far from satisfactory, and intimated that the original offer of £40,000 was now withdrawn.

ROYAL ALEXANDRA INFIRMARY, PAISLEY.

Large extensions are to be made to the Royal Alexandra Infirmary, Paisley, by the trustees of the late Mr. Peter Coats of Paisley, and it was stated at the recent annual meeting of the infirmary that the expenditure would amount to "several tens of thousands of pounds." The proposed extensions comprise six blocks of buildings, including three two-story blocks consisting of ward sisters' rooms, a block containing an electro-cardiograph department, another devoted to doctors' and nurses' dining-rooms, etc., and an important block containing two large electrical rooms, waiting-rooms, new operating theatre, and other accommodation; two new massage rooms are also to be arranged for separately.

CENTRAL MIDWIVES' BOARD.

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, there were 103 successful candidates out of 112 who submitted themselves for examination. At a

special meeting of the Board for the hearing of penal cases three midwives were cited for various breaches of the rules, and were found to be generally incapable of carrying them out; their certificates were directed to be cancelled and their names removed from the roll. In the case of another midwife found guilty of breaches of the rules sentence was postponed for reports from the local supervising authority, at the end of three and six months respectively, regarding her conduct and methods of practice in the meantime. Failing satisfactory reports being received, her name was instructed *ipso facto* to be removed from the roll.

Correspondence.

STATISTICS OF PUBLIC HEALTH.

SIR,—In his interesting third Milroy lecture, published in your columns on May 13th, Dr. Greenwood attributes to me the opinion that the statistician's "place is in the propagandist rather than in the research department of the public health service."

It is always difficult to summarize another's opinion or argument without quotation, and on this occasion Dr. Greenwood has failed to express accurately my stated views, thus making it desirable to ask you to insert the following quotations from the American address to which he refers:

"In their present stage of development in most communities vital statistics form an excellent servant but a bad master for the health officer. They have been invaluable in stimulating [it may be by propaganda] "and in guiding public health effort, especially in directing attention to the areas of excessive mortality" [this is research followed by attempts at administrative control].

It is true that I then proceeded to warn against conclusions based on statistics of general and constitutional diseases, view of the imperfections and changes of medical certification, and added, "we need to bear in mind the necessary limitations of statistical inferences." I cannot, I assume, ask you to insert my entire paragraph on infant mortality from the *Journal of the American Statistical Association*, while Dr. Greenwood has not succeeded in summarizing accurately but it appears necessary to quote the following extract from that paragraph:

"Did we possess quantitative knowledge of the value of each factor influencing infantile health and disease, and were we able to measure the extent of action of each factor, it would be possible to assess the relative importance of each factor concerned in producing or preventing infantile sickness and mortality. But we usually cannot do this."

Apart from the last short sentence of this quotation, it appears to coincide with Dr. Greenwood's own views.

I welcome the opportunity to make this statement, as it gives me the occasion to emphasize the real burden of the remarks to which Dr. Greenwood alluded. "Statistics can have no greater value than that of the data on which they are based, however skilfully they are used, and if statistics of dubious quality point in one direction and physiological and pathological knowledge in another, the health officer will have no doubt as to his right road. No one reading carefully my address will fail to appreciate the great importance attached in it to the intensive study of vital statistics for research in the hope of improving administration, and not primarily for publicity purposes.—I am, etc.,

Shalford, Surrey, May 15th.

ARTHUR NEWSHOLME.

"ALASTRIM" OR "PARASMAILPOX."

SIR,—I thank Dr. Garrow for the courtesy of his letter which appeared in your issue of May 13th (p. 780). I am not sure, from a perusal of it, whether he considers "alastrim" a separate disease or merely a variant of small-pox. In the second paragraph of his letter he distinctly states that it is a separate entity, but in the last paragraph he seems to refute this, and suggests that the real nature of the disease is still in doubt.

An article by W. C. Rucker, M.D., of the United States Public Health Service, which appeared in the *Medical Officer* of January 28th, 1922, gives a lucid and succinct description of "alastrim." In that article the writer defines the disease as "an acute febrile, easily communicable disease, closely resembling small-pox, as a mitigated aberrant form of which, from a public health standpoint, it must be regarded." Again and again throughout the article the author reiterates his

conviction that the disease is merely a variant of small-pox; and when he comes to diagnosis he makes the significant statement: "From the viewpoint of public health, 'alastrim' should always be diagnosed as small-pox." Judging from the description given in the article, "alastrim" so closely resembles small-pox in all its clinical characteristics that to make a differential diagnosis between the two would be a matter of extreme difficulty.

In addition to this clinical similarity, the diseases are said to resemble each other in their reactions to vaccination. A note appended to Dr. Rucker's article gives the results of certain inoculation tests undertaken in the United States by Leake and Force, which seem to prove that the two diseases affect monkeys and rabbits in a manner entirely similar. The last paragraph of the note gives the conclusions of the two workers and reads as follows: "The fact that definite immunity to vaccinia is produced by previous inoculations with 'alastrim' is additional evidence of the essential identity of 'alastrim' with small-pox."

I cannot see that Dr. Garow is entitled to draw an analogy between "alastrim" and paratyphoid fever, because whilst a definite etiology has been worked out for the latter, that of the former, as of small-pox, is still obscure.

With such conclusive evidence of the identity of the two diseases, there seems to be no good reason why we should continue to recognize "alastrim" as a separate disease and accord it a distinctive designation. The dictionary of medicine is sufficiently confounded already with names without adding others which are entirely superfluous. This is not a time for confusing issues; rather is it a time for clear thought and direct action, because knocking at the nation's door at this very moment is what may prove to be one of the most serious epidemics of small-pox which has ever assailed the population of these isles.—I am, etc.,

J. JOHNSTONE JERVIS.

Leeds, May 17th.

ETIOLOGY AND TREATMENT OF DIABETES.

SIR.—Dr. Renshaw and Mr. Fairbrother appear to have missed the point of my criticism. In any investigation into intestinal fermentation it surely is of prime importance to take into consideration the dietetic history of patients and controls. These essential clinical facts are neglected by them. It is easy to show by an example how erroneous may be any conclusions formed by examination of the faeces alone. For example, if we feed tuberculous patients on raw meat we find that tapeworm infection is very common amongst them and tapeworms are recognized in the faeces. If now an observer discovered tapeworms in 60 per cent. of tuberculous patients and in no controls, would he be justified in suggesting to a learned profession that tapeworms were the cause of tuberculosis? Yet he would have just as good reason as your contributors have for assuming the etiological rôle of *B. amyloclasticus*. The necessity for detailed dietetic histories is emphasized by this example, because the tapeworms would persist, if untreated, long after the patient had resumed normal diet. Categorical statements without such details are of no value, and I suggest that it is very unscientific to omit them from the article in order not to obscure the "presentation of the more scientific details." The whole essence of scientific experiment is that the conditions are controlled. In this case it is evident that the conditions were not controlled as regards that most important item in intestinal fermentation—namely, diet.

This is an unfortunate divorce of clinical medicine from the laboratory. It only tends to increase the "big, booming, buzzing confusion" which surrounds the subject of diabetes, and which Allen claims, with justice, to have helped to dissipate. The other points raised are of minimal importance in view of the lack of control.—I am, etc.,

A. E. BARNES.

Sheffield, May 21st.

SIR,—I have certainly not had the opportunity of seeing the results of fermentation *in vitro* of pure cultures of *B. amyloclasticus*, but I am quite ready to accept the statement made by Dr. Renshaw and Mr. Fairbrother, that certain intestinal organisms exercise beneficial restraining influences over the vigorous action of that bacillus. It is, I believe, owing to a deficiency of such organisms in the intestinal contents that they have been able to isolate *B. amyloclasticus* with comparative ease from the faeces of patients suffering from diabetes. This deficiency probably arises from the alterations in the digestive processes which occur in diabetes.

It has long been an established fact that the character of the intestinal flora is largely dependent upon the nature of the food in health, and that in disease it is also modified by variations in the secretions of the alimentary tract and by the extent to which the digestion of various food materials is interfered with. The examinations I have made during the past fifteen years of hundreds of specimens of faeces from all types of glycosuria and diabetes have shown that definite chemical alterations in the intestinal contents occur which would account for the presence of an abnormal flora. Certain of these alterations are found in all cases of typical diabetes, and probably explain why a particular type of organism should be a constant feature; others occur only in certain types of glycosuria, but are characteristic of that type. At one time I carried out extensive bacteriological investigations on the faeces in diabetes and only abandoned the work when I satisfied myself that the variations from the normal that were found could be explained in the manner indicated.

Although it is true that Koch's postulates have not been satisfactorily complied with in every disease in which the etiological agent is known, failure has always been due to special conditions, and it has usually been only after repeated unsuccessful attempts that the agent in question has been accepted as the causative factor on overwhelming clinical and experimental evidence of other kinds. The mere fact that scientific proof is costly or laborious is hardly a valid excuse for no attempt being made to fulfil established conditions of research, and for the premature publication of incomplete observations. Had Dr. Renshaw and Mr. Fairbrother confined their paper to a statement of the facts they have observed, and been content to draw attention to the striking similarity of the substances produced by the fermentative activity of *B. amyloclasticus* to the abnormal products occurring in diabetes, no exception could have been taken to it; but when they proceeded to "cut the Gordian knot of diabetes" with an imperfectly tempered knife forged from a diminutive amount of material, and claimed to have solved at one blow a problem which has occupied the attention of numerous experienced observers and experimenters during the past half-century, it became necessary to ask for rigid proof of such a claim.

It is an easy way out of a difficulty to avoid the facts that do not fit in with one's preconceived views; but I think that if Dr. Renshaw and Mr. Fairbrother will "ruminate" upon the questions, which they have not attempted to answer, raised in my previous letter, and will also consider the evidence that diabetes is not a disease, but a symptom complex which can be produced in a variety of ways, they will realize that the problems of its etiology and treatment are not as simple as they appear to imagine.—I am, etc.,

P. J. CAMMIDGE.

London, W., May 20th.

"SYMPTOMLESS HAEMATURIA."

SIR.—In Mr. Burgess's excellent lecture on symptomless haematuria, published in the *JOURNAL* of May 20th, there is one point upon which he touches about which it would be interesting to get further information. I refer to positive evidence on microscopic examination of the urine in cases of renal tumour. In what percentage may such evidence be expected?

In two cases recently under my care—one of a malignant papilloma of the renal pelvis, with a small secondary deposit in the cortex of the kidney, and the other of a carcinoma of the upper half of the kidney involving the pelvis—microscopic examination of the urine revealed the presence of groups of epithelial cells, presumably of neoplastic origin. In both these cases haematuria was the only symptom, and cystoscopic examination was the only means of determining the site of the lesion, no enlargement of the kidney being discernible even under an anaesthetic.

Can reliance be reasonably placed on the presence and character of such epithelial cells in the urine sufficient to justify (1) a positive diagnosis of tumour; (2) a diagnosis between a malignant tumour and a simple papilloma? If so, then in such a case when a diagnosis of malignant renal tumour has been made, although the kidney on inspection may reveal no confirmatory evidence, it is surely better to do a primary nephrectomy rather than a preliminary exploratory nephrotomy, with its attendant risk, slight though that may be, of implanting malignant cells in the tissues of the wound.—I am, etc.,

Norwich, May 22nd.

A. J. BLAXLAND.

DETOXICATED VACCINES.

SIR,—I observe that Dr. David Thomson (p. 796) attributes the toxicity of "detoxicated" or residual vaccines to the presence of a small amount of "unaltered toxic germs."

A few months ago a certain commercial concern issued broadcast a pamphlet dealing with these vaccines in which they were pleased to notice my work and to seal it with their approval. The anonymous author then proceeded to state that it was easy to see why I had reported that toxic effects could be produced by these vaccines—the imperfection of my method of preparation allowed a small number of unaltered germs to escape detoxication. This admirable clarity of vision is not vouchsafed to us all.

Twelve months ago I published in this journal an account of the vaccines, and pointed out that many of the organisms do not dissolve but swell in an alkaline solution and contract in an acid, from which one may infer that water can pass through the cell membrane. Such being the case, it is absolutely certain that nascent oxygen can do so. The action of this last substance was described.

I also showed that a residual vaccine heated in the autoclave was every whit as potent as one which had not been heated—a fact which disposes of the contention that thermolabile substances such as toxins are present in an autoclaved vaccine, and necessitates a search in some other direction to find the cause of the toxicity. My method of sterilization is based upon this resistance to heat, and enables one to use the safe and certain method of steam under pressure—namely, fifteen minutes' exposure to a temperature of 120°C. If the "unaltered germ" theory of toxicity is correct it follows that many of the common non-sporing bacteria are unaffected by this degree of heat. The patent absurdity of this needs no elaboration.

There is ample evidence that many bacterial substances, other than exotoxins and endotoxins, are toxic, but there is none to show that the products of bacteria can produce immunity against the whole organism and be at the same time absolutely non-toxic. The fact that they may act as efficient antigens proves nothing. I never heard that cholesteriolized heart muscle was either prophylactic or curative in syphilis.—I am, etc.,

Manchester, May 20th.

C. E. JENKINS, M.R.C.S., L.R.C.P.

NITROUS OXIDE AND OXYGEN.

SIR,—Dr. Holme Henderson's paper on this subject read before the Scottish Society of Anaesthetists and reported in the JOURNAL of May 13th (p. 763) will, I trust, revive the enthusiasm which the success of this method of anaesthesia in France and at military hospitals at home provoked in 1917 and 1918.

The current misconceptions about nitrous oxide and oxygen as a general anaesthetic are mainly of two types. According to some surgeons it gives unconsciousness, but not the relaxation needed for most abdominal work; other operators say the same, but add that when it does it is merely when employed as a camouflage for ether or chloroform.

As an anaesthetist and a patient I venture to agree fully with Dr. Holme Henderson's conclusions—namely, that any case, even a gall bladder case, can be successfully anaesthetized with it, though, of course, occasional blowing over or through ethanasal may be needed. I can with emphasis bear testimony to the unpleasant after-effects of ether and the difference when I had nitrous oxide and oxygen with a little ether. My experiences are still vivid, so sympathy for all fellow creatures who may have to take an anaesthetic makes me urge its extended employment.

Figuratively, nitrous oxide and oxygen may be said to have got over the footlights, in spite of the spectre of want of relaxation, notwithstanding even, perhaps, the lack of skill of some of its early administrators. There is no doubt that even the wisdom of Solomon can be made to look like folly by the accident of failure.

As the writer of the paper says, a proper apparatus is needed, with sight feed and fine adjustment valves, so that there is absolute control of the amount of oxygen and gas and a means of at will blowing over or through jacketed ethanasal. Geoffrey Marshall's apparatus has the advantage of portability. I usually employ one I made in 1917; it was described in the *Lancet* of July 13th, 1918, and shown previous to that at the Royal Society of Medicine.

A preliminary narcotic of morphine and atropine, warming the gases, and bubbling over or through ethanasal adds greatly to the success; a very little of the latter is, as a rule, re-

quired. Of course the last word has not by any means been spoken: if the *plus* pressure theatre advocated by Dr. Leyton is provided, the good nature with which this method is now received will be absolutely without the slice of lemon that is noticeable among some of its unamiable critics.—I am, etc.,

CHARLES T. W. HIRSH, M.R.C.S.,
Anaesthetist, Samaritan and other Hospitals,
London, S.W., May 15th.

THE GENERAL PRACTITIONER AND THE HOSPITALS REPORT.

SIR,—I am still unable to discover in the Hospitals Report a definition of the word "voluntary." In fairness to the Chairman of the Hospitals Committee I shall quote paras. 6 and 7.

"6. The Association records its belief that the voluntary method of administration of the voluntary hospitals of the country is to the advantage of the public, medical science, and the medical profession, and that it should be maintained."

"7. The Association maintains that the essence of the voluntary hospital system is the independent and voluntary management and that this is not necessarily related to the conditions of service of the medical staff."

Mr. Harman asks what is to be said to those who assert that these paragraphs are too definite, and I quite sympathize with him in his difficulty in answering these objectors.

It may be that more hangs or will hang on the interpretation of the word "voluntary" than is contemplated at the moment. For instance, what is to prevent an approved society or association of societies from opening a voluntary hospital for its members? After all, we are much more concerned with the conditions of service of the medical staffs, to which "it is not necessarily related."

With regard to contract practice Mr. Harman has entirely missed the point. It is not that hospitals will undertake the insurance risk of hospital benefit, but that the staffs will. Para. 22a states that—

"payments for tariff patients should be for work done based on a tariff of fees, making full allowance for . . . payment of medical staff."

May I ask what a typical tariff would be like? Would it, for instance, give varying fees for different operations or the fee per visit of the "honorary" physician? If it is a "work-done" tariff it certainly ought to, but I can hardly imagine that this will be the case. It does not matter, however, because para. 33 nullifies the tariff by stating that—

" . . . a percentage of all such payments should be passed into a fund which is at the disposal of the honorary medical staff."

If this is not contract practice it is something worse. Mr. Harman meets my contention that contracts and tariffs are to be made by hospitals without consulting the staffs by saying that para. 39 provides for representation of the profession on the management. It does not. It merely says that it is desirable, and even if there were representation that is not enough. The British Medical Association exercises the right to approve or disapprove of remuneration in every other department of public practice and it most certainly should retain that right in this department.

Mr. Harman will forgive me for complaining that the bulk of my criticism is still unanswered, and for his and others' benefit I shall repeat it categorically.

1. The hospitals are to be no longer voluntary in the sense that they are entirely supported by voluntary contributions.

2. They will open their doors to persons with incomes up to £350 per annum, persons who can, either directly or by insurance, pay an adequate fee for treatment.

3. They may make financial arrangements with public bodies of all kinds for the services of the medical staff.

4. There is no provision for adequate remuneration for such services.

5. Patients may be admitted under financial arrangements who might as well be treated at home or in an institution which has not made a financial arrangement.

6. Free choice of doctor for tariff patients is not even considered.

I maintain that this scheme constitutes unfair competition with private practice, both general and specialist, and its adoption by the British Medical Association would be a grave blunder.—I am, etc.,

Bury, Lancs., May 21st.

J. C. TURNBULL.

ASYLUM METHODS.

SIR,—In a recent article you published the recommendations made to the Board of Control by a subcommittee chosen from the members of the Quaker Medical Society. May I go a step farther back and recall the remarks recorded in the annual report of the said Board for the year 1920,

on an inquiry by three of the Commissioners in respect of allegations made concerning certain asylums by four attendants, and made public in the journal *The Friend* of May 23th, 1920? The inquiry took place on September 13th, 1920.

This investigation was perhaps unique as regards such inquiries in that the witnesses were not patients whose evidence could be brushed aside as "delusory," but free and independent men who had had exceptional opportunities of becoming acquainted with the interior of asylums.

The allegations, as set out in the Board of Control report, were as follows:

1. That the medical attendance, supervision, and treatment were most inadequate; that the classification of patients was imperfect; that there was no segregation of tuberculous cases.
2. That the patients were not fed well.
3. That they were not clothed well; that there was a deficiency of overcoats; that the patients had to use for drying their faces and hands towels which had been used already by other patients; and that, on the Commissioner's visits, the best of everything in the way of towels and brushes were brought out.
4. That due respect and care were not bestowed on the bodies of patients dying in the institution.
5. That cold baths were given as punishment by the attendants without the knowledge of a doctor.
6. That on numerous occasions one of the witnesses had seen patients struck on the abdomen and kidneys.
7. That patients were unnecessarily placed in seclusion rooms and made to wear strong canvas suits.

The findings of the Commissioners were. That "the allegations were in part justified." The report of this interview concludes:

"The allegations and our inquiry served a useful purpose, for they brought to light certain deficiencies and undesirable practices."

"In view of the seven allegations given in the Board's report as 'in part justified,' let us hope that the real facts of the position will be shortly elucidated in the only manner which can convey the full truth to the public—namely, by the appointment of a Royal Commission.—I am, etc.,

London, E., May 22nd.

S. E. WHITE, M.B.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

SIR.—We would draw the attention of the profession to a meeting to be held at 1, Wimpole Street, London, W.1, on Friday, June 9th, 1922, at 2.30 p.m., when it will be proposed that a "Medical Society for the Study of Venereal Diseases" be formed.

The number of those specially engaged on work in connexion with venereal diseases is ever increasing, and it is believed that the institution of a medical society for the study of venereal diseases would supply a widely felt need. Local divisions of the society will be formed and meetings will be held at which subjects of clinical, pathological, and administrative interest will be discussed. It is proposed to publish a journal if and when this is found to be practicable.

The society will doubtless attract medical practitioners engaged particularly in venereal diseases work, laboratory workers, and medical officers of health, but membership will be open to any medical practitioner who may be interested. While it is hoped that as many as possible of those interested will attend the meeting on the above date, it will be of assistance if those who contemplate becoming members of the society will communicate their intention now to the interim secretary.

The aim of the society—the uniting for the advancement of knowledge and the promotion of the common interests of those engaged in the study of venereal diseases—is one which we would cordially commend to the profession, and we would ask for it the wide measure of support which, in our opinion, it deserves.—We are, etc.,

Obituary.

W. D. SPANTON, F.R.C.S.,

Consulting Surgeon, North Staffordshire Infirmary.

We regret to announce the death, in his 82nd year, of Mr. William Dunnett Spanton, F.R.C.S., which took place on May 13th at Ripon Lodge, Hastings, where he had lived in retirement during the last few years. Mr. Spanton had had a busy and successful career as a surgeon in the Midlands, and he was an outstanding personality in the life of North Staffordshire for over half a century.

Mr. Spanton was born in September, 1840; he was the son of a schoolmaster, and was educated at Loughborough Grammar School and the Middlesex Hospital. In his autobiography, which, under the title of *The Story of My Life*, was published in 1920 (reviewed in our columns on July 16th, 1921, p. 78), Mr. Spanton gave some interesting reminiscences of his apprenticeship to a Loughborough surgeon in the late fifties, and of his life as a medical student in London in the early sixties. At the Middlesex Hospital, in his time, Alexander Shaw, Campbell de Morgan, Charles H. Moore, and Mitchell Henry were the surgeons, Alex. P. Stewart, S. J. Goodfellow, and H. Thompson the physicians, and Dr. Frere was physician-aecouchier; the latter, however, soon resigned, and Dr. Priestley (afterwards Sir William Priestley) took his place. Mr. Spanton lived for a time as assistant to a Dr. Brown of Clerkenwell, and there met Douglas Jerrold, G. A. Sala, and other men of note.

Mr. Spanton took the diploma of M.R.C.S. Eng. and the L.S.A. in 1862; he became F.R.C.S. Edin. in 1881, and F.R.C.S. Eng. in 1898. After serving as a house surgeon at Sheffield (where one of his experiences was the bursting of the Bradford reservoir) his long connexion with the Potteries began by his appointment in 1864 to be house-surgeon at the North Staffordshire Infirmary, Etruria. He was afterwards on the active honorary staff for thirty-four years; he resigned the post of surgeon and was appointed consulting surgeon in 1903. For many years he was the leading surgeon in North Staffordshire, where he was regarded as the doyen of his profession. Through his efforts many improvements were made in the buildings and in the organization of the North Staffordshire Infirmary, which brought it into a leading place among modern provincial hospitals.

He was a very old member and office-bearer of the British Medical Association, and for many years regularly attended its annual meetings. He was an energetic member of the Parliamentary Bills Committee of the Association, to which he was appointed in 1900, and was a member of Council from 1901 to 1908. For some years he was a member of the executive committee of the North Staffordshire Division; he was chairman of that Division in 1904 and president of the Staffordshire Branch in 1912. In 1903 he was vice-president of the Section of Obstetrics and Gynaecology at the annual meeting at Sheffield, and in 1911 he was vice-president of the Section of Surgery at Birmingham. As he showed in his autobiography, he had many pleasant memories of the annual meetings, and "often learned a good deal, met many friends, visited many delightful places under the pleasantest auspices: in short, always seemed to come back invigorated." Mr. Spanton enjoyed attending international medical congresses at home and abroad, and he made many holiday voyages to different parts of the world. He was the last president of the old British Gynaecological Society before it was amalgamated with the Royal Society of Medicine, and he contributed many articles, chiefly on gynaecological and surgical subjects, to this and other medical and scientific journals. Since 1892 he had been a justice of the peace for the county of Stafford, and he was president of the Staffordshire Nurses Institution, president of the North Staffordshire Field Club (which he founded), and consulting surgeon to Longton Hospital.

Mr. Spanton was an accomplished and distinguished surgeon, a man of many-sided culture, of impetuous disposition, but of a very kind and generous heart. He was married in 1867, but his wife and his three sons died some time ago; he is survived by his three daughters.

DUGALD CHARLES BREMNER, M.B., C.M.

DR. DUGALD CHARLES BREMNER, the surgeon of the *Egypt*, was the son of Dr. Bruce Allan Bremner of Edinburgh, and was born in 1869. He was educated at Craigmount School and Edinburgh University, graduating M.B., C.M. in 1892; he had been president of the Royal Medical Society, Edinburgh, and had held resident posts at Edinburgh Royal

Infirmery and the East Riding Asylum, Beverley. He was formerly in practice at Peebles, and was visiting physician to Peeblesshire Fever Hospital.

Dr. ARNOLD CHAPLIN, Medical Inspector to the P. and O. Company, writes: On behalf of the P. and O. Company I am requested to express their deep regret at the death of Dr. Bremner, the surgeon to the ss. *Egypt*, who lost his life in the disaster to that vessel on May 19th. Dr. Bremner joined the medical service of the company three years ago, after a distinguished career in the army during the war, where he held the rank of major. He soon proved himself to be exceptionally endowed with the qualities necessary for the successful performance of the duties of a medical officer on board ship. His promotion was rapid and in a very short time he was appointed to the *Egypt*, remaining there in medical charge until the ship was lost. His medical ability was considerable, and his high character as a man rendered him popular with all with whom he came into contact. He was one of the best medical officers the company has ever had, and the P. and O. Company desire to place on record their appreciation of his work while engaged in their service.

THERE has recently passed away in Lisburn, co. Antrim, Dr. GEORGE ST. GEORGE, a man with many outstanding characteristics and of great ability. For over fifty years he was surgeon to the County Antrim Infirmery, having served his apprenticeship there under the renowned surgeon Dr. Thompson, who was known to express very high commendation on the deftness and ability with which Dr. St. George performed his duties. His work at the infirmery during all these years was the chief interest and delight of his life. He achieved very remarkable surgical successes, and his powers of diagnosis were of a high order. His knowledge of prescribing and pharmacology was wide, and his quick resource in emergencies was often a means of saving life. His sense of duty was intense, and any cause to which he put his hand never failed to get his best. He held many other appointments, one of which was physician to the Thompson Memorial Home for Incurables, the inmates of which loved to see his cheery face and hear his laugh. He was recently mayor of the town of Lisburn, and was a member of its council nearly all his working life. He was much sought after in connexion with the social life of the town and neighbourhood, and was a faithful member of the local Branch of the British Medical Association and of the Ulster Medical Society, taking an active part in their management. Dr. St. George possessed deep religious principles, worshipping in the Protestant Cathedral, and was an ardent temperance advocate. In short, he was one of the old school of Christian gentlemen, an able physician and surgeon, and we leave him to the rest which he so nobly and faithfully earned.

THE death took place, on May 13th, of Dr. JOHN ROBERT JONES of Penrhyn Dendraeth, Merionethshire; he had recently undergone a serious operation. Dr. Jones received his medical education at Anderson College, Glasgow, and qualified with the diplomas of L.R.C.P., L.R.C.S. Edin., and L.R.F.P.S. Glas. in 1889. He was a justice of the peace for the county of Merionethshire, medical officer to the local infant welfare centre, and for thirty years had been medical officer to the Dendraeth district of the Festiniog Union. He was an old member of the British Medical Association. He is survived by his widow and two daughters.

WE regret to record the sudden death, on May 13th, of Dr. JOHN ALFRED LAYCOCK, of Sabden, near Blackburn, at the age of 61. Dr. Laycock received his medical education at Manchester, and qualified with the diploma of L.R.C.P.I. in 1885. He had been in practice at Sabden for some thirty-seven years, and had gained a high place in the esteem of the inhabitants by his genial personality and his generous patronage of all good causes in the district. He was a member of the parish council, a manager of the local council school, a great lover of music, and an antiquary of more than local reputation. He had long been a member of the British Medical Association.

WE regret to announce the death of Dr. BENJAMIN STRACHAN, which took place suddenly at his residence in Morningside, Edinburgh, on May 8th. Dr. Strachan was born in Fyvie, Aberdeenshire, in 1842, and in 1856 entered Marischal College, Aberdeen, where he graduated M.A. at the early age of 17. He then studied theology at St. Andrews and Glasgow, with

the intention of becoming a missionary, but he altered his plans and began the study of medicine in Glasgow, where in 1877 he graduated M.D., C.M. In the following year he was elected one of the late Dr. James Smith of Glasgow's successors in practice. Owing to the strain of heavy work he was obliged to retire from practice in 1898. His kindness, gentleness, and professional ability made him beloved and respected by all who came in contact with him. Dr. Strachan was a man of uncommon intellectual gifts and deep religious convictions. A profound Hebrew and Greek scholar, he remained a keen student to the end. He is survived by his widow, three sons, and three daughters.

In giving an account of the funeral of Sir HENRY DAVY last week it ought to have been said that among the very large number of medical men present were all the members of the staff of the Devon and Exeter Hospital.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Gilbert Blane Medals.

THE Gold-Medal founded by the late Sir Gilbert Blane, Bt., to be given biennially, is awarded by the Director-General of the Medical Department of the Navy and the Presidents of the Royal College of Physicians and the Royal College of Surgeons. This year has been awarded to Grimwade, O.B.E., M.B., behaving at the examination held in February last for promotion to the rank of Surgeon Commander.

Three Blane medals which remained unadjudged owing to the absence of promotion examinations during the war have been awarded to Surgeon Commander Reginald St. G. S. Bond, M.B., F.R.C.S., M.R.C.P., D.P.H., Surgeon Commander Robert W. B. Hall, Surgeon Commander Sheldon P. Dudley, O.B.E., M.D., D.P.H., for the distinguished professional zeal and ability displayed by these officers throughout their service career.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 19th the Public Orator read an address which it is proposed to present to the Earl of Balfour, Chancellor of the University, conveying the Senate's appreciation of his work as British representative at the Washington Conference, and their congratulations on his appointment as a Knight of the Order of the Garter and on his elevation to the peerage.

The honorary degree of D.Sc. was conferred on Baron Anatole von Engel, late Curator of the Museum of Archaeology and of Ethnology.

The following medical degrees were conferred:

M.D.—W. Thomas.
M.B., B.Ch.—E. S. Orme, N. S. Hewitt.
M.B.—A. O. Courtis.

UNIVERSITY OF LONDON.

THE Bursar's Scholarship of the value of 135 guineas, and two of the value of 100 guineas each, in the Faculty of Sciences at the University of London, will be awarded on the results of an examination on Tuesday, June 27th. Entry forms, from the Secretary of University College, Gower Street, W.C.1, must be sent in not later than June 6th.

ST. THOMAS'S HOSPITAL.

The following scholarships and prizes have been awarded for 1922: P. M. W. P. Hudson; Grainger Testimonial; Hadden Prize, C. V. Patrick and C. P. R.; Medal, J. F. Hackwood; Toller Prize, J. Hadden Medal, C. V. Patrick.

UNIVERSITY OF MANCHESTER.

THE University Court on May 19th conferred the D.Sc. degree upon Professor H. R. Dean, who announced the approaching from the chair of Physiology of Chemistry.

In October next the fiftieth anniversary of the amalgamation of Owens' College with the Manchester School of Medicine will be celebrated.

UNIVERSITY OF LIVERPOOL.

At a congregation of the University of Liverpool held on May 19th the degree of D.Sc. (*honoris causa*) was conferred upon Sir Charles Sherrington, G.B.E., M.D., Waynflete Professor of Physiology in the University of Oxford and President of the Royal Society.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.
At the meeting of the College held on May 19th Lieutenant-Colonel Sir Joseph Fayer, Bt., on behalf of the officers of the 2nd Scottish General Hospital, presented to the College a silver bowl as a memento and a permanent record of the services rendered by its Fellows during the great war.

The following having passed the requisite examinations were admitted Fellows:

H. N. Bellune, R. B. Boston, F. D. D. Dickson, May E. Glancey, L. W. Innes, D. A. Laird, S. F. Lee, P. A. Miller, K. P. R. Pillai, S. H. Puch, T. H. Richmond, R. Thangamma, L. Watson-Williams, L. A. Wilson, Captain O. Wilson, I.M.S., J. M. Wishart.

The Bathgate Memorial Prize, consisting of bronze medal and microscope, 1as, after a competitive examination in Materia Medica, been awarded to Mrs. Grace Laubscher, and the Ivison Macadam Memorial Prize in Chemistry, consisting of bronze medal and set of books, has been awarded to Mr. D. B. Cruickshank.

Medical News.

SIR CLIFFORD ALLBUTT, Regius Professor of Physic, Cambridge, has been elected a Foreign Honorary Member of the American Academy of the Arts and Sciences (Boston, Mass.).

DR. GEORGE REID, O.B.E., who retired recently from the post of medical officer of health for Staffordshire (and who has been appointed consulting medical officer of health for that county), was the recipient on May 21st of a handsome presentation from the district medical officers of health in Staffordshire. Dr. Reid, who is a former President of the Staffordshire Branch of the British Medical Association and of the Society of Medical Officers of Health, was not only the first medical officer of health of Staffordshire, but the first county medical officer of health to be appointed in the kingdom. He is the author of the well-known textbook *Practical Sanitation*, now in its twentieth edition. During the war he served as a divisional sanitary officer, with the rank of Major R.A.M.C.(T.).

THE 195th dinner of the Edinburgh University Club of London was held at the Connaught Rooms on May 17th, with Lord Dunsedin of Stenton in the chair, when among the members and guests present were the Spanish Ambassador, the Lord Chancellor, the Marquis of Dufferin, Lord Justice Atkin, Sir G. Lenthal Cheate, Sir Henry Craik, Sir James Dundas Grant, Sir John Goodwin, Sir Robert Hill, Sir W. G. Macpherson, Dr. Nathan Raw, M.P., Sir Arthur Sloggett, Sir James Purves Stewart, and Sir John Thomson Walker. Lord Dunsedin, in proposing the toast of "Alma Mater and the Edinburgh University Club of London," spoke of his own student days at Edinburgh when he was a member of the Speculative Society with Robert Louis Stevenson and Lord Guthrie. The toast of "The Guests" was proposed in an amusing speech by Dr. Walter Jagger. In response H.E. Señor Don Merry del Val made an eloquent plea for the study of Spanish literature at the Scottish Universities, where it was neglected: their countries had many resemblances, for on the hills of both blue-bonneted men played bagpipes, while their universities were alike in being democratic institutions. Lord Birkenhead and Dean Inge also responded. The health of the Chairman was proposed by Mr. Alexander Macmorran, K.C. Graduates of Edinburgh University who wish to join the club are invited to write to the honorary secretary, Dr. R. S. Frew, 73, Wimpole Street, W.1.

THE fifth lecture in the series of post-graduate lectures arranged by the Fellowship of Medicine will be given on Tuesday, May 30th, at 5 p.m., in the West Lecture Hall of the Royal Society of Medicine, 1, Wimpole Street, W., by Sir Arbuthnot Lane, on the subject of stasis. The lectures are open to members of the medical profession.

A CIRCULAR has been issued by the Minister of Health stating that he has decided to recognize as official certificates for the purpose of the Public Health (Foreign Meat) Regulations certain labels and marks (which are illustrated and described in the circular) issued by the governments of the United States of America and the Argentine Republic.

A PRESENTATION was made recently at Sheerness to Dr. George Aldridge, who has retired temporarily from practice. Dr. Aldridge was in practice at Sheerness since 1935, and was formerly part-time medical officer of health for the district: he held other public medical appointments and was the founder of the St. John Ambulance Brigade in Sheerness.

THE annual dinner of the Federation of Medical and Allied Services will be held at the Café Royal, Regent Street, London, W.1, on Wednesday, June 7th, at 7.15 p.m. Sir Berkeley Moynihan, the President, will take the chair, and Sir Alfred Mond, Minister of Health, and his predecessor, Dr. Addison, will be expected to be present. Further particulars can be obtained from the Medical Director, 12, Stratford Place, London, W.1.

ON April 13th the retail business which the Society of Apothecaries of London has hitherto carried on at Apothecaries' Hall, Water Lane, E.C., was closed, and the society has handed over to the firm of Cooper, Son, and Co. the prescription books, formulae, and special preparations.

THE House and Library of the Royal Society of Medicine will be closed from Saturday, June 3rd, to Monday, June 5th, both days inclusive.

THE annual dinner of the Harveian Society of London will be held at the Café Royal on Thursday, June 15th, at 7.30 p.m.

THE annual general meeting of the Lebanon Hospital for Mental Diseases will be held at the rooms of the Royal Society of Medicine on Thursday, June 1st, at 4 p.m.

THE Harrogate Corporation has issued a handbook giving information for visitors in regard to the mineral waters and other attractions of the place. Copies may be obtained, free of charge, from the Publicity Manager, Royal Baths and Wells, Harrogate.

MR. W. HARRISON MARTINDALE, Pb.D., has prefixed to the new price list of the firm of W. Martindale a note in which he appeals to the profession to support British chemical and pharmaceutical industries. He states that the Safeguarding of Industries Act, 1921, though a step in the right direction, only attacks the merest fringe of the subject.

A MEETING of the International Council of Nurses opened in Copenhagen on May 22nd. The delegates, who were the guests of the Danish Council of Nurses, were welcomed by the President, Mrs. Keny Tscherning. The Council was founded in 1899 by federation of the National Councils of Nurses of Great Britain and Ireland, the United States of America, and Germany, to which the National Associations of Canada, New Zealand, India, Holland, Denmark, and Finland have since affiliated.

A GROUP of American surgeons is to make a clinical tour to Europe this summer under the direction of Dr. James L. Smith of Chicago. They have arranged to spend three days in Liverpool (June 19th to 21st), three in Edinburgh, two in Leeds, and four in London. The party—the members of which will be accompanied by their families—will then proceed to the Hague, Paris, Switzerland, Italy, Tyrol, Bavaria, Dresden, and Berlin; they expect to reach New York on their return journey on August 26th.

THE Council of the Medical Officers of Schools Association has decided to suspend the issue of the journal, *School Hygiene*, until such time as the cost of printing falls. In order that members may be provided with the papers read before the association's meetings and be kept in touch with the subject of school hygiene, a yearbook will be issued at the end of 1922.

UNDER the auspices of the National Association for the Prevention of Infant Mortality and National Baby Week Councils a series of conferences on infant welfare will be held at Carnegie House, 117, Piccadilly, London, from Monday, July 3rd, to Wednesday, July 5th, culminating in a public meeting in the council chamber of the Caxton House, Westminster. Discussions will take place on "The position of the district nurse and midwife in relation to public health services in rural areas," "Rickets," "How far should treatment be undertaken at an infant welfare centre?" and other subjects. Arrangements will be made for conducted tours by motor car to a number of typical maternity and child welfare institutions of various kinds in London. Particulars and tickets may be had on application to the honorary secretary, Miss J. Halford, Carnegie House, 117, Piccadilly, W.1.

MESSRS. BAIRD AND TATLOCK have sent us a copy of the 1922 edition of their *Standard Catalogue* (Vol. II) of *Physiological, Histological, and Biochemical Apparatus and Instruments*; in it are included autoclaves, sterilizers, surgical instruments, polygraphs, sphygmomanometers, ophthalmoscopes, and other instruments, and models of the eye, brain, etc., for teaching purposes. The catalogue has been prepared, we are informed, with the help of a number of physiologists; it appears to be very comprehensive and it is well illustrated.

THE *Internationales Centralblatt für Laryngologie, Rhinologie und verwandte Wissenschaften*, founded by the late Sir Felix Semon in 1884, has ceased publication with the March number, and will reappear under the title of *Centralblatt für Hals-, Nasen- und Ohren-Heilkunde*. Dr. Georg Finner, who succeeded Sir Felix Semon in 1908, will continue to be editor of the new journal.

A BRONZE memorial tablet has been erected in an operating theatre dedicated to Dr. J. Mariou Sims in the Woman's Hospital, New York. The inscription on the tablet reads as follows: "Sims Operating Theatre, dedicated to the memory of James Mariou Sims, M.D., LL.D., 1813-1883, the Founder of the Woman's Hospital and of Modern Gynecology."

THE firm of John Bell and Croyden, Ltd., incorporating Arnold and Sons, have acquired the lease of No. 52, Wigmore Street, which adjoins the existing premises at 50 and 50A, Wigmore Street. It will be used as showrooms for hospital furniture, surgical instruments, orthopaedic appliances, and invalid furniture.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4381, Central).

QUERIES AND ANSWERS.

"T. I. M.," who suffers from bronchitis and emphysema, has been advised to remove from Yorkshire to some place where the climate will not aggravate his condition. He asks for suggestions for a suitable place either at home or abroad.

TREATMENT OF CRAMP.

"A.E." suggests to "M.D. Edin." (BRITISH MEDICAL JOURNAL, p. 744, May 6th, 1922) that during the cramps every effort should be made to use the opposing muscles—for example, if the cramp be in the calf, try perseveringly to straighten the knee and dorsiflex the foot, and so on. Surely, he says, this is physiological and sound advice. "A.E." further remarks: Acting on this idea I have relieved abdominal spasms by trying to induce instant retching or vomiting by finger tip in the fauces. Unfortunately, when the pain has become intense, the reflex action of vomiting will not be induced. In that case drinking any harmless fluid in large quantity should be followed by a further effort at retching or vomiting. Aspirin often gives relief quickly. Probably "M.D." will find fomentations of sodium salicylate very useful for his joints.

INCOME TAX.

"F. T." is a medical officer in one of the Crown Colonies. He is returning to settle in practice in England, and will then be entitled to a gratuity of £1,000 and, further, four and a half months' pay, amounting to £360 odd, payable through the Crown Agents.

* * From the date of his return to the United Kingdom "F. T." will become a British resident for income-tax purposes, and we are of opinion that he would be liable to tax on the £360 as accruing after he takes up that status, whether it is paid into his own bank account or dealt with otherwise. As regards the gratuity, we should regard that as earned during his colonial service, and therefore as a receipt of capital, not income, so far as this country is concerned.

"H. W. G." inquires as to the replacement allowance for a car.

* * The only amount properly allowable is the amount spent on maintaining the professional equipment; where an improved type of car is purchased the expenditure covers something more than mere maintenance. We advise "H. W. G." to accept the figure of £350 for the purpose of the claim.

"CROSSENS" bought a new 15.9-h.p. car in 1914 for £290 and sold it for £250 in 1921, when he bought a new 20-h.p. car of the same make for £683; a 16-h.p. car of the same make would then have cost £663.

* * On the facts as stated the replacement cost allowable is £663 less £250—that is, £413.

"P."—The circumstances are briefly as follows: P and Q were in partnership on an equal-share basis, though Q's fees accounted for two-thirds of the cash receipts. Q died, and his share of the practice has been sold to R, and P and R now carry on their work as separate practitioners and are assessable as such. Our correspondent asks how the assessments should be based.

* * P and R are assessable on the basis of the average profits in the past three years earned in the practices as now constituted—that is, on the facts stated R's assessment would be twice that of P. The basis of the payment made by R is material as evidence of the share taken over, but is not conclusive; if he paid on a "half" basis for "two-thirds" of the practice he is

not thereby entitled to say that necessarily he took over only one-half. We may add that if for any specific cause the profits of either P or Q fall short of the sum assessed an adjustment can be claimed at the end of the year of assessment.

LETTERS, NOTES, ETC.

THE "SALIVARY TEST" AS A ROUTINE.

DR. A. A. WARDEN (Paris) writes: I remember—now, alas! more than twenty-five years ago—that my chief, Sir Hector Cameron, once asked me, in one of his inimitable asides, if I knew the real translation of the phrase, *γινώσκει σκατόν* (know thyself), and on my answer in the negative, said, "Test your urine." The little jest has often come to my mind, but recently I have been wondering if a still more significant rendering might not be "Test your saliva." I am well aware that much research, though of little pathological value, has been spent on the chemical and bacteriological examination of the saliva, and I shall not weary your readers by references to the increasing amount of literature on the importance of pyorrhea, pus pockets, and infection generally in the mouth as a causal factor in general systemic diseases—arthritis, gastro-intestinal affections, nephritis, etc. My object in this note is to ask why examination of the saliva is not as routine a procedure as that of any other body fluid. It is a simple matter to rinse the mouth thoroughly two hours or so after the last meal and then collect the saliva for the next thirty minutes or until the test tube contains from 10 to 20 c.cm. Mastication means traumatism, and the maximum amount of pus production appears about two hours later. Even a casual inspection will reveal, with surprising frequency and in mouths that seem models of the dentist's triumph in the shape of shining golden crowns and bridges and inlays, the presence of both blood and pus. For a generation the dentist has prided himself on his conservative work and his skill in salvaging dead teeth—now more and more regarded as dangerous sources of infection. A child's mouth free from caries, or an adult's with teeth and gums in good condition, should show, in 20 c.cm. of saliva, a precipitate in twenty-four hours of only a few centigrams of debris. In many mouths that appear clean such a test may well show several grams of yellowish white precipitate of red blood cells, leucocytes, food debris, mucus, and microbes. It is no easy matter to estimate the amount of pus present or to measure its pathological significance, but the naked-eye test alone—for the use of which I am indebted to my friend, Dr. Rodolfo Roblés—is of great value.

DRUG ADDICTION.

DR. W. V. FURLONG (Dublin), in the course of a letter on this subject, writes: Your article on opium and cocaine consumption in the different countries of the world is very important, though of course we cannot do without these drugs when necessary, but the enormous amount used secretly shows that the number of drug takers in the world must be greatly on the increase. It is often a wonder to me that so many people who preach against the inordinate use of opium and cocaine should not include also in their condemnation tobacco and alcohol, which are equally pernicious drugs. There are a far greater number of people who exceed the safe limit in tobacco and alcohol than in any other drug known, and the effect of overdoses of either are much worse than opium or cocaine. Everyone in the medical world knows the effects of chronic nicotine poisoning on the arteries, heart, eyes, etc.; and its pernicious effects upon every organ in the body, and still no effort has been made to stop this growing evil, although its victims must number fully 1000 for every one from opium or cocaine. Every doctor has daily to treat cases of atheroma, heart disease, amblyopia, etc., which frequently can be traced to the excessive use of tobacco. The effects of the excessive use of alcohol on the brain, liver, heart, and lungs are too well known by all doctors to require recapitulating here.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 28, 29, 32, 33, and 34 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 30 and 31. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 199.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so delivered, addressed to the Manager, 429, Strand, London, or if not paid for at the time, should be accompanied by a reference. NOTE.—It is against the rules of the Post Office to receive postal remittance letters addressed either in initials or numbers.

MEDICINE.

599. Phenolphthalein Eruptions.

WISL and ARAMOWITZ (*Arch. of Derm. and Syph.*, March, 1922) draw attention to the occurrence of a peculiar eruption of the skin in susceptible persons after the ingestion of phenolphthalein, so commonly used as a laxative, not only in medical practice but as a constituent of many proprietary medicines. This eruption consists of a few widely scattered and numerous irregularly grouped polychromatic macular plaques, varying in diameter from that of a pin's head to several inches, and in colour from pink to bright red, dusky violaceous, and deep purple; it is relapsing in course, chronic in nature, and usually results in a protracted pigmentation of the affected areas of the skin. Slight scaling may accompany the evolution of the lesions; a peculiar mottling is sometimes seen in the central zone of the macules; vesiculation, erosion, and superficial ulceration may occur, especially on the mucous membrane of the mouth and on the genitals; a burning sensation sometimes precedes and accompanies the appearance of the patches; moderate to severe itching may be a symptom during their evolution. The eruption is a persistent multiform erythema, which, instead of vanishing without leaving a trace, persists more or less indefinitely and terminates in a yellowish-brown deposit of pigment in the affected sites. After the subsidence of the active lesions relapses are apt to take place following the ingestion of phenolphthalein. Mild constitutional symptoms, such as headache, malaise, slight rise of temperature and pulse rate, may accompany the relapses. As far as the authors are aware, only one other toxic agent is capable of causing an identical eruption, and that is antipyrin, though eruptions having many points of resemblance to those caused by phenolphthalein and antipyrin are sometimes found after the use of arsenphenamin and neo-arsphenamin. A number of cases are given, together with illustrations, general histories, and dermatological and histological descriptions. Brunettes seem to be more susceptible, and the normally hyperpigmented areas of the skin are the favourite sites of the eruption. The sections of lesions show an excess of melanoblasts which are said to be related to the chromaffin cells of the suprarenals, and are increased in suprarenal insufficiency. As the use of adrenaline has been found beneficial to persons who react to arsenphenamin, this points to the possibility that the patients susceptible to these drugs and exhibiting these peculiar skin rashes have hypoadrenalism. These patients feel weak and depressed after taking phenolphthalein, and they have a slight rise of temperature and pulse, which points to a general metabolic disturbance and a possible splitting up of the drug in the body, and not in the skin itself. The authors think the hypertrophy of the melanoblastic elements in the skin is caused by hypoadrenalism, but the administration of epinephrin to these sensitive patients does not seem to prevent or retard the eruptions.

500. The Treatment of Malaria.

MAYER (*Klinische Wochenschrift*, March 11th, 1922) gives a summary of his experience and views of the treatment of malaria. Quinine should be given at once, and if, after five days' treatment, the fever does not cease, usually the diagnosis is wrong. The average daily dose should be 1 gram of quinine hydrochloride, best given in five doses of 0.2 gram, or four doses of 0.25 gram. Intramuscular injection is usually unnecessary, and is not superior to internal administration. In very severe cases, especially in tropical malaria with comatose symptoms, at first one or two intravenous injections are indicated. They often save life. The dose should not exceed 0.5 gram, and often 0.3 gram is sufficient. Quinine urethan (supplied in ampoules) is the best form for injection. It should be diluted in the syringe with 10 c.c.m. of sodium chloride solution. In the acute attacks of malaria, quinine (by mouth) should be continued daily until the fever ceases, and for three or four days afterwards. In very severe cases a daily dose of 2 grams (instead of 1 gram) may be given for two or three days. More than 3 grams daily is useless and injurious. Mayer recommends the quinine treatment for six weeks with intermissions—discontinuing the drug for two to five days and giving it in intervening periods of three to two days. Quinine hydrochloride is usually given; the sulphate is of similar value; the tasteless tannate should be given in larger doses. Quinine should not be taken on a full stomach. Tablets or capsules should be periodically tested, by placing in water, to see if they are friable. Methylene-blue has a

relatively good effect in quartan ague. In the chronic malarial sequelae quinine should be given first, and then arsenic. In blackwater fever quinine should be discontinued at once.

501. Exophthalmic Goitre and Digitalis.

BRAM (*Med. Record*, February 18th, 1922) considers that digitalis may be of value in the passive stage of exophthalmic goitre when it is well tolerated and the patient readily responds to its action, but that in the active stage it is harmful and may aggravate the syndrome. Very occasionally and cautiously used in auricular fibrillation its intermittent administration may help to regulate cardiac action, but will not lessen frequency. In the passive stage it is best administered for three or four weeks and then withdrawn, to be administered again for a short course should the heart rate show signs of rising above normal, after which it will be possible in most instances to withdraw it permanently without fear of a fresh rise in frequency. Dosage should be small and results awaited rather than attempt to obtain a physiological effect quickly, and a standardized preparation should be used so that its effect can be carefully watched.

502. Atypical Typhoid Fever.

ZWEIG (*Wien. klin. Woch.*, January 6th, 1922) remarks that atypical cases of typhoid fever can be divided into three groups: (1) Cases in which typhoid simulates another infectious disease, such as influenza, malaria, or dysentery. (2) Cases in which the typhoid bacillus settles in some part of the system with little or no involvement of the intestinal tract. (3) Cases in which there are few or no lesions in the organs, and the diagnosis is established only by blood culture. Zweig reports a fatal case in a woman in whom a pure culture of typhoid bacilli obtained from the blood and organs after death and a positive Widal reaction were the only evidences of typhoid infection. The temperature, which was characterized by marked remissions, suggested septicæmia. The autopsy showed recent hæmorrhagic lobular pneumonia of both lower lobes, purulent embolic nephritis, and hyperæmia and swelling of the mesenteric glands. Although the disease at the time of death had lasted a fortnight and had set in with intestinal symptoms, no specific changes were found in the small or large intestine. A pure culture of *B. typhosus* was obtained from the bile and typhoid bacilli associated with *B. coli* were isolated from the kidneys.

503. Injury to the Pituitary Body by Epidemic Encephalitis.

BARKMAN (*Acta Medica Scandinavica*, vol. 56, fasc. ii, 1922) has observed two cases in which epidemic encephalitis was followed by an enormous increase of weight, due to accumulations of fat in the buttocks, breasts, and other parts. In one case, that of a prison warder aged 35, the increase of weight was about 35 kilos; the expression of the face was childish and the contour of the body feminine. Two years after the encephalitis sexual activity was much reduced and the skin was soft, dry, and thin. The author details numerous other changes indicative of impaired function of the pituitary body, and he refers to three recent publications, showing that this sequel to epidemic encephalitis is not suggests that if this sequel were to be for in persons who had undergone several cases would be found in which it had permanently injured the pituitary body.

504. Results of Sanatorium Treatment of Tuberculosis.

FOWLER (*Tubercle*, April, 1922) has investigated the fate of 1,364 patients two to six years after discharge from a sanatorium. Patients staying less than a month and those in whom the diagnosis of tuberculosis was not definite were excluded from this investigation. The total mortality among these patients, who belonged almost exclusively to the industrial classes, was 34.2 per cent.; but as many as 24.6 per cent. of all the patients were in the third stage of the disease on admission. The percentage of cases still at work was 48.6, and, if the third stage cases be excluded, 59.3 per cent. were still at work. Of the first stage cases only 8.5 per cent. had died. The author calculates that a first stage patient is four times as likely as a second stage patient to live for more than two years, and nearly nine times as likely as a third stage patient. Three-fourths of his first stage patients and one-sixth of his third stage patients were still able to work. Classifying his patients according to the positive or negative condition of their sputum, the author found 645 in the former

class and 676 in the latter. Patients coming under treatment after tubercle bacilli had appeared in the sputum had a death rate more than five times greater than that of patients treated before tubercle bacilli had been found. The proportion of patients still able to work was more than twice as great among the sputum-negative as among the sputum-positive cases. The highest rate of mortality occurred in the first two years after discharge, and the author calculates that if a patient survives for five years after discharge his chances of continuing to live are very considerable. The author admits that it is impossible to assess the value of sanatorium treatment till a similar analysis has been made of a large series of comparable cases not undergoing sanatorium treatment. Even then the educational value of the sanatorium could not be gauged.

505. Treatment of Arterial Hypertension.

HOUGHTON (*Med. Record*, March 18th, 1922) urges the treatment of arterial hypertension with a low sodium chloride dietary, since the immediate or determining cause of the condition is a larger intake of sodium chloride than the kidneys can excrete, frequently complicated by excess of water and the possible retention of uric acid. Previous attacks of acute infectious disease, notably scarlet fever, and the absorption of toxins from local septic foci, are factors determining the kidney limitations in dealing with excretion. Patients with pressures over 200 mm. should be limited to a dietary of low purin content, containing not more than 500 c.c.m. of water, and not more than 4 grams of sodium chloride, a preliminary blood examination being made to determine its sodium chloride, uric acid, and sugar content. When, on such a diet, the pressure has gradually come down to 150 mm., the sodium chloride intake is brought down to 2 grams daily. If, after a four-day period, a twenty-four hour specimen of the urine shows an output of more than 2 grams of sodium chloride, the diet is not sufficiently free from it and the pressure will not have reached normal; the dietary must therefore be continued. Cardiac complications benefit much by the reduction in blood pressure from a low salt diet, and its indication in the treatment of diabetes, toxic eye conditions, toxæmias of pregnancy, and in the post-operative care of surgical patients, is borne out by the fact that the cells of the thyroid, pancreas, eye, and endothelium of the arterial walls suffer, as well as the renal epithelium, from the processes of past infections and from septic foci.

SURGERY.

506. Carcinoma of the Prostate.

BARRINGER (*Surg. Gyn. and Obstet.*, February, 1922) considers the diagnosis and treatment of this condition, especially in relation to the value of radium applications in treatment. In most of the cases examined the growth had spread beyond the prostate; the commonest extension was towards the seminal vesicles, and not uncommonly to the lateral pelvic walls; the rectal wall was only rarely involved, and only one case of metastasis in the anterior urethra was seen. He has no records of the frequency of distant metastases. The most frequent early symptom was disturbance of micturition, whilst hæmaturia was sometimes observed, likewise pain. Nothing in the symptoms can distinguish carcinoma from simple enlargement of the prostate, though hæmaturia is more frequent in the latter condition. As so many cases are impossible to cure when seen, he concludes that only by a regular examination of the prostate in all beyond the age of 50 will it be possible to get these cases early. Radium is applied to the prostate by inserting steel needles through the perineum into the lateral lobes, under local anaesthesia. When the prostatic urethra is invaded, tubes of screened radium are inserted through a urethroscope into the urethra. In the author's experience the results of radium treatment for carcinoma of the prostate are superior to operative removal, both in causing regression of the disease and coping with urinary retention. The application of radium tubes to the neck of the bladder, or the needle method in the prostate, may be used to reduce the residual urine with success in some cases. In only 2 per cent. of cases of carcinoma of the prostate examined is the growth apparently confined to the prostate.

507. Oesophageal Diverticulum.

SEUCERT and FERRY (*Bull. et Mém. Soc. Chir. de Paris*, February 28th, 1922) report a new and interesting example of this condition. By means of radiography and oesophagoscopy the pouch was recognized and localized on the right side, which is unusual. As a result of the precision diagnosis the whole operation was performed under local anaesthesia. The patient, a male aged 34 years, had suffered

from dysphagia for several years. In 1918 he noticed for the first time a sensation of tickling in his throat; a few months later he had difficulty in swallowing. He lost 18 lb. in weight during a period of three months. Palpation of the neck revealed nothing abnormal. If, during the examination, he swallowed a few mouthfuls of water, a swelling appeared on the right side of the neck, deeply situated and difficult to define in outline; at the same time the patient noticed a sensation of gurgling in the neck. X-ray examination gave definite information, and examination on the screen showed the bismuth meal collect above the clavicle, filling a kind of pouch the size of a small egg. Examination with the oesophagoscope showed a diverticulum opening behind and to the right, and lying on the right side of the neck. Operation was carried out under local anaesthesia, the incision being made on the right side of the neck; the pouch was dissected out, the pedicle freed, and the diverticulum removed. Two layers of sutures were used to close the opening; the wound was then sutured, with drainage. The patient made a satisfactory recovery. Examination of the pouch showed that at its origin the walls were thick, becoming thinner towards the distal end. At its origin the wall contained a thick layer of muscle, whilst at its extremity the wall was reduced to a mucous and submucous layer. Diverticula are usually found on the left side of the oesophagus; in this case it lay on the right side, which is exceptional.

508. Haematuria from Rupture of a Vesical Varix.

MARION (*Journ. d'Urologie*, December, 1921) remarks how often the physician in a case of hæmaturia, being ignorant of the origin of the bleeding, tells his patient that it is due to rupture of a varicose vein in the bladder. Urologists know, on the other hand, how rare this condition really is. The author records a case of this nature, the first he has seen, the patient being a boy of 17 years. Hæmaturia had been persistent for ten days without becoming less. There was much blood in the urine and profuse blood clots were passed, but they did not interfere with micturition; the blood was chiefly terminal. It was the only symptom present, no pain being noticed, and was spontaneous in onset. The patient at the age of 4 years had an attack of hæmaturia, but of shorter duration. An examination of the boy showed well-marked varicose veins on the right leg, the presence of a varicocele, and dilated veins in the lower part of the abdomen. These lesions were congenital. This condition suggested that the hæmaturia was the result of a ruptured vein in the bladder; this was confirmed by cystoscopic examination. A network of dilated venules was seen on the right wall of the bladder, and at one point a stream of blood was seen coming out from a small bluish ulcer; this showed the origin of the hæmaturia. Marion then carried out cauterization of the bleeding point, and at the end of a few seconds the bleeding was arrested. There has been no recurrence of the bleeding.

509. The Pathogenesis of Gastric Ulcer.

BRISOTTO (*Rif. Med.*, February 6th, 1922) criticizes the various theories put forward to explain the formation of gastric ulcer. Hyperchlorhydria, he holds, is not the primary factor, nor sufficient by itself to explain the pathogenesis of the ulcer. Nor will the vascular theory suffice, all the more since the gastro-duodenal arteries are rich in anastomoses. The inflammatory hypothesis will not explain why the ulcer is often single. Traumatism is not a satisfactory explanation. The neurogenic theory is rather more satisfactory, as trophic lesions follow affections of the vagus; and if to this is added the influence of the endocrine glands, especially the suprarenals, in trophic changes, through the vagus and sympathetic, a cause which unifies the various adventitious causes may perhaps be found.

510. Operative Treatment of Embolism of the Limbs.

SINCE 1912 KEY (*Acta Chirurgica Scandinavica*, January 17th, 1922) has performed embolectomy in 8 cases, and with increasing experience he has found that the interval between embolism and the operation may be considerable without the operation being unsuccessful. In his first case this interval was one of seven hours; in his last case, operated on in 1921, it was as long as twenty-two and a half hours. He finds, however, that after the tenth hour the prospects of the operation being successful steadily grow less, and he has come to this conclusion from a study of the literature of 45 cases in which 48 operations for the removal of an embolus were performed. The ultimate results are greatly spoilt by recurrences of the embolism and other sequelæ to the primary disease of the heart which is responsible for most of these cases of embolism. But in several cases embolectomy has given the patient a new lease of life measured in years spent in comparative health. In no fewer than 20 cases mitral disease was diagnosed, and the common

femoral artery was the site of the embolism in 22 cases. Of the 23 operations performed within the first twenty-four hours 13 were successful, and of the 12 cases operated on within the first ten hours as many as 9 were successful. The author refers to Nicolaysen's case, in which the interval between embolism and operation was twenty-eight days, but the "record" for successful operation seems to be held by the author with an interval of twenty-two and a half hours between embolism and operation.

511. Hydatid Disease of the Spleen.

LUBBERS and NOORDENBOS (*Nederl. Tijdschr. v. Geneesk.*, February 4th, 1922), of Amsterdam, who record a fatal case of hydatid disease of the spleen in a man aged 26, state that only two previous cases of splenic cysts have been recorded in Dutch literature, one of which was a hydatid cyst, while the nature of the other was not established. According to the statistics of various observers the spleen is involved in 3.35 per cent. of all cases of hydatid disease. The parasite may develop centrally, as in the writers' case, or peripherally, the splenic tissue forming a thin covering to the cyst. According to Trinkler, central development is the commoner. In hydatid disease of the spleen adhesion of the cyst with the surrounding tissue occurs early, especially when the cyst is large. There are no characteristic features to distinguish parasitic from non-parasitic cysts of the spleen. The symptoms are chiefly caused by pain due to the increasing size and pressure of the cyst. Hydatid thrill is only seldom found in hydatid disease of the spleen, and was not present in the writers' case. The prognosis depends on whether the spleen is the only localization of the *celibococcus*, or whether the parasite has invaded other organs as well. Generalized hydatid disease, according to Kahlkopf, is an extremely dangerous condition. The prognosis, however, of hydatid disease confined to the spleen is not nearly so favourable as that of non-parasitic cysts of this organ. In rare instances spontaneous cure may occur through rupture of the cysts into the alimentary canal or through death and calcification of the parasites. The best method of treatment consists in marsupialization or splenectomy.

512. Perforation of Malignant Ulcer of the Pylorus.

LECÈNE (*Bull. et Mém. Soc. Chir. de Paris*, February 21st, 1922) reports the case of a man, aged 36, who was operated upon for a perforated gastric ulcer three hours after the perforation had occurred. The abdomen was found to contain several litres of free fluid, and a perforation was found on the anterior surface of the pylorus. This was closed with difficulty owing to the hardness of surrounding tissues. A posterior gastro-enterostomy was then carried out; a drain was inserted and the abdomen closed. The patient died forty-eight hours later. An autopsy proved that the ulcer was malignant. Lécène points out that perforation of a gastric carcinoma into the peritoneal cavity is on the whole a rare complication; in 710 cases of carcinoma of the stomach only 8 cases of perforation were found. The difficulties met with in this operation were considerable; the ulcer was surrounded by masses of glands and fixed to the pancreas and liver. As the closure of the perforation was so difficult a gastro-enterostomy was considered necessary; this only lengthened the operation by a short time, and he does not think it hastened the fatal ending, which was rather due to the excessive amount of fluid from the stomach found in the peritoneal cavity. He considers that the post-operative prognosis in cases of perforated gastric and duodenal ulcer depends to a great extent on the character of the fluid found in the peritoneal cavity. In this case a bacteriological examination was not made.

513. Post-Scarlatinal Inflammation of the Orbit.

SALOMONSEN (*Hospitalstidende*, January 25th, 1922) notes that opinions are divided as to the best course to pursue when scarlatinal ethmoiditis leads to inflammation of the orbit, with oedema of the eyelids, conjunctivitis, lacrimation, protrusion of the eyeball and limitation of its movements. The clinical picture is remarkably uniform, and to anyone unfamiliar with it the symptoms are most alarming. But the author has come to the conclusion that the prognosis is good, and that it is seldom necessary to do more than apply hot or cold compresses and instil cocaine and adrenaline into the nose. In the course of three years he has seen 20 such cases, only 3 of which were bilateral. In only 2 cases was operative interference required, and in no case was any injury to the interior of the eye observed. There were not even errors of refraction due to the pressure on the eyeball. Every case terminated in recovery, and re-examination of 10 cases after discharge from hospital showed a perfectly normal state of affairs. It is not, therefore, likely that conservative treatment entails any serious risk of chronic ethmoiditis. The inflammation of the orbit is probably due to direct extension of disease in the ethmoid cells through the thin layer of

bone (often imperfect in childhood) separating the ethmoid cells from the orbit, and when suppuration occurs in the orbit escape of pus through the nose may be interpreted as the result of inflammation of the ethmoid cells alone. It is therefore difficult, to estimate the frequency with which inflammation of the orbit leads to suppuration, but in the overwhelming majority of cases the disease begins and ends with an inflammatory oedema which appears first at the inner canthus, spreading thence to the whole of the eyelids. The disease often lasts only three to four days, and in only two of the author's cases did it persist for twenty days.

OBSTETRICS AND GYNAECOLOGY.

514. Pre-Caesarean Hysterectomy.

ACCORDING to SOLIERI (*Il Morgagni*, February 15th, 1922) Roger, in 1903, was the first to suggest the possibility of removal of the intact gravid uterus as a preliminary to extraction of the foetus, and having tried this operation in a goat was successful in obtaining by it two living kids. Solieri reports the case of a primipara, aged 37, who had well-marked pelvic contraction associated with congenital dislocation of the hip: labour occurred at normal term and thirty-eight hours after rupture of the membranes the patient, who had been subjected to repeated examinations, was found to be febrile and to exhibit redness and swelling of the vulvo-vaginal mucosa from which a muco-purulent secretion exuded. In view of the danger of performing an ordinary Caesarean operation in the infected state of the patient the writer had recourse to pre-Caesarean hysterectomy. After clamping the round and utero-ovarian ligaments and the outer extremities of the tubes, followed by incisions in the recto-uterine and utero-vesical folds with separation of the bladder, the uterine arteries of both sides were rapidly divided between Kocher's clamps and the cervix was transversely divided in a similar manner. The child was extracted from the uterus as soon as it had been removed, and after a few artificial respirations breathed normally and subsequently appeared healthy. It is said that in cases in which Caesarean section is contraindicated the use of this operation does not add to the dangers of either mother or child. In order still further to reduce the duration of the period intervening between the total interruption of arterial circulation and the extraction of the foetus Solieri suggests that the operation might be performed in the following order: section of the round and utero-ovarian ligaments, then of the broad ligaments; reflection of the peritoneum in front and behind the uterus; ligature of the right uterine artery; division of the cervix from right to left; and finally, division of the left uterine artery.

515. Variations in the Female Pelvis.

WILLIAMS (*Amer. Journ. of Obstet. and Gynecol.*, April, 1922), from pelvic measurements of 300 primiparous patients, concludes that there are two distinct and easily recognizable types of normal female pelvis, which may be called respectively the feminine and the muscular type. The feminine type presents an intercrural diameter, an interspinous diameter, and an external conjugate diameter of 28 to 29 cm., 25 cm., and 18 to 20 cm. respectively—that is, measurements approximating to those described in the textbooks; these measurements are associated with thin bones, a wide arch, and an ample transverse diameter of the outlet. The second or muscular type is characterized by large external measurements—for example, external conjugate 21 to 25 cm., interspinous 26 to 28 cm., and intercrural 30 to 32 cm.—in association with a narrow outlet, an angular pubic arch, a thick os pubis, and thicker muscles and fasciae. In the muscular type premature rupture of the membranes occurs in nearly 40 per cent. and occipito-posterior positions are relatively common; Caesarean section was more often necessary in patients presenting this type of pelvis.

516. Treatment of Metrorrhagia by Pituitary Extract.

ACCORDING to MOSSE and MAURICE FABRE (*Gynecol. et Obstet.*, 1922, iv, 3) pituitary extract is strikingly successful in the treatment of excessive uterine haemorrhage occurring at puberty or the climacteric. Its efficacy is due to its stimulant action on the uterine muscle, its vaso-constrictor action on the uterine and ovarian vessels, and its inhibitory action on the internal secretion of the ovary. For excessive haemorrhage occurring apart from and between puberty and the climacteric an organic cause is frequently to be found, and the therapeutic indications of pituitary extract are limited; occasionally, however, it is successful in controlling menorrhagia or metrorrhagia of which the cause is obscure, and the writers record a case in which, after administration

of pituitary extract for persistent and inexplicable metrorrhagia in a woman aged 30, an intracervical polypus (the extirpation of which subsequently led to a cure) was found to have presented. The extract is given by injection in the gluteal muscles of 1/2 c.cm. of extract, corresponding to 2.5 eg. of posterior lobe, followed at forty-eight hours' interval by five to seven 1 c.cm. doses. One or two doses injected a few days before the anticipated date of menstruation serve to control the menorrhagia of puberty.

517. Differential Diagnosis of Cervical Cancer and Chancre.

WARTHIN (*Amer. Journ. of Syphilis*, 1921, v) records the case of a woman, aged 42, in whom the cervix uteri was found to be covered by a growth of cauliflower type, friable and bleeding readily, showing in one place an ulceration the base of which was covered by a greyish membrane. The Wassermann reaction was negative, and the growth, which was regarded as a cervical carcinoma, was removed by panhysterectomy. Subsequently the patient exhibited signs of secondary syphilis, and the husband developed signs of similar infection. Suggesting that the woman had contracted syphilis from the needle used in taking the blood sample, they each brought an action for damages against the hospital. Microscopic examination of the growth showed a typical chancre of a few weeks' duration; spirochaetes were also demonstrated. The actions were unsuccessful. The writer agrees with other observers that there are no clinical features indubitably diagnostic of primary syphilitic cervical sore; a microscopic examination is indispensable. The detection of spirochaetes in a smear from the cervix is not conclusive, for, in the absence of local chancre, spirochaetes may be present in the cervical secretion of a subject suffering from syphilis, and a syphilitic woman may have cancer of the cervix.

518. Treatment of Hyperemesis Gravidarum.

FALK (*Zentralbl. f. Gynäk.*, April 29th, 1922), in seven severe cases of hyperemesis gravidarum, found six respond promptly to treatment by hypnotic suggestion; one was refractory. In one patient the treatment was undertaken as an alternative to induction of abortion: the morbid symptoms disappeared completely after the first induction of post-hypnotic suggestion. Fraenkel (*ibid.*) records equally spectacular successes after treatment by application of x rays to the abdomen; it is questionable whether the effect was due entirely to suggestion or to a sedative action of the x rays on reflex excitability.

PATHOLOGY.

519. Encephalitis Lethargica.

LEVADITI, HARVIER, and NICOLAU (*Ann. de l'Institut Pasteur*, February, 1922) state that the ultramicroscopic filtrable virus, the causal organism of encephalitis lethargica, is of variable virulence and may exist in one of four forms: (a) In an attenuated condition in the saliva of healthy individuals, where it appears to be bound to the epithelial cells of the mouth, this attenuated virus being capable of giving rise to keratitis when inoculated by scarification into the cornea of a rabbit. (b) In a more virulent form in the vesicles of herpes, where, in addition to possessing affinity for epithelial cells, it has a latent affinity for nerve cells. (c) In a virulent form in the saliva of carriers of encephalitis lethargica. (d) In the central nervous system of cases of encephalitis lethargica when the virus is possessed of a selective affinity for both epithelial and nerve cells. A virus of feeble virulence, with an original affinity only for nerve cells, may by successive passages through animals be so exalted in virulence that it becomes adapted to nerve cells and thus may give rise to cerebral lesions. The virus of encephalitis lethargica exists in the mouths of healthy carriers, in whom it causes no symptoms, and it is also responsible for such milder diseases as herpes. When by a progressive exaggeration of its pathogenic activity it acquires the new affinity for nerve cells, then epidemics of encephalitis lethargica begin to make their appearance. The salivary virus, the virus of herpes, and the virus of encephalitis are only variants, showing different pathogenicity, of the same organism—the ultramicroscopic virus of encephalitis. A comparison of the properties of the virus of the encephalitis group with the virus of rabies, of poliomyelitis, and the organism of vaccinia shows them to have many characters in common—namely, all are filter-passers, all may be preserved in a dry state or in glycerin, they are all destroyed at about the same temperature, and they can only be cultivated *in vitro* in symbiosis with cellular elements. They

differ in the diseases to which they give rise and in the fact that protective vaccination is only of value against the same species. But all the members of this group have an elective affinity for the ectoderm—namely, the epithelium and nervous tissue, the latter having been derived by invagination of the embryonic ectodermal layer. Thus the organism of vaccinia shows a constant and obligatory affinity for the skin and cornea; the encephalitis virus, as already stated, attacks either the skin or nerve tissue, according to its virulence; the rabies virus behaves in the same way, except that it causes no local lesions and only profits by its affinity for epithelial structure whilst travelling up the nerves to the cerebral centres; the virus of poliomyelitis shows no affinity except for the grey matter of the spinal cord. For these reasons Levaditi suggests that the diseases caused by this group should be designated "the ectodermoses."

520. Significance of the Haemosiderosis of Pernicious Anaemia.

EXPERIMENTAL evidence is brought forward by McMASTER, ROUS, and LARIMORE (*Journ. Exper. Med.*, April, 1922) calculated to throw light on the seat of election for the deposition of blood pigment in the haemolytic group of anaemias. It has long been held that the marked siderosis of the liver parenchyma that occurs in pernicious anaemia is due to the occurrence of pathological blood destruction localized within the portal tributaries. To ascertain whether this is actually the case young rabbits were taken and given varying doses of haemoglobin over a period of several weeks, the injections being made into the subcutaneous tissues. They were then killed by chloroform and sections of the tissues stained for free iron. The chief collections were found in the liver and kidneys, but the extent to which these organs were affected depended on the size of the injection. When this was small only the liver showed change; when a medium dose was given both organs were pigmented; while with large doses the kidneys were far more heavily siderosed than the liver. When only a small amount of haemoglobin is liberated into the systemic circulation, the liver appears to be able to deal with it completely, becoming slightly siderosed in the process. When, however, a larger amount is in circulation the kidney threshold for haemoglobin is passed, the pigment is filtered through the glomeruli and partially absorbed by the tubules, which take up considerable quantities of free iron. If the tubular resorption be incomplete, haemoglobinuria will follow. The conclusion to be drawn from these facts is that it is impossible to locate the site of haemolysis from the organ which contains the greatest quantity of haemosiderin. If these results be applicable to the human being, the gastrointestinal infection theory of the origin of pernicious anaemia is deprived of one of its most powerful supports.

521. Staphylococcal Haemolysin.

ORCUTT and HOWE (*Journ. of Exper. Med.*, April, 1922) observed by chance, during the routine bacteriological examination of milk on blood agar plates, that a particular staphylococcus caused haemolysis when milk was present in the medium, but showed no haemolysis in its absence. This phenomenon was investigated and traced to the fat in milk; it was found also that with other strains of staphylococci no lysis of red cells occurred unless fat was present, but it occurred readily in the presence of fat. The reason for the necessity for fat is attributed to the fact that the staphylococcus produces an extracellular lipase ferment which hydrolyses the fat to fatty acid, and it is this fatty acid which induces haemolysis. This explanation is in accordance with other researches, which have shown that fatty acids or their soaps readily haemolyse red cells. The extracellular nature of the lipase enzyme was proved by the fact that the suspension of staphylococci killed by heat or chloroform still induced haemolysis in the presence of fat. Many fats other than milk fat are acted upon by the lipase with the production of an haemolytic agent, but milk fat proved to be the most suitable for demonstrating the haemolysis, probably because the fat is so well emulsified in milk.

522. The Fat of Adipose Tissue in Malignant Disease.

CURRIE (*Journ. Path. and Bact.*, April, 1922) has made some observations on the changes which occur in the body fat in cases of malignant disease, as a result of which he finds that in both carcinoma and sarcoma—but particularly the former—there is a distinct increase in the proportion of unsaturated fat. The iodine value for normal human fat he gives as 60.8, whereas that for a series of cases of sarcoma studied was 69.8, and that for carcinoma 74.4. If, however, the fat be taken from a point of the body remote from the actual tumour a lower value is found, albeit one considerably above normal. The significance of these observations is unexplained.

"Pitibulin"

Promotes contraction of the inert uterus and, after delivery, prevents post-partum hæmorrhage.

"Pitibulin" post-pituitary solution is physiologically tested and standardised to the highest degree of activity. Injected subcutaneously or intravenously its characteristic action is exerted directly upon involuntary muscle fibre. Thus by constriction of the peripheral arterioles it raises blood pressure, and is therefore usefully employed in shock and collapse. The action of "Pitibulin" upon the uterine musculature comes on a few minutes after subcutaneous injection and is very marked. The degree of contraction of the isolated uterus produced by high dilutions of "Pitibulin" is the basis of one of the physiological methods of standardisation.

Ambulatory Treatment of Fracture of the Limbs; Tuberculous and Arthritic Disease of Joints.

By C. A. HOEFFTCKE, 7, HARLEY STREET, W.1.

Extract (see THE LANCET, May 29th, 1920).

The Advantages Afforded by Extension in the Treatment of Diseased Joints.

By SIR W. ARBUTHNOT LANE, BART., M.S., F.R.C.S., Consulting Surgeon, Guy's Hospital, &c.

"Effect of the Apparatus on the Diseased Joint."

"The advantages afforded by the forcible separation of the diseased articular surfaces from one another, combined with free movement, are best shown by the use of a really efficient extension apparatus for the leg, which does not interfere with the functioning of the diseased joint. This is effected by the apparatus which Mr. Hoefftcke has devised. Not only does it exert great strain upon the articulation, keeping the surfaces from impacting on one another, but it permits of free movement of the joints of the leg, while enabling the sufferer to lead an active life. It keeps the parts well supplied with blood, which flows more freely through the vessels of the affected joint, while the muscles are kept functioning normally.

"The method of cure is based on the same principle as that applied with so much success in the treatment of tuberculous disease of the lungs at the institutions at Frimley and elsewhere. Since I first grasped the great advantage afforded by this principle, best applied by the apparatus already referred to, I have employed it largely with much success. If a diseased joint is moved forcibly without being extended the articular surfaces are bruised or otherwise damaged, and acute inflammation follows only too frequently; whereas under the influence of extension the surfaces of the fixed or displaced joint can be moved freely on one another, so that much movement is followed by a minimum degree of rapidly subsiding inflammation. The apparatus, by means of which a considerable amount of extension is kept up upon the affected joint, is applied to the limb and the patient at once proceeds to lead an active life."

The points I wish to impress upon the reader are that the separation of the deformed articular surfaces, and their painless and free movement on one another which is brought about by the use of my apparatus, restore the form and function of the damaged joint by favouring the formation of new bone and new articular cartilage, so affording the patient a thoroughly useful and efficient limb.

The following description by the patient, a medical man, shows the result obtained by the use of Hoefftcke's Ambulatory Treatment with his Extension Appliances in one of the severest Rheumatoid Arthritis cases; where nearly all joints were attacked.

Dr. C., aged 50, sudden onset with high temperature of general infection Arthritis.

Treated with vaccines, &c., without results for 18 months, also 9 months at Bath, baths, ionization, &c., under Col. B.'s partner.

Condition after 27 months absolutely incapacitated, bedridden, extreme pain in all joints with muscular spasms on sleeping, knees very swollen, painful and contracted.

Came to London and consulted Dr. H. M., who ordered Hoefftcke's Ambulatory Extension treatment.

Cast for splints taken in January, 1916, and limbs put up in plaster to lessen muscular spasm for a fortnight, which it did very effectively.

Splints applied, angle of contraction 55 degrees knee-bar and elastic traction straightened out knees completely within six months, during that time I walked about and had less pain the more I walked, no doubt owing to the increased blood supply in the joints and the formation of antibodies in the blood itself.

When the knees were completely straightened out, the elastic traction was substituted for steel bar traction, which gave additional power in the direction of extension of joints when walking.

After wearing the splints for about six months, I could walk a mile with a fair amount of comfort, and muscular power increased accordingly.

After wearing splints two years, elastic traction was discontinued and flexion and extension was normal.

Right splint was taken off June, 1918, and left splint at the end of 1918.

At the commencement of treatment, there was great muscular atrophy, but when splints were taken off the limbs were nearly normal size.

Hands and arms which were very painful and contracted at beginning of treatment, became more supple as the knees improved.

The splints have now been discarded for two years without re-occurrence, indeed with steady improvement in all joints including the upper limbs, I am now (1921) able to walk, run, and even play tennis.

An Address ON DYSPEPSIA AND THE CONDITIONS UNDERLYING IT.*

BY
LORD DAWSON OF PENN, G.C.V.O., M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

The term "dyspepsia" is not only consecrated by time but by usefulness. It denotes disturbances of digestion mainly referable to the stomach, and due to a variety of causes, some of which reside within and others without the stomach.

With extending knowledge these causes are becoming more clearly defined. Abdominal surgery has disclosed to us the part played by anatomical lesions of the stomach, duodenum, gall bladder, and appendix in the production of dyspepsia. In fact, if we take retrospect of clinical diagnosis we are compelled to confess that our errors have been those of both omission and commission, for on the one hand many dyspepsias thought to be functional have been shown to have a structural basis, and on the other a large clinical group which was formerly styled "gastric ulcer" is now known to be associated with no such demonstrable lesion. The pain after food relieved by vomiting with epigastric tenderness and occasional haematemesis, so often complained of in out-patient departments and surgeries, the subjects usually being young females, was at one time diagnosed as due to gastric ulcer, whereas such a lesion is in these cases the exception rather than the rule. We must look rather for the explanation of such symptoms to chronic catarrh of the stomach associated with infections of teeth, gums, tonsils, sinuses, appendix, or colon. True the infective factor does not stand alone, for stasis in the colon will impair the motor and possibly the secretory functions of the stomach, as will also a sedentary life and badly ventilated workrooms. We know but little of the workings of these infections, but they show the interdependence of the different regions of the alimentary tract.

The physicians of past days—and they were penetrating observers—used to speak of the proneness of typhlitis to occur in patients liable to attacks of tonsillitis, and the association of appendicitis with infected tonsils may be observed with equal frequency to-day. Some years ago I urged the importance of the infective factor in gastro-intestinal disease,¹ and described cases in which the same type of streptococcus had been isolated from the tonsils, stomach, and appendix of the same patient. Further, an interesting report has been published² of an epidemic of severe tonsillitis in a school in which a proportion of the cases developed acute appendicitis. Probably it was a streptococcal infection.

The teeth, gums, and tonsils have been receiving much attention on account of the part infections of these structures are thought to play in the causation of conditions so varied as gastritis, appendicitis, cholecystitis, tonsillitis, arthritis, pyelonephritis, and anaemia. Whereas for years William Hunter and others were as those crying in the wilderness urging the significance of the septic month, now opinion has swung the other way, and teeth are removed with a lightheartedness that calls for protest. No one denies that a septic month is a potent cause of gastro-intestinal disease, and in the severer forms of mouth infection teeth have, so to speak, been removed on their obvious demerits; but in a number of cases teeth not grossly or obviously diseased are removed, and when, as sometimes happens, this sacrifice is followed by no amelioration of symptoms one is driven to inquire whether the last state of the patient is not worse than the first—a view that the victim himself is apt to share. The justification for such procedure lies in the dramatic relief from illness and improvement in health which sometimes follows the sacrifice of teeth. The difficulty lies in our inability to state with confidence that, in a given case, sepsis of the jaws is the cause. Dental and alveolar infection which in one patient is producing definite morbid results, in another is without apparent ill effects. Escape from this clinical quandary has yet to be found. Recent work by Rosenow and others may help towards it.³ These investigations show that focal infections such as those of teeth and gums have a specificity as regards the lesions they produce.† Thus if, in a given patient, tooth or tonsil infection is pro-

ducing gastric ulcer, or appendicitis, or both; and if, say, cultivations from this tooth or tonsil are made in glucose brain broth; and if, again, from this culture a rabbit is inoculated intravenously, at the end of a few days this rabbit will show gastric ulceration and inflammation of the appendix due to the same organism—in short, the lesion has bred true from the patient to the rabbit. If these ingenious investigations receive confirmation the actual responsibility of mouth infection in any given case might be determined, and treatment become more rational and secure.

Again, in dyspepsias directly caused by a diseased appendix and cured by its removal, the distal portion of such an appendix may be a definitely infective focus as shown by its walls and contents. Though sometimes presenting themselves in capricious guise, dyspepsias in their clinical manifestations broadly fall into three groups:

I. Pain or discomfort thirty to forty minutes after food with epigastric tenderness. Vomiting, if present, follows the pain and relieves it. Haematemesis is an occasional feature.

II. Pain two to three hours after meals (it may be with tenderness) relieved by food and alkalis—the hyperchlorhydria complex.

III. Distension and flatulence are the dominant features, and the discomforts which go with them. Vomiting and bleeding do not occur. The bowels are liable to act irregularly and incompletely.

With regard to these groups of symptoms, each of them may be associated with a structural lesion, and at other times no such demonstrable lesion is present.

The typical lesion that is suggested by the first group is gastric ulcer, by the second group duodenal ulcer, and by the third group a diseased gall bladder, and all three groups may be associated with a diseased appendix.

GROUP I.

The first group has a large representation among young women, whose pale and sallow complexions, due to anaemia and constipation, one readily recalls. It is these patients who formerly swelled the statistics of gastric ulcer and accounted for the mistaken view that gastric ulcer was easily curable by rest and milk diet. The reason why the results were so good was because the patients were not suffering from ulcer. No doubt a few have ulcer and more a diseased appendix, but the majority have no anatomical lesion, and their symptoms are due to a non-functioning colon, to faulty liver metabolism and (possibly as a consequence) excretion of toxic products into the stomach; or, in other cases, to infection from gums, pharynx, or tonsils. May I say in passing that, apart from any necessary local treatment, these cases are a strong plea for the open-air ward. They do not do well in town hospitals, but recover as if by magic with rest and graduated exercise in the open air. They bring to our minds not only the unsatisfactory results, but the economic waste of treating many diseases in expensive town hospitals, from which the patients should be transferred to the country as soon as the diagnosis has been established.

A clinical picture conforming to Group I may present considerable difficulty in diagnosis, and to this I will recur later; and here arises the significance of haematemesis. It has been shown conclusively that bleeding from the stomach does not necessarily denote any demonstrable lesion. Considerable haemorrhage may have one or several points of origin: in some instances erosions may be observed, in others not even these. The same phenomenon is observed in the uterus. On the other hand, bleeding originating in the duodenum is nearly always associated with an anatomical lesion.

A few words on the treatment of severe haematemesis. The difficulty of saying whether there is an anatomical lesion, and if there is such the considerable operation needed to deal with it, the bloodless patient, the dilemma either of moving him or of operating in unfavourable surroundings, combine to present us with a perplexing problem. Exceptions apart, there is a better prospect with absolute rest, morphine, an icebag, and haemostatic serum.

GROUP II.

Hyperchlorhydria may be due to many causes. It is associated with duodenal ulcer, and less pronouncedly with gastric ulcer. It is caused by lesions of the appendix and of the colon, and by functional disturbance of the latter. It may have a central origin and be the expression of overwork and the anxiety of the highly strung temperament, or it may fall into the category which is called "gouty."

* Delivered before the North Staffordshire Medical Society.

† It may be that sympathetic ophthalmia is similarly explained.

Contrasted with the other two groups a larger proportion of the cases (hyperchlorhydria complex) will have a structural basis, and if a diagnosis of functional disorder is made it will need to be periodically passed under review. Moreover, the picture of duodenal ulcer is in its entirety well defined.

GROUP III.

Cases comprised in Group III, in which distension and flatulence are the prominent features, are the most difficult to sift because the symptoms are manifestations of such a variety of conditions. Thus "fatigue" dyspepsia, the abdomen over-responsive to mental stress and strain, colitis, myocardial insufficiency, anaemias, hyperthyroidism, may show similar gastric manifestations. Side by side with these are the diseased appendix or gall bladder, which if removed would cure the patient.

No doubt careful investigation often enables correct discrimination to be made, but it must be confessed that not infrequently the evidence is too vague for us to be confident in our diagnosis, and removal of the appendix under such conditions sometimes results in disappointment.

In those doubtful cases in which there is no direct evidence of appendix disease let me suggest that the more purely gastric the manifestations the better the chance of success from operation, whereas the association of disturbed action of the colon and the passing of mucus should suggest doubt as to the wisdom of surgical interference.

Appendicitis Mimicking Gastric Disease.

A diseased appendix may be the underlying cause of any of the above three groups of symptoms, and it will sometimes mimic with extraordinary accuracy the picture of gastric and duodenal ulcer. The distinctive features of the clinical picture of ulcer, and especially of the duodenum, are orderliness and periodicity. The time relation of the pain-food sequence is constant, and, except in cases of long standing, there is complete freedom from symptoms between the attacks, which will sometimes come and go with suddenness and without reason. On the other hand, in the hyperchlorhydria complex due to a diseased appendix the time of occurrences of pain after food will be more variable, and between attacks there is seldom complete freedom from symptoms—the patient is usually more or less of a dyspeptic.

Turning to the way in which a diseased appendix sets up gastric symptoms, there would appear to be two factors—namely, the reflex interference with gastric function, and infection. An example of the former is to be seen with the fibrotic appendix, the lumen of which is more or less obliterated; an example of the latter is an appendix which, a short distance from its proximal attachment, becomes enlarged, and it may be bulbous, its mucous membrane thickened, and the contents purulent.

The fibrotic appendix is often found in the cases which resemble the ulcer picture. Keith and others have demonstrated the correlation of function of the ileo-caecal and pyloric regions. Moynihan pointed out that in chronic disease of the appendix the pyloric region of the stomach, including the sphincter, may be seen at an operation to be in a state of spasmodic contraction. The appendix, through the nerve mechanism of the ileo-caecal region, causes an excessive secretion of hydrochloric acid and motor irritability of the stomach wall. What the further or underlying agency is that causes ulcer to form we do not know. In the opinion of some investigators, it is a focal streptococcal infection.

Radiography.

With the acknowledgement of certain difficulties in diagnosis from clinical evidence alone it will be well to consider how far investigation by radiography and test meals will aid us in the types of cases just described.

We gain from radiography knowledge of the character and speed of gastro-intestinal movements and sometimes actual demonstration of pathological changes. These movements will, in a measure, depend on the substance employed. Thus barium sulphate, often used on account of its moderate cost, stimulates stomach action, whereas bismuth compounds rather retard it, with the result that barium leaves the stomach nearly twice as fast under like conditions as bismuth. It likewise travels more quickly through the small intestine, but in the large intestine the times are the same.

The following time-table of a barium meal is based on Groedel's observations of the normal stomach with a meal consisting of barium sulphate 250 grams, maize flour 20 grams, sugar 20 grams, chocolate or cocoa 20 grams, water 400 c.cm.

The times are approximate; emptying of the stomach varies with the composition of the meal.

Stomach empties	1½–2 hrs.
Caecum reached	1–1½ "
Hepatic flexure reached	2–6 "
Splenic flexure reached	4–8 "
Rectum reached	24 hrs.

or

- 1 hour after a meal: Stomach emptying; small intestine visible; caecum may have begun to fill.
- 2 to 2½ hours: Stomach empty; caecum filled.
- 4 hours: Small intestine empty; ascending colon filled.
- 10 hours: Large gut filled to splenic flexure.
- 24 hours: Large gut filled to rectum.

The normal stomach may show variations in shape, position, and size. The shapes vary according to the muscular tone—namely, orthotonic, hypertonic, hypotonic, atonic. A stomach of normal tone holds up a considerable column of contents in its vertical portion. With less tone the vertical portion holds up proportionately less and the horizontal portion more of the meal.

The cap—formed by the distended first part of the duodenum—has in health a characteristic shape and smooth outline, and a defect in shape and outline is evidence, though not conclusive evidence, in favour of a pathological condition, such as ulcer, adhesions (for example, from cholecystitis), or pressure from an adjacent organ. On the other hand, a normal cap is evidence of value—it is, for example, against the existence of a chronic ulcer.

An opaque meal may give direct demonstration of an ulcer, fragments of bismuth being projected from the main bismuth shadow into the depression or crater of an ulcer. This method of investigation in the hands of those who have developed the requisite technical skill possesses a great and increasing reliability. As illustrating this, in one of my cases a duodenal ulcer had been diagnosed on clinical grounds. Dr. Vilvandre, from the bismuth shadows, expressed the opinion that there was not only a duodenal ulcer but a further ulcer near the lesser curvature, and this view was confirmed at operation.

An opaque meal may likewise give direct evidence of a growth owing to a deficiency of the shadow or a raggedness of edge. Such appearances would, however, portray a growth of some standing. With an early stage of growth radiography seldom helps, and its negative conclusions must not be allowed to give us false security or deter us from action.

Motility is conveniently considered with the emptying time of the stomach: under normal conditions it is about one and a half to two hours for a barium meal. In digestion the time of emptying depends on the substance swallowed. Thus with water it would be about an hour; with light gruel two and a half hours; with full milk four hours, skimmed milk two and a half hours. Fats always delay emptying. Delayed emptying may result from pyloric obstruction, either of the spasmodic or organic type, and from weak motility, which may have its cause in the stomach wall (atony) or be associated with disease of appendix, colon, or gall bladder, or, again, with heart and other diseases.

Rapid emptying may be due to irritation from acute gastric catarrh, from ulcer or early growth of stomach, from ulcer of duodenum, from certain cases of chronic appendix, hyperchlorhydria, disease of colon, hyperthyroidism, and irritability due to nerve strain, etc. It is thus seen that inferences from rapid emptying must be made with caution.

A chronic appendix with the dyspeptic manifestations conforming to Groups I and III described above would most often be associated with delayed emptying, whereas as regards Group II the emptying would be accelerated. Often hyperchlorhydria has a tendency to accelerate and an associated spasm of the pylorus to delay emptying. As regards duodenal ulcer, emptying may be hurried in some cases and not in others. Tenderness on palpation over the stomach and duodenum during radiographic examination may easily be misleading.

Test Meals.

The technique of test meals has been improved by enabling the contents of the stomach to be analysed at intervals during digestion instead of only once—for example, an hour after ingestion.

An adaptation of the Einhorn tube is employed. The patient swallows this into an empty stomach. By means of a syringe samples can be withdrawn. The fasting contents are first examined, then the patient swallows, with the tube in position, one pint of a thin test gruel, and samples of the contents are withdrawn at intervals of a quarter of an hour.

and examined, and their free and total acidity determined in terms of a decinormal soda solution, and charted. The presence of pepsin, mucus, bile, and blood, the time of their appearance and disappearance, and the time of emptying of the stomach can be recorded.

If it is desired to investigate the stomach bacteriologically the fasting content can be examined in films and by culture. Cases comprised under Group II least often, and those under Group III most often, disclose positive results.

To examine the duodenal contents the patient lies on the right side as soon as the tube has entered the fasting stomach, and in due course the tube will enter the duodenum, which can be established by the fluid becoming alkaline and by x-ray examination. Also a certain grip is felt when the tube is in the duodenum.

The normal stomach shows on average a maximum free acidity of 30 (0.109) and a total acidity of 50 (0.182). In contrast with this a duodenal ulcer may give a free acidity of 70 or more, and a total acidity of 80 or 90; an acidity which is associated with rapid emptying—say in an hour—is less sustained than an acidity which is associated with emptying in two and a half hours. On the other hand, there is the absence of free acid and the low total acidity (10 to 30) found in malignant growths, pernicious anaemia, and other conditions.

MALIGNANT DISEASE OF THE STOMACH.

When it is recalled how large a proportion of cancers arise in the stomach (according to some authorities 50 per cent.), and when it is realized that operative treatment of stomach cancer in its early stage is followed by encouraging results, the importance of the recognition of this condition is patent.

In its early stages the manifestations are vague, and there may be an entire absence of symptom or sign till the disease has advanced so considerably as to be incapable of effective treatment. It follows, therefore, that close attention needs to be paid to ill-defined dyspeptic symptoms, and especially in people whose digestions have hitherto been strong. Constant watch and systematic investigation should be the rule. And in patients whose general health is deteriorating a systematic search for the cause should include an investigation of the stomach even though gastric manifestations may be absent.

Well-defined pain is seldom an early feature, and here is a distinction from ulcer. There are often distension and discomfort, but not often pain. Even later there may be a considerable infiltration of the stomach with growth, and yet but little pain.

Vomiting is seldom an early sign, though it may be one of the first signs of a pyloric cancer. Haematemesis may be the first intimation that anything is wrong, though in such cases the growth is seldom found to be early. A tumour that can be clinically detected must never be expected.

A dilated stomach may be the first though not an early sign. Loss of appetite is valuable evidence, and sometimes occurs early, though in other cases a good appetite endures till late in the disease.

Anaemia may attract attention and be a feature of vaguely declining health, and the similarity between the manifestations of malignant disease of the stomach and those of pernicious anaemia are well known. There is often, too, a depression and gloominess of outlook which are suggestive.

A physician rightly puts reliance on his intuition in these doubtful cases, and is thus prompted to proceed to further investigation. The examination of fasting contents, of a test meal in the manner already referred to, the search for occult blood, will afford evidence of value.

As already stated, radiography must not be expected to yield positive assistance in the diagnosis of early stages of malignant growth, unless the latter begins as an ulcer. Perhaps when it becomes practicable to study radiograms serially at short intervals, earlier detection may become possible. If, however, an early growth is situated at the pylorus, radiography may afford evidence of its effects. At a later stage growth near the pylorus may cause a defect in the filling of bismuth. The defect may be annular in shape and appearance, or the growth may cause a "biting out" of the bismuth and an irregularity of its outline.

In this kind of investigation bismuth is better than barium because it stays for a longer time in the stomach and is not stimulating to the movements of the latter.

If the results of the foregoing investigations, carefully considered, lead to the conclusion or even the suspicion that malignant disease may be present exploration should be advised, and although this line of action sometimes will lead

to negative results and unnecessary operations, this is of far less importance than the missing of an early carcinoma in a situation where removal can offer favourable prospects.

EFFECTS OF CHRONIC STARVATION DURING THE SIEGE OF KUT.

BY

MAJOR-GENERAL SIR PATRICK HEHIR, K.C.I.E., C.B.,
C.M.G., I.M.S.

LATE A.D.M.S. 5TH (POONA) DIVISION.

THE siege of Kut lasted 148 days, from December 4th, 1915, to April 29th, 1916. The besieged garrison consisted of the 6th (Poona) Division, supplemented by various details. The strength on December 8th, 1915, was 14,586; this included British officers 218, British rank and file 2,534, Indian officers 175, Indian rank and file 8,117, followers 3,542. Of this number 1,503 were sick and wounded in hospital.

The following notes were prepared with the view to placing on record the state of nutrition and general health of the Kut force during the penultimate week of the siege—April 11th to 18th, 1916; they were completed and submitted to the G.O.C., Major-General Sir Charles Townshend, K.C.B., D.S.O., on April 28th, the day before the capitulation. They are published now for the first time. As may be understood I was not in a condition of health and strength to take full advantage of the material at my disposal; even this meagre record called for some effort of will. The siege afforded opportunities for studying the morbid state of the body brought about by long-continued deprivation of an adequate quantity of suitable food which seldom present themselves; it would have been almost criminal to have disregarded them.

During 1915 the 6th (Poona) Division experienced severe hot weather and an epidemic of malaria in Lower Mesopotamia, and immediately before the siege underwent great physical strain and exceptional hardships on the march to the battle of Ctesiphon, during the battle (November 22nd to 24th, 1915), and in the retirement from Ctesiphon to Kut, where they arrived in a worn-out state on December 3rd, 1915. During the early days of the siege the preparation of the defence works threw a considerable amount of labour on the troops. It was in the circumstances considered advisable to let them build up part of their tissue losses for a week or so before beginning to reduce their rations; this reduction was then made gradually. Most of the garrison were in trenches and dug-outs; the remainder were billeted in huts or bivouacked, or were in tents with the floors sunk several feet.

Meteorological Conditions.—During the months of December and January and the first half of February it was decidedly cold; from January 15th to February 8th it froze every night. The ill effects of the cold were intensified by high winds and rain storms. From January 17th to 20th the trenches were flooded with ice-cold water. On January 20th twenty-four Indians were brought out of the front trenches collapsed from the cold, and were resuscitated with much difficulty; five others were found to be dead—cold and stiff. After the middle of February warmer weather set in.

The Rations of the Kut Garrison.

To grasp the state of nutrition of the garrison towards the end of the siege it would be well to bear in mind the usual classification of foodstuffs, the physiological bases upon which rations for bodies of men such as soldiers are formulated, and the functions carried out by each class. The rations of the British soldier in Mesopotamia before the siege had a heat equivalent of 3,600 calories, that of the Indian 3,100 calories.

The Protein Factor.—British troops did comparatively well as regards their protein ration during the siege. When fresh beef and bonilli were exhausted they were given 1 lb. of horse-flesh, which was increased to 1½ lb., next to 1½ lb., and then to 1½ lb., but finally reduced to 1½ lb. again. While the ration of bread was not below 10 oz. and the butter and bacon continued, this amount of horseflesh prevented any rapid loss

of weight and stamina, but when the loaf was reduced to 8 oz. and all butter and bacon ceased, they began to lose flesh and condition rapidly—the oxidizable material in the bread and horseflesh combined was insufficient, and they started using part of the protein of their muscles for the production of force and maintenance of the temperature of the body. In Indians, except those who had eaten horseflesh from the beginning, the muscles began to waste rapidly as soon as *ghi* underwent a serious reduction, and in all except those who were highly developed physically at the beginning of the siege the muscles dwindled considerably.

The Hydrocarbon Factor.—From a physiological point of view the most serious deprivation suffered by British troops was the absence of hydrocarbons. Bacon and butter failed at a comparatively early stage of the siege. In ordinary circumstances this would have been to some extent compensated for by the large ration of horseflesh allowed, and at the beginning this was so, but during the last ten weeks of the siege the animals themselves were in such a state of starvation that no fat remained in their tissues. They could not go out to graze, as we were within gun and rifle range of the enemy on three sides. From about the end of March British troops were definitely in a state of partial starvation, and were losing ground daily; they were lacking in energy, debilitated, and incapable of any serious strain. The Indian troops received a progressively reduced ration of *ghi*, which was only 1 oz. daily from March 11th, and ceased altogether early in April. Until the second week in April only about one-ninth of the Indians were eating horseflesh, so that the small amount of fat obtained from this source is almost negligible. Indian troops had by that time reached an advanced stage of chronic starvation; their energies were markedly reduced, they were debilitated, less capable than the British of any severe physical strain, and they possessed little resistance to disease.

The early stage of the siege at which the fats and carbohydrates of the rations of British troops and Indians had to be reduced soon led to a loss in body weight, which was naturally to a large extent at the expense of the adipose tissue of the body. There were some men who began the siege in a highly muscular state and with a fair covering of fat, who did not show any serious signs of diminution in bulk, but in the vast majority it may be stated that a large part of their body fat had been burnt up by April 15th; many British troops were decidedly attenuated, especially among the younger men, while about 10 per cent. of Indian troops and followers were really emaciated.

The Carbohydrate Factor.—The greatly reduced ration of the garrison in carbohydrates (the average reduction of bread in British troops during the five months of the siege was 50 per cent., and of the *atta* of Indian troops 66 per cent.; during the last six weeks neither sugar, *gur*, butter, nor *ghi* was available) led to the removal of nearly all glycogen from the liver and muscles, so that the amount of stored material readily assimilable in the tissues for energy and heat production during the penultimate fortnight of the siege was at a minimum. This fact was demonstrated by the case with which the men became fatigued, their inclination to remain at complete rest whenever opportunity offered, and the speed with which they collapsed, with a marked sub-normal temperature, when they had the misfortune to get an attack of diarrhoea or any other malady causing a drain on the system. It likewise helped to explain how difficult it was to restore the heat of the body once it was lost. British troops especially felt the want of more bread, which forms a large part of their food normally; they also had urgent cravings for fats and sugar; there was a very marked yearning for tea. In the same way Indians had a great longing for more *chuppatties* and *gur*.

Inorganic Salts.—Shortage of salt in the rations of both British and Indian troops and followers began about the middle of the siege, after which time the salt issue underwent great reduction, the troops receiving only about one-eighth the normal ration. Early in April it ceased altogether except for a small issue made for a few days from some bags of salt that were dropped into Kut by aeroplanes. I was not able to gauge satisfactorily the extent to which this deprivation affected the nutrition and health of the troops. It is possible that some of the cases of diarrhoea and gastro-intestinal disturbance that prevailed during the last two months of the siege were partly attributable to a want of sufficient salt in the food.

It is well to bear in mind the very important differences between acute starvation, in which there is complete and

sudden deprivation of all food, and chronic starvation such as we went through, in which there is continuous use of an insufficient supply of food of a kind unsuitable to maintain the normal standard of nutrition. In acute starvation until death actually happens it is possible to restore the victim to health and strength once more by an appropriate regimen; in chronic starvation a stage is eventually reached, sometimes weeks before death, from which recovery is impossible.

The following lists give the quantities of the various articles of diet used by the Kut garrison, and show the progressive reduction of some and disappearance of most of them from the rations in the penultimate and final stages of the siege.

Tables of Rations issued during the Siege.

On January 22nd, 1916, and for some weeks after, the rations consisted of:

British Troops.		Indian Troops and Followers.	
Bread, white	12 oz.	Atta	8 oz.
Meat	8 "	Rice	8 "
Butter or cheese	3 "	Gur	1 "
Potato meal	2 "	Ghi	2 "
Pickles	1 "	Ginger	1 "
Jam	3 "	Dhal (lentils)	2 "
Dates	2 "	Chillies	1 "
Tea	1 "	Garlic	1 "
Sugar	1 "	Dal	3 "
Salt	1 "	Potato meal	2 "
Ginger	1 "	Salt	1 "
Fuel	2 lb.	Fuel	1 lb.

On March 11th, and for some weeks afterwards, the rations consisted of:

British Troops.		Indian Troops and Followers.	
Brown bread	10 oz.	Barley flour	10 oz.
Horseflesh	1 1/2 lb.	Barley, unhusked	4 "
Jam	1 oz.	Ghi	1 "
Salt	1 "	Salt	1 "
Oatmeal	2 "	Horseflesh (to those who eat it)	8 "

This British diet is equivalent to 1,975 and the Indian to 1,550 calories. Up to April 12th the heat equivalent of the Indian rations in non-meat eaters was:

Barley flour	10 oz.	700 calories.
Barley, unhusked and parched	4 "	240 "
Ghi	1 "	65 "
Herbs (grass, etc.) as vegetables	4 "	40 "
Total		1,045 calories.

The rations from April 12th onwards with their heat equivalents were:

British Troops.		Indian Troops and Followers.	
Brown bread	6 oz.	Coarse barley flour	5 oz.
Lean horseflesh	2 1/2 "	Lean horseflesh	12 "
Green stuff, herbs, and grass	2 "	Green stuff, herbs, and grass	4 "
Total		Total	
	1,850 calories.		350 calories.
			720 "
			40 "
			1,110 calories.

Up to April 8th only about 1,000 out of over 10,000 Indians were eating horseflesh; on April 14th 9,239 Indians were consuming it. In British troops, after the first fortnight of the siege, the bread ration was reduced to 12 oz., six weeks later to 10 oz., then to 8, and in the last weeks to 6 oz. For about four weeks fresh beef was issued, then bouilli beef or mutton for three weeks, then fresh beef of battery bullocks, after which horseflesh was commenced. Fresh vegetables, potatoes, and onions ceased early in February, but a ration of potato meal was continued for about a fortnight later. Butter and bacon were reduced at an early stage and ceased about the middle of February. The jam ration was very gradually lessened and ceased at the end of March. Tea and sugar were exhausted after the second week in February, then dates replaced the sugar for a fortnight.

In Indians who ate it the fresh meat ration was cut down to 6 oz. after the first week of the siege, later to 4 oz. At the end of the first week the *atta* (coarse wheaten flour) was reduced to 1 1/2 lb., then to 1 lb. with 6 oz. of parched unhusked barley; later to 8 oz. *atta* and 8 oz. rice, then to barley flour 10 oz. and 4 oz. parched barley, and finally to 5 oz. barley flour only. During the first week of the siege the full ration of 2 oz. of *ghi* (clarified butter) was given, then for a month 1 1/2 oz., for another month 1 oz., for two months 1/2 oz., and during the last two weeks none. For the first week of the siege the full ration of 4 oz. *dhal* (lentils) was given, then it was reduced successively to 2 oz. and 1 oz., the issue ceasing at the beginning of March. *Gur* (jaggery or unrefined sugar) ceased about the middle of March, when its place for a fortnight was taken by an issue of dates.

During the first ten weeks of the siege the billeted part of the garrison was able to supplement the rations issued by purchase of barley cakes fried in fat sold by Arab confectioners, also small quantities of *atta*, barley flour, *dhal*, sweetmeats, and dates. These gradually disappeared from the market, and for the last six weeks only negligible quantities of eatables were purchasable. The heat equivalents of these fortuitous foods were not estimated.

as nothing approaching accuracy could have been obtained. These supplementary additions, however, were of significant value to the garrison.

On April 25th I noted: "On an average fifteen men are dying daily; of these, five a day are dying from the direct effects of chronic starvation, and ten from chronic starvation with diarrhoea, bronchitis, or some other simple malady supervening. The present condition of nutrition and health of the average man of the garrison is physiologically highly unsatisfactory. His stamina is greatly lowered, his resistance to disease-causes considerably reduced, and should he suffer from any disease, such as pneumonia or bronchitis, fever from any cause, dysentery, or severe diarrhoea, it will greatly tax his vital powers."

Loss of Weight in Chronic Starvation.—During the nineteenth week of the siege I had the weight of 400 healthy British and 800 healthy Indian troops at duty taken with the view to ascertaining the average loss during the siege. The weights were taken on the same scales, at the same time in relation to meals, and in the same kind of clothes. British troops on an average lost 12.5 lb. per man and Indian troops 17 lb., which was, roughly, a loss of 10 per cent. in weight in the former and 14 per cent. in the latter. Personally I started the siege weighing 10 st. 6 lb., and at the end of it weighed 8 st. 11 lb.; my normal weight is 10 st. 12½ lb. The loss of weight reached its maximum in officers and men who began the siege with a superabundance of fat, and it may be remarked that they stood the loss well. The average loss of weight given above was that which occurred during the siege. It may not appear excessive, but, as stated in the introduction, the force had immediately antecedent to the siege lost a certain undetermined amount of weight from hardships and privations. The average weight in one platoon of Rajpoots on April 16th was 7 st. 12 lb., and in one of Jats 7 st. 10½ lb., as compared with their normal weights of 9 st. 3 lb. and 9 st. 1 lb. respectively.

Lowering of Body Temperature in Chronic Starvation.—In chronic starvation the temperature tends to fall very gradually. The temperature of healthy British and Indian troops during the three days April 17th, 18th, and 19th, 1916, was lower than normal. The average morning temperature in 200 British troops was 96.13° F., and in 260 Indian troops 95.84°. The average evening temperatures in the same men were: British 97.41°, Indians 97.03°. These observations were accurately made and the usual precautions to eliminate error adopted. In some cases in hospital the temperature was less than 90° F. just before death. We had Indians going about at duty with temperatures between 94° and 95°. My own temperature was never above 97° for the last six weeks of the siege, and during the last fortnight it varied from 96° to 96.8°. I was seemingly in good health, but the effects of short commons. We did not meet with the great diurnal variations or fluctuations of body temperature that have been recorded in some cases of acute and chronic starvation.

On April 17th I wrote: "The present condition of the average officer and fighting man who began the siege in fair physique and with a normal deposit of adipose tissue, and who has not suffered from any disease nor been able to supplement his rations from any exceptional sources, may be described as follows: He has lost weight, in particular his muscles have materially decreased in size and about 50 per cent. of his adipose tissue has disappeared; he is much below par in stamina, and, without feeling any decided weakness, he is incapable of doing anything approaching the normal amount of physical or mental work; in moving about his lower limbs feel a trifle heavy; he tires comparatively soon and welcomes a rest after an outing, walk, or short spell of fatigue duty. During work he is disposed to be affected by a temporary giddiness, especially on bending down or after an effort demanding some physical strain, and he perspires more readily than usual. Whilst he does not suffer in any way, he has the usual sensation of emptiness felt about the epigastrium, which is temporarily alleviated by a meal, especially a warm one. His temperature is a few degrees below normal, and his pulse rate from 8 to 10 beats per minute slower than normal. He sleeps well, completely digests what he eats, his bowels are regular; in practically every one there has been an occasional attack of simple diarrhoea which is evanescent. This latter may be connected with the coarse bread or *chuppatties*, and use of such extraneous articles of food as the green herbs and grass collected for vegetables. On the ration now being continued for some time, but at the should be very reduced in weight and much physical exertion. A certain undefinable proportion of the garrison will reach this latter stage long before a month's time; some have reached it already, and a progressively increasing number will reach it from now onwards."

During the last month of the siege men at fatigues, such as trench-digging, after ten minutes' work had to rest a while and go at it again; men on sentry-go would drop down from syncope (the spell of this duty had to be reduced to one hour instead of two); those carrying loads would rest every hundred

yards or so. In many instances Indians returning in the evening after lying the trenches all day, seemingly with nothing the matter with them, would be found dead, cold, and stiff in the morning, death being due to exhaustion of the vital processes resulting from starvation. I saw one dead man lying on his back with a *chuppattie* in his hand near his mouth. It was natural that men in such a low state of health and vitality could stand little in the shape of illness—an attack of simple diarrhoea, for instance, that would have been got rid of in a day or so at the beginning of the siege in March and April often ended fatally; all recuperative and rallying power had gone. Personally up to the middle of March I could make a complete round of the front line trenches and fort (about five miles) in the morning; I had then to halve it, and at the end of April while doing the half I had to take it very quietly, and even then rest every 200 yards or so; practically all officers were in a similar condition of physical incapacity.

Inclination to Sleep in Chronic Starvation.—During the last days of the siege there was an increased tendency to sleep, a greater lowering of temperature, and a still slower pulse rate. If any disease (such as severe diarrhoea) intervened, these phenomena were exaggerated and death rapidly ensued. During the later periods of slow starvation there is practically no actual suffering even when such a disease as dysentery is present. In fatal cases so imperceptibly does life ebb away that it is sometimes not easy to say whether the man is really dead or not.

Reduction of Pulse Rate in Chronic Starvation.—It is sometimes stated that the rate of the pulse continues practically normal until a few days before death from chronic starvation. This is not the case. In the nineteenth week of the siege the average pulse rate in 200 odd cases in whom observations were continued thrice daily for a week was nine beats less per minute than normal. After the middle of April in many men the pulse rate was suddenly increased on the occurrence of impending danger, during an attack by the enemy or an exceptionally severe strafing from aerial bombs or even small-arm fire. The same occurred during severe exercise. A very slow pulse rate, from 30 to 40 per minute, was met with in many cases, both in hospital and at duty.

Mental Attitude of Garrison during the Siege.—During the first two months of the siege both British and Indian troops were moderately cheerful; for the next six weeks or so they were more subdued. For the last month without being depressed or melancholy they became somewhat cheerless, and during the last fortnight manifestations of mirth and vivacity had disappeared. Personally I was astonished at the patience and fortitude with which the garrison endured the terrible hardships they went through. I was amongst the men practically every day from the beginning to the end of the siege, and write from intimate knowledge of the conditions. The grit shown by our British and Indian soldiers was beyond all praise. "The behaviour of the men in meeting the unfortunate circumstances in which they are placed is heroic" (Diary, April 25th, 1916).

CHIEF DISEASES DURING THE SIEGE.

Diarrhoea.—This was by far the most prevalent disorder met with during the siege. On April 16th I entered in my diary:

"During the last two months there has been a high incidence of diarrhoea. In March this disorder was of a mild type and the vast majority of cases were treated regimentally, a few days' rest and medicine rectifying the disturbance. Early in April we began getting cases of very watery and severe diarrhoea with vomiting, cramps in the legs and abdomen, profound prostration, subnormal temperature, pulselessness, suppression of urine, and collapse. The majority of these cases rallied, but many of them became intensely collapsed and died on the second, third, or fourth day. Some after a feeble attempt at reaction, most of them without manifesting any disposition to recover. I have seen practically all these cases; they were not true Asiatic cholera, though clinically very like it. It is not infectious; none of the attendants so far have been affected, and it occurs scattered in platoons and not in groups. The stools have not the well-known rice-water characters of cholera; they always contain a certain amount of bile; there is not the same degree of shrinking of the features, nor the change in the voice met with in cholera, and the mortality is much lower than in that disease. In a large number of instances the stools were examined by a bacteriologist expert, Captain H. H. King, I.M.S., and in none were cholera spirilla discovered."

The essential cause in all these cases was chronic starvation. The men had got into such a state of debility and wasting from shortage of food that any added strain on the economy, such as diarrhoea, was sufficient to lead to speedy dissolution. The disease continued epidemically after we got to the prisoners' camp, Shamran, where during May we had

over 1,500 cases and about 200 deaths from it. I was of opinion that the vast majority of these were ordinary cases of diarrhoea in men whose resistance had disappeared, whose stamina was greatly lowered, and whose heat-generating powers were so reduced that once a drain of any kind occurred from the body they were incapable of rallying; the low state of vitality, and especially the absence of any fuel in the system, rendered resuscitation impossible or highly improbable. The condition is one of the common accompaniments of every lasting famine in India, and has during these famines been repeatedly mistaken for genuine cholera. In the terrible and widespread famine of 1877-78 in India this form of diarrhoea was responsible for the death of most of the famine-stricken.

Dysentery.—A large number of diarrhoea cases merged into a form of dysentery that might pathologically be called catarrhal. The total number admitted into hospital with the clinical symptoms of dysentery was 684. There was besides a large number of slight cases treated regimentally; it might indeed be stated that it attacked a very high percentage of all ranks of the garrison at one time or another during the siege. It was relatively more frequent in Indian than British troops, and was of less severity and associated with a lower mortality and more amenable to treatment in the latter. Pathologically it varied in its intensity from a mild catarrhal inflammation to widespread destruction of the large bowel, and even of the lower part of the small intestine. In the penultimate and final stages of the siege medical officers were unanimously of opinion that the disease did not yield to treatment as satisfactorily as in the earlier stages. The symptoms and course of the disease were something like those of bacillary dysentery, but its real bacteriological relations, if any existed, were not determined. This condition was a particularly fatal terminal complication of scurvy.

Chronic Starvation Debility.—There are reasons for considering that there is a definite pathological state with a fairly well defined clinical course in chronic starvation debility. A general weakness without any assignable cause except the defects in the rations was naturally the commonest condition met with in the siege, and finally affected the entire garrison. It assumed graver forms in Indians than in Europeans. We noticed in hundreds of Indians that there is a stage in the downward path in chronic starvation from which recuperation cannot take place, that after the effects of starvation had reached a stage that is difficult to define, recovery was hopeless, as no possible measures appeared to have the power of restoring the victim. It is a condition of inanition in which it might reasonably be declared that all capacity to assimilate food has permanently disappeared; the glands and tissues engaged in the digestion and assimilation of food have wasted so much as to cease to function, the atrophy of these glands and tissues arising from their disintegration in helping to keep life going. This stage may or may not be associated with the diarrhoea or dysentery alluded to above; in many cases it passes almost imperceptibly into death. When soldiers doing their ordinary duties during a siege are living on less than a mere subsistence diet changes are occurring in their assimilative organs and tissues which, if continued, will lead inevitably to death. The pathological processes in operation in chronic starvation indicate that if relief is to be of service to the victims it should be commenced before the stage under reference has been reached. Enough has been said to indicate that advanced chronic starvation is necessarily associated with a very high mortality.

Scurvy.—Indian troops went through a serious outbreak of scurvy; during the siege it caused 1,050 admissions. A few cases appeared early in January; the incidence gradually rose, and in the middle of January we had 140 cases in hospital; at the end of March there were 597 cases under treatment, after which time it gradually declined. These do not include the incipient undeveloped cases which for military reasons were obliged to keep at duty, nor the latent cases. With the exception of chronic starvation itself nothing undermined the stamina of the Indian troops more than scurvy.

The essential differences between the diet of British and Indian troops were that British ate horseflesh and Indians until near the capitulation did not; Indian troops used *dhal* and British did not; British used white flour or biscuits made of it for a large part of the time, Indians used *atta* or coarse barley flour. The British got beri-beri and no scurvy, the Indians got scurvy and no beri-beri.

Beri-beri.—This disease gave rise to 155 admissions in Kut, all in British troops. These cases were the continuation of an alarming outbreak which began at Aziziyeh (a post about

half-way between Kut and Baghdad) in October, 1915. There were besides many undeveloped or incipient cases that continued at duty. Short of producing obvious clinical beri-beri a diet deficient in special directions brings on gradually a condition of lowered stamina and vital energy and of inefficiency. This is a change to be watched for—a danger signal.

TREATMENT OF CHRONIC STARVATION.

It is essentially necessary after long periods of partial starvation to exercise the greatest caution and discretion in returning to ordinary food. Death frequently occurs in those who after forced abstinence of some duration suddenly and completely gratify the natural cravings of hunger. The whole digestive apparatus is in a weakened state, and the various glands in and around the intestines that take part in the process of digestion have undergone atrophy, and their functioning power has to be restored before they can resume work normally. The activities of the digestive organs and metabolic processes have necessarily been sluggish, and any sudden demands made upon these functions are liable to be followed by a breakdown in the machinery. The main indications in attempting to restore those in advanced starvation are—maintenance of the warmth of the body and the administration of readily assimilated warm liquid nourishment. Rest and the application of warmth (if the weather requires it) are very comforting.

When circumstances allow of it only the most digestible substances should be sparingly partaken of at short intervals—milk (which is the great standby); beef-tea, meat juices, broths, prepared farinaceous and partially digested liquid animal foods, white of egg, etc., solid food being eschewed for some days, then beginning with white fish, rice, bread, butter, and fatty food, meats, and vegetables in gradually increasing quantities, the normal amount not being administered for some months. Digestibility and nutritive capacity are the main points in the foods given. Solid food of any kind is at first quite inadmissible; any attempt made to consume ordinary solid food, no matter how urgent the cravings for it may be, is likely to be followed by serious reaction. Everyone who went through the siege of Kut required to be taken into hospital, nursed, and treated on the lines indicated above if the consequences of their chronic starvation were to be averted. Instead of that the garrison was, on capitulation, put on the coarse rations of the Turks at once, and within three weeks sent on a 1,000-mile march, much of it through an arid desert en route to various places in Asia Minor. We had published in division orders during the last week of the siege a warning as to the dangers associated with returning to normal diet after long-continued partial starvation. There being no suitable food available, and human nature being what it is, as soon as the Turks' rations were issued, especially the coarse, hard, brown rye bread and biscuits, which caused intense irritation in the stomach and intestines, a large number of British and Indian troops and followers gorged themselves with it. The immediate result was the occurrence of a violent epidemic of a disease that had all the clinical characters of cholera as already described.

During the last two months of the siege the energies of the garrison were carefully husbanded; only the most indispensable fatigues were ordered, guards and outpost duty were reduced to the lowest possible minimum compatible with the military situation, and when men began fainting on "sentry-go" at the beginning of April the two hours' spell was reduced to one hour.

It was a long time before those who went through the siege of Kut regained their normal weight; in my own case it was about one and a half years. This appears to be in accordance with the experience of all long sieges of which we have record. The digestive glands of the stomach and intestines, the pancreas, and liver, have undergone considerable atrophy, and are long in recovering their normal functional activity. It was about two years before I personally could comfortably consume a normal meal as regards quantity; earlier than that any attempt to eat the amount of food I had been accustomed to before the siege was at once followed by unpleasant effects, which, however, caused only temporary inconvenience.

I have often been asked what rations remained at the time of the surrender. On April 29th, 1916, the only food left was twenty-nine emaciated artillery horses; on that date there was not a pound of flour, *atta*, barley, or any other foodstuff available. As the Turks failed to provide any food until April 31st, the sick and wounded in hospital (about 2,500) got no rations at all on April 30th. The troops at duty marched to Shamran on April 29th, the Turks occupying Kut the same day.

CANCER OF THE BREAST.

TREATMENT OF THE PROEMIAL BREAST.*

BY

SIR G. LENTHAL CHEATLE, K.C.B., C.V.O., F.R.C.S.,
SURGEON AND LECTURER IN SURGERY, KING'S COLLEGE HOSPITAL.

[With Special Plate.]

No surgeon of experience can be satisfied with the results obtained by the present surgical treatment of cancer when it arises primarily in the breast.

The object of this paper is to direct attention to the existence of a potentially dangerous state of the breast, and to indicate the advisability of removal of a breast in this state rather than wait for the evidence of disease for which surgical measures have been proved to be so unsatisfactory. The consideration of the following facts explains why surgical measures are so often doomed to failure when primary cancer is clinically recognizable as such in the breast.

First. It is an aphorism that cancer of the breast must have developed considerably before it has attracted attention to its presence. By the time it has made itself manifest it too often has spread beyond the limit of the most extensive and skilful operation.

Second. The dilemma is really worse than this bald statement makes it appear, for the patient is usually the first to discover the indications of a tumour. Unfortunately her next step too often depends upon the relative importance she attaches to their warnings. When she regards them as relatively unimportant there will be delay in receiving the treatment which should be adopted at the earliest possible stage.

Third. While all are familiar with examples of complete surgical successes in cancer of the breast, we also know that the number of complete surgical failures is too great to justify an attitude of passive contentment with the present treatment. Moreover, the successes claimed within a few years of the operations have often proved illusive. Operative measures upon cancer of the breast have been followed by complete quiescence for ten and twelve years. Success assumed on a post-operative limit of quiescence for five years or so must be regarded as too optimistic.

Fourth. In some breasts which have been excised because they were considered to be in the proemial state I have found I was wrong and that they contained tumours. Upon careful microscopical examination of whole sections of separate breasts I discovered in them tumours of the following kinds: (1) simple papillomata, (2) papillomata the innocence of which is exceedingly doubtful, (3) malignant papillomata, and (4) one with a small cancer which was infiltrating fat outside the gland. In addition to my own patients I must refer to two others. Mr. Sampson Handley kindly sent me a breast for microscopical examination. I had seen the case clinically, and then I regarded it in the proemial state. In one of the large ducts I found a papilloma the benign nature of which is open to considerable doubt. My colleague, Mr. Burghard, who has given me great encouragement by showing his interest in my work, also kindly sent me a breast which I should have described upon clinical examination as also being in the proemial state. It was only by very careful microscopical examination of whole sections that we discovered a small cancer within the breast and infiltrating the fat outside the gland, also an apparently simple papilloma in a duct in another part of the gland. In all these patients clinical signs of tumours were absent.

Taking into consideration the whole position, it would be of great surgical importance could a line of treatment be indicated that would deal adequately with breasts in which cancer or papillomata were likely to occur, and not, as we do now, devote our attention to those breasts in which these diseases are definitely present. An absolute indication of this line of treatment would be of basic importance, and its establishment as a regular surgical procedure would be a great step in the direction of safety.

I hope to prove that there is a condition of the breast which is a prelude to those particular pathological changes to which I have alluded. I name it the "proemial breast."

I am so fully convinced that I have already begun treating breasts on this assumption. Careful microscopical examination revealed in some of them the early stages of the diseases I had hoped to be in time to prevent. I take these facts as offering remarkable evidence in my favour and supporting my belief that there is such a thing as a proemial breast.

Before I describe the characteristic features of the proemial breast it is essential to clear the ground in one important respect. It is a fallacy to maintain that every breast that appears nodular on palpation is in a pathological state. Provided there be not too great a layer of superjacent fat most adult female breasts are multinodular on palpation. The multiple nodules are mainly prominent parts of mammary ducts, and can be recognized as such by careful observation. Palpation should be continued in the normal directions of the ducts, of which the "nodule" is only a part, bearing in mind that a duct becomes smaller in calibre the nearer it is to the periphery of the gland. The examination is conducted best by supporting the pendent breast with one hand and palpating it with the fingers of the other. Also it must be borne in mind that the vascular turgescence of puberty, menstruation, and pregnancy increases the size of the glandular structures and may render them painful. It is possible that physiological turgescence may occur from other causes. Therefore I attach importance to the facts that in all such conditions the whole of the gland, and not only a part of it, would be taking part in the disturbance, and that the multiple nodules would be of the same size when corresponding parts of the same breast were compared. To make sure that the condition be physiological it is essential to examine the breast when the cause of the turgescence has passed.

Ducts are more accessible to palpation than the acini because they are more rigid in structure and towards the nipple more superficial in position.

THE PROEMIAL BREAST.

The proemial breast is worthy of due recognition in future pathological and clinical considerations for two reasons: (1) It is in a state that makes it a prelude to further pathological changes of a highly important character—mainly simple papillomata, malignant papillomata, and other forms of cancer. (2) Its clinical recognition and adequate treatment occasionally enables the surgeon to recognize (microscopically) the presence of one or more of these changes, before any clinical sign of their existence is obtainable by any other means—that is to say, when the proemial breast has merged into those profoundly important stages to which it has acted as a prelude. When once established the condition of the proemial breast is permanent. To describe next its clinical and pathological appearances, and its treatment:

Clinical.

The patient, who has generally reached the age of from 40 to 45 years, complains of pains in the breast. Occasionally it is so severe and has lasted so long that in spite of all kinds of treatment she can bear it no longer, and insists on having the breast removed. Generally the pain is not so severe and is of an aching character which is not always affected by menstruation. On questioning the patient it is found that the pain began sometimes as early as 30 years of age—more often it commenced somewhat later; also that it may have lasted some six months or one, two, three, or more years. The pain is continuous. On examination both breasts may appear multinodular. But while the nodules of the unaffected breast correspond to the signs I have described as indicating a normal breast, the nodules of the diseased breast are swollen, painful and tender on palpation, and are not of the same size in corresponding parts of the same gland. Sometimes a nodule at the periphery is bigger than one situated nearer the nipple. Careful palpation reveals the fact that the swollen nodules are mainly composed of prominent parts of tortuous ducts. The state of affairs may be limited to a segment of the breast, or two segments, one of which may be on the opposite side of the same breast, of which the intervening parts are normal. Or the whole gland may be affected by the same disturbance. There may be an intermittent or continuous discharge of serum from the nipple. A thin layer of coagulated serum may be seen on the surface of the nipple. The discharge is always small in amount.

In the later stages of this complaint the pain disappears and cysts are present in varying number. Massage, rather severe in its application, may induce a thick white discharge from the nipples and constantly from the same duct orifices.

* The term "proemial breast" is employed to indicate a condition of the breast which makes it a prelude to later developments of simple or other forms of cancer. It is precancerous, "precausory."

The fluid contains desquamated epithelial cells. It is necessary to caution surgeons not to massage the breast to elicit this information, since it must be borne in mind that it is possible that a breast diagnosed as being in the proemial state may contain a small undiagnosable cancer, and there would be risk of disseminating cancer cells under these circumstances.

Pathology.

In the early stages there is to be observed a more or less diffusely desquamative hyperplasia of the epithelium in one duct, or two or more ducts, and also in some of the acini which are in direct connexion with them. The desquamative hyperplasia is most obvious in the smaller ducts (see Fig. 1) and acini. Ducts may be affected alone and acini may also show epithelial activity where none exists in the corresponding duct. The consequence of an abnormal collection of their contents leads to distension of the ducts and acini and accounts for the immediate results of this process—namely, the formation of cysts and stagnation of their contents (see Fig. 2).^{*} Small cysts in the process of formation contain the active desquamative hyperplasia of epithelium. The large cysts are lined by a degenerated atrophied epithelium which at parts has been shed.

The connective tissue around the affected glandular elements undergoes progressive secondary change and the connective tissue cells in parts begin to multiply (see Fig. 1). Also small accumulations of lymphocytes may occur at isolated and infrequent intervals, and can be seen immediately outside some parts of the ducts and acini. In the later stages these accumulations may be more pronounced and occupy longer tracts of ducts (see Fig. 2). I repeat my belief that the proemial breasts act as menaces by being preludes to and by encouraging grave changes within them, and this contention receives support from the fact that in what I estimated and diagnosed as being only proemial breasts I also found intracystic growths of simple papillomata, of malignant papillomata, and other forms of early cancer.

Treatment.

By making particular allusion to multiple small nodules occurring in normal breasts I have at once excluded many glands that hitherto have led to misconception in many minds, and it should not lead to the assumption that both glands are in the proemial state in the same individual, although it may be so.

From what I have said concerning the proemial breast it must be concluded that I regard it with supreme importance and distrust. In saying this I do not suggest that at its best it is certainly doomed to lead to grave pathological changes, but I hold that it is in a condition which is entirely favourable for their later genesis, while, on the other hand, in alarming frequency such changes have unexpectedly been found already to be present. I look upon it and treat it in precisely the same way and for the same reasons that compel surgeons to remove an appendix that has been inflamed. The proemial breast bears exactly the same relationship to cancer and papillomata of the breast as the proemial appendix does to general peritonitis. Cancer of the breast and general peritonitis are just as far beyond surgical control now as they always have been. General peritonitis is prevented by early surgical measures. My endeavour is to bring the preventive treatment of cancer of the breast similarly into line. Preventive surgery in relation to cancer elsewhere has been adopted. Take, for instance, Sir Henry Butlin's and Sir A. Mayo-Robson's work on leucoplakia of the tongue, and the latter's work and that of Sir Berkeley Moynihan on the gall bladder and on gastric ulcer. Consciously and unconsciously surgeons are acting on the same principle when they remove early those prostatic glands which are interfering with the normal passage of urine.

My treatment of the proemial breast, in whatever stage it exists, is to remove it in the following way: I make one long curved transverse incision below the nipple, with its convexity downwards. Its length is equal to the limits of the breast; the outer end of the incision is continued into the axilla. Upper and lower flaps of skin are dissected from the limits of the breast and the axilla is opened. The nipple is reflected with the upper flap; it is not removed, care being taken to separate it from the parts immediately beneath it. In so doing it is wise to remove any white fluid that may appear at its base or from the surface from which it has been cut;

it might be infective. The breast and fascia over the pectoralis major are dissected away *en bloc*, with the lymphatic glands attached. It is essential that the removed gland should be subjected to a most careful microscopical examination for fear the breast might have passed from the proemial stage to changes of gravest issue. Should the presence of such a disaster be discovered, it is necessary then to remove the skin formerly covering the breast, pectoralis major and minor, and more complete dissection around the higher parts in relation to the axillary vein.

My hope and belief is that in the majority of proemial breasts cancer, at all events, will not be found to be present. If, however, it should be discovered, it will be a great advantage to be thus warned of the necessity of a complete operation at a much earlier date than would otherwise have been possible.

I publish the following reports of four breasts presumed by me to be in the proemial state before operation: and the microscopical appearances I found in three of them, which proved I was wrong in that presumption.

CASE I.

Female, aged 45 years, single. She is waiting for operation.

Left breast: Small gland, nipple not retracted, no discharge from nipple. In an upper and outer segment of breast there is not adherent to the skin, with defined diately above it and covering its upper scar made at an operation performed for the excision of a cyst. The rest of the gland appears normal. There are no enlarged glands in axilla.

Right breast: Small gland, nipple not retracted, no discharge from nipple. In an upper and outer segment of the breast there is a fluctuating swelling, not adherent to skin, with defined margins. Immediately surrounding it are multiple nodules which can be distinguished as swollen, tender, and painful parts of tortuous ducts. The nodules are irregular in size and larger than normal. There are no enlarged lymphatic glands in axilla.

The left breast probably contains a large cyst and possibly several small ones. The right breast is in a more serious state; the precise condition can only be revealed by careful microscopical examination of whole sections of this breast. I will report later what is discovered on that examination.

CASE II.

Female, aged 43, married, one child 8 years old, which she nursed.

Right breast: Nipple not retracted, no discharge from nipple; the gland is multinodular in all parts, most marked in segments on outer and inner areas of breast. The nodules are of irregular size, larger than normal, and are painful and tender on palpation; menstruation makes no difference to pain. The pain, which has been borne for eight months, has not been improved by rest, hot fomentations, and arm carried in sling. There were no enlarged glands in axilla.

The left breast was normal.

The right breast was removed. Fig. 3 represents the state of affairs discovered upon microscopical examination of large sections made from this breast. D is the situation of the nipple, and E E E is the direction of ducts towards it. A normal duct is to be seen at c c c. A duct, A, contains a large multiradicular papilloma, apparently benign. Another duct, B, contains the beginnings of multiradicular papillomata at three separate parts. In another part of this breast, and having no connexion with parts connected with the distribution of ducts A and B, there existed a small fibroadenoma.

CASE III.

Female, aged 58 years, married, no children.

Left breast: Nipple not retracted, no discharge from nipple. Multiple fluctuating swellings in breast of various sizes, the largest one inch in diameter. The margins of all were defined. The skin was not attached to them. She had noticed the swellings several months ago. The breast had been painful, but was not painful upon a clinical examination. There were no enlarged lymphatic glands in axilla.

The right breast appeared normal on clinical examination, and no complaints were made of it.

The left breast was removed and whole sections of the breast were cut. Many cysts were discovered of duct and acinous origins, but in a segment of its outer margin was a small cancer in the gland, and which was infiltrating the fat outside it (see Fig. 4). The whole lesion was about the size of a sixpence. In another part of the gland there was a duct containing a multiradicular papilloma.

This patient is considering whether she will take advice and have a more complete operation performed.

CASE IV.

Female, aged 42, married, two children, which she nursed.

Right breast: No retraction of nipple; no discharge from nipple. Contained in an upper and outer segment a large fluctuating swelling. Its surface was not adherent to skin; the breast was nodular throughout; some nodules were painful and irregular in size, and many were distinguishable as parts of tortuous ducts. There were no enlarged glands in axilla.

The left breast appeared normal.

The right breast was removed, and whole sections of the breast were cut for microscopical examination. I found that the

SIR G. LENTHAL CHEATLE: CANCER OF THE BREAST.

FIG. 1.—Transverse section of small duct. At five or six different parts the epithelial lining is undergoing a desquamative hyperplasia, and by this process the duct is being distended. The connective tissue cells are proliferating at *a* and at other parts. There are no lymphocytes present in this section.

FIG. 2.—Reproduction of a duct, *A*, towards its termination in branches marked *b*. The lumens of all are enlarged and full of stagnant desquamated cells. The connective tissue outside them is dense

the least distended, a fact the ducts is not due to obstruction higher up in their courses. $\times 30$.

FIG. 3.—Reproduction of part of a breast under the nipple. *D*, *E*, *E*, *E* represent the direction of ducts towards nipple. *CCCC* are parts of the same duct, which is normal. *A* is a duct which contains a multiradicular and apparently benign papilloma. *B* is another duct which is dilated, and at three separate parts there are the beginnings of multiradicular papillomata of probably benign nature. The connective tissue is dense, but otherwise there are no other pathological changes. There were no clinical signs whatever of the presence of these tumours. They were discovered microscopically in a breast I believed to be in the proemial state.

FIG. 4.—A reproduction of cancer which has infiltrated fat, into which it has spread from a small focus, clinically unrecognizable, in the margin of the mammary gland. $\times 50$.

...sides its fluid contents a large ... The epithelial cells lining the ... are columnar.

In the main parts of the tumour the epithelial cells are rigidly confined within what presumably is the cyst wall; but at isolated intervals the epithelial cells can be seen most definitely passing through the wall and invading the surrounding connective tissue. There was a blood clot in this cyst. In other parts of this breast in the neighbourhood of the tumour can be seen ducts the epithelial linings of which are in a marked state of desquamative hyperplasia, very similar to that seen in Fig. 1. Upon the condition of things being discovered by microscopic examination the patient was advised to undergo a complete operation.

The sections have been cut too recently to enable me to get them drawn for reproduction in this article. At a future date I will publish drawings made from them. The sections are at the disposal of all who care to see them.

SUTURE OF RUPTURED LEFT DOME OF DIAPHRAGM.

AT

C. JENNINGS MARSHALL, M.S., M.D., F.R.C.S.,

ASSISTANT SURGEON, KING'S COLLEGE HOSPITAL.

With Radiographic Commentary by ROBERT KNOX, M.D.,
Radiologist to the Hospital.

[WITH SPECIAL PLATE.]

A youth of 19 was admitted to hospital for injuries sustained by being thrown from his bicycle. While riding, he was thrown by a skid in front of a motor bus; he fell with the right knee undermost and then lost consciousness for a while. Unfortunately, no further details of the accident were available. At any rate, it was certain the bus passed over no part of his body. I saw the patient after attempts had been made to reduce a supposed dislocation of the knee.

There was severe shock on admission; temperature 97°, pulse rate 120, respirations 20 to 24. The right knee presented a fracture separation of the femoral epiphysis with a longish piece of diaphysis attached on the inner side. The lower end of the diaphysis presented on the outer side of the joint subjacent to the skin, which was whole. This particular displacement of fragments was probably accounted for by the manipulations.

Pain was complained of in the chest at the left costal margin about the eighth and ninth cartilages. There had been no dyspnoea, no spasm, no nausea or vomiting. The pain disappeared at the end of four days, and there was no symptom of trouble at all.

The skin showed no sign of trauma. The left chest moved but little, and was less expanded than the right. Slight cardiac pulsations were seen on the right side of the sternum; the right border of the heart was made out nearly two inches to the right of this; the left border was not determined.

Over the front of the left chest was tympany, extending up to the second rib and out to mid-axilla, where it began to yield to what became at the back slight relative dullness. Auscultation over the tympanitic area showed distant breath sounds at the upper and outer margins, none at the inner and lower part. Elsewhere the chest gave signs of partial collapse of the lung. At the left margin of the sternum there was heard at intervals a loud, intensely metallic clanking, synchronous with the heart beat. After a fortnight borborygmi were heard in the chest; they were infrequent, but had great intensity even as high as the apex of the axilla. Against the possibility of their being transmitted one noted: (1) their maximum intensity was thoracic, (2) their loudness, and (3) apparent origin very near the stethoscope. On a few occasions it was possible, by a sudden dipping of the finger-tips in the epigastrium, to cause a splash to be heard in the thorax. Diaphragmatic hernia was diagnosed on these grounds clinically.

On the fifth day the femur was plated under spinal anaesthesia. As the lower fragment offered nothing on the outer side but a very short cancellous strip, the incision was made on the inner aspect. Anatomical reposition was effected. Movement of the joint was begun a week later, and the other forms of physiotherapy added as soon as the scar permitted.

The condition of the lower limb had for this time made a proper x-ray examination of the chest impossible. The patient was screened in the supine position. The cardiac displacement was evident; the left pleural "cavity" was poorly illuminated compared with the right, and the diaphragm on that side was some one and a half inches lower. Bismuth gruel swallowed by the patient passed rapidly, to lie as a mass 3 inches by 2 inches transversely at the level of the fourth left costal cartilage.

It was thought that operative interference was indicated, though in bed the patient had no symptom, alimentary, respiratory, or cardiac. It is probable, however, that the condition of affairs on exertion might cause considerable embarrassment; further, the possibility of internal strangulation had to be borne in mind.

Intratracheal ether with the patient in the lateral position was given, the table being angled opposite the lower costal margin to give an "open out" the chest towards the operator. Five inches each of the eighth and ninth ribs were resected in the axilla. The pleura was opened at the upper part of the lower periosteal tube for its

whole length. The in-sacking of air was very slight and there was no respiratory disturbance (as, indeed, was to be expected, nearly the maximum mediastinal displacement already being present). The first structure encountered was the omentum at the greater curve of the stomach. This organ, distended to the size of a coco-nut, lay uppermost; below it was the transverse colon, and on the inner side were many coils of small intestine. The left edge of the liver just projected into the pleural cavity. The spleen was not seen.

The rent in the diaphragm began through the oesophageal opening and extended outwards and forwards for three inches, skirting the back of the trefoil. Except at the oesophageal end of the anterior limb of the tear, omentum was adherent to the edges (on the abdominal aspect chiefly). The lesser curve of the stomach appeared only at its middle, while three-fourths of the greater was seen. The cardia and the lower end of the gullet were not displaced or loosened. The gap in the diaphragm was a little over an inch at its widest; the edges were strongly resistant to a greater increase than half an inch in this direction. It seemed that strangulation was a very distinct possibility. The viscera were reduced and retained by a moist pack. At first this seemed almost impossible of accomplishment, but when the head was elevated by adjusting the table, and a supporting sandbag removed from the front of the abdomen, it became a matter of the utmost simplicity. The edges of the rent were freshened, and omental adhesions separated. Four mattress sutures were used to draw the inner edge a quarter of an inch under the outer, whose loose edge was then attached by a close row of interrupted sutures to the upper surface of the inner edge. A widely imbricated line of anastomosis was thus secured. There was but little tension to overcome in getting the edges together.

The parietes were then closed, the pressure of intratracheal insufflation being considerably increased. It was observed that the lung inflated rapidly, particularly the lower lobe, whose margin at the completion of the parietal suture extended below the line of incision and actually touched the chest wall.

Convalescence was interrupted only by bronchitis for three days. The absorption of the remaining air was gradual, H.A.B. becoming normal in six weeks.

The patient was seen again eight months afterwards. There were no symptoms of any kind. He indulges in cricket and other sport, cycles and does heavy work. The range of knee movement was 70° to 130°.

To inspect such a condition is usually to diagnose it. Symptoms offered no help, except that the complete absence from the start of dyspnoea seemed rather striking. The mechanical condition was very similar to that in pneumothorax—lung collapse, mediastinal displacement, air in the pleural cavity, albeit enclosed in bowel.

The loudness and superficial character of the rare borborygmi were nearly conclusive. The succussion splash induced by a jerk in the epigastrium may be worthy of note. The fact that the heart does not return to its place is suggestive if one has a case suspected as pneumothorax under observation for some time. A positive bismuth meal result is conclusive, as the stomach must almost inevitably be the viscus first herniated. It is conceivable that a part of the fundus might be so gripped as to prevent the entry of the bismuth. Obviously the supine position is to be adopted. The rare herniation of intestine alone—for example, colon—could be excluded or detected only by frequent examination.

With regard to the operation itself, the whole procedure was emphatically easy. While resection of ribs might have been avoided by a powerful retractor, I doubt whether the access would have been so comfortable. A longer incision would have been needed, and the window into the chest would have had ends not so wide as the middle, which here seemed a helpful feature. One thing is certain: approach from the abdomen would have been far more difficult, reduction would have been more difficult, and a deliberate imbrication of the rent could not have been done. I should like to emphasize the very striking help of posture in effecting reduction. It was noted how tough is the diaphragm—one felt satisfied that no sutures could possibly tear out.

While one did not fear any sudden change of intrathoracic tension, insufflation ether seems to be far the best for this purpose; the anaesthesia given by Dr. Richards was entirely uneventful, and at the end provided the most gratifying feature of the whole procedure—the rapidly expanding lung after its two months' collapse. The upper lobe did not expand anything like as much as the lower, possibly as this received the direct blast from the trachea.

Comments on Radiographic Appearances.

The radiograph, taken on the first visit (September 4th, 1920) to the x-ray department, shows an interesting condition on the left side of the thorax. The outline of the diaphragm is irregular and very ill defined. Above it, as high as the second intercostal space, is a translucent area which is limited in the mid-line by the spine and laterally by the ribs and intercostal spaces. Its upper margin is well defined

and apparently composed of pleura which is thickened in that region. Through this clear area the details of the ribs and scapula can be made out; there is very little evidence of detail of the lung. The lower margin is irregular and ill defined, and shows strands of denser tissue with clear areas between. The general appearance is strongly suggestive of air in the pleural cavity. It has not the typical appearance of a large pneumothorax, and is more typical of gas within a distended viscus. The nature of the appearances described was clearly indicated when an opaque meal was given to the patient and a series of radiograms composed. The whole of the meal was seen to be retained on the left side, extending from a sharply defined point at the level of the first lumbar vertebra, and extending upwards to a point at the level of the seventh dorsal vertebra. The opaque shadow, with the gas-distended space above it, occupied about two-thirds of the total thoracic space on the left side. Above the shadow of the opaque material in the viscus was a clear area, and at a still higher level a dome-shaped structure representing the limitations of the above-described air space. This structure most probably consisted of thickened pleura, and formed a limiting membrane for the herniated stomach.

The x-ray examination with the opaque food showed clearly that the stomach was situated in the thoracic cavity; the irregularity of the diaphragm and the gas formation seen in the earlier pictures are suggestive of the diagnosis, but no positive opinion could be expressed until the stomach had been filled with the opaque food. It is interesting to note that later negatives showed that limiting structure of the air space was capable of contracting to some extent upon the stomach, and this is shown by the negatives, in which the stomach is seen to contain less of the food than in those of an earlier period.

The radiograms taken on June 28th, 1921, after the patient had been operated upon, show a different appearance from those taken when he was first examined.

The upper surfaces of the diaphragm are practically on the same level. On both sides of the chest the lung detail is well seen; there is no sign of the gas, the heart now occupies a normal position, in strong contrast to the position it assumed in the first pictures, in which it was displaced well over to the right. The lungs show an increase of the root shadows, and there is evidence of enlarged glands at the roots with peribronchial thickening extending into the lung substance.

AN UNUSUAL CAUSE OF DEATH FROM CANCER.

By ERIC A. LINELL, M.D. MANCH.,

SURGICAL OFFICER, CHRISTIE HOSPITAL, MANCHESTER; SURGICAL REGISTRAR, ANCOATS HOSPITAL, MANCHESTER.

[With Special Plate.]

THE case recorded below seems to me of sufficient interest to warrant publication. The microphotographs printed in the special plate are self-explanatory, but the accompanying diagram will indicate the relations of the low-power view.

History.

E. E., female, aged 43, was admitted to the Christie Hospital, Manchester, on January 11th, 1922, suffering from an inoperable carcinoma of the larynx, which had required tracheotomy at the Manchester Royal Infirmary twelve days previously, to relieve urgent symptoms. She was comfortable until early in the morning of January 24th, when she awoke with severe pain over the precordium. At 1 p.m. she suddenly became very much worse, and was reported as almost pulseless. After the administration of camphor, ether and brandy hypodermically, and of mustard leaves over the precordium she was somewhat relieved.

Examination.

The patient was very pale and obviously dying. The pulse was almost imperceptible and the heart sounds were very weak, but there was no dilatation of the organ and no bruits could be heard. There were moist sounds at the base of the left lung. These were the only ante-mortem findings of note except for slight sepsis round the tracheotomy tube. The diagnosis seemed to lie between cardiac embolus and an acute mediastinitis. The patient died at 2 a.m. the next day, January 25th.

Post-mortem Examination (3.30 p.m., January 25th, 1922).

The tissues around the tracheotomy wound were infiltrated with the primary carcinomatous growth. On opening the chest there was found a left-sided pleurisy with a small amount of fluid and some collapse of the lung. An abscess of this lung was seen

to have burst into the pleural cavity. Nodular secondary growths were found on the pericardium and the left pleura, and there were deposits in the bronchial glands.

The heart was of normal size, firmer than normal, and on opening the cavities ante-mortem clot was found in all but the left ventricle. The clot was particularly firm in the right auricle, and on removing it a papillomatous mass the size of a pea was found projecting into the cavity from the smooth endothelial wall. There was no indication of this mass on the outer aspect of the auricle, and it seemed to be arising immediately under the endocardium.

Histological examination of this growth shows the typical structure of squamous-celled carcinoma (see high power microphotograph). From the facts that it is infiltrating the subendothelial heart muscle and is separating the muscle fibres (as seen in the low-power microphotograph) it would appear that the embolus had arrived via the blood or lymphatic system, and that it was not an implant on the auricular endothelium from embolism down the superior vena cava.

The position of the tumour is of interest, and by promoting thrombosis in this cavity it accounts, in my opinion, for the fatal termination of the disease within twenty-four hours of the onset of acute symptoms.

My thanks are due to Dr. Charles Powell White for his histological investigation of the case and for allowing me to prepare the microphotographs from one of his sections.

SOME NOTES ON ORAL SEPSIS IN ITS RELATION TO GENERAL DISEASE.*

BY

J. M. ACKLAND, M.R.C.S. ENG.,

DENTAL SURGEON TO THE ROYAL DEVON AND EXETER HOSPITAL
CONSULTING SURGEON, EXETER DENTAL HOSPITAL.

[With Special Plate.]

SINCE the year 1900, when Dr. William Hunter first wrote in regard to oral sepsis and its connexion more particularly with anaemia, increasing attention has been given to it as a factor in many other diseases. Sir Thomas Barlow at that time made reference to its importance. The practical result was the recognition of oral sepsis as the greatest septic infection in medicine, and oral antisepsis as one of the most important, simplest, and easiest means for the prevention of groups of maladies affecting almost every system of the body.

It has been said that the alveolar process—with the exception of the intestines—is the largest and the most frequently diseased part of the body from which toxins are liable to be absorbed. A very small amount of toxin absorbed from the alveolar process will do more harm than a large amount absorbed from the intestinal tract, as the toxins are carried direct into the circulation, and not—as in the latter case—through the portal vein into the liver.

Oral sepsis is a comprehensive term, and includes pyorrhoea, alveolar abscess, and the pathological conditions existing at the root of a dead tooth. With regard to pyorrhoea we have to remember that it could not occur without streptococci and staphylococci. It is the penetrating activity of the streptococcus which creates the bleeding lesion, thus opening the way for the staphylococcus, which dissolves the tissue and creates the pocket. Probably the most common of the ill effects of oral sepsis is a state of malaise, in which the patient complains of tiredness, slackness, lassitude, and a general though indefinite feeling of unfitness. We may get functional cardiac effects, such as palpitation, or a state of nervous debility and depression.

Oral Sepsis and Disorders of the Heart.

In speaking of its effect upon the heart, in addition to the functional disturbances associated with indefinite malaise

* Read at a meeting of the South-Western Branch of the British Medical Association.

due to oral sepsis, the difficulty may be to decide how much of the lassitude is due to a relative degree of cardiac inadequacy, or whether both things are not due to septic absorption. In some of these cases the palpitation is most distressing, partaking more of a true tachycardia.

Ulcerative endocarditis, both acute and chronic, has been traced to this disease, and in many cases has been known to follow the extraction of septic teeth, where local anaesthetics have unfortunately been used. And here, perhaps, I may be allowed to sound a note of warning, especially in those cases where the symptoms are acute, against many extractions at a time. We have to remember that each extraction gives a greatly increased surface for absorption of toxins, and it is well to allow these cavities to at any rate partially heal before further extractions are attempted. It is a good plan to pass a probe into the sockets for the first few days, and syringe well with warmed antiseptics, using a syringe with a bent nozzle, and getting the cavities well cleared out, especially in the lower jaw, where the drainage is bad. In addition, the patient should rise several times a day, especially after every meal. For this purpose I have found peroxide very useful.

This treatment cannot be too rigorously followed. In a recent *Journal of the American Medical Association* several cases are cited in which an organic affection of the heart was made worse by extractions of teeth, due entirely to lack of drainage in the affected area, the tooth socket being filled with a firm clot of blood and septic absorption following. The reckless use of vaccines, whilst neglecting this elementary principle of drainage, is greatly to be deprecated.

Oral Sepsis a Cause of Neuritis, Chronic Rheumatism, and Arthritis.

Probably the most common of all the groups of diseases arising from oral sepsis is that of neuritis, chronic rheumatism, and arthritis, and the attacks of acute gout in pre-disposed patients is certainly influenced by this disease.

Dr. Beddard, in the *Transactions of the Medical Society of London*, places up less than 90 per cent. of the cases of so-called rheumatoid arthritis in this category, and in this he is supported by Sir William Willcox. In many cases the lesions in the mouth are apparent at once, but in many others it is not so, and the cause of arthritis and allied conditions is often deeply seated near the apex of the tooth, with no local symptoms of pain, swelling, or tenderness, and here the x rays come to our aid. Photographs—kindly done for me by Mr. Muir, radiologist at the Royal Devon and Exeter Hospital, reproduced to illustrate this paper—show the osteitis and destruction of alveolus; also a clear space indicating the presence of an apical abscess. In these spaces will be found pus and granulations infected with pathogenic streptococci, and from them virulent toxins—if not bacteria—are carried into the blood stream. Sir William Willcox quotes a case under his care where an abscess of this kind was the undoubted cause of malignant endocarditis—an identical organism being found in the blood stream and dental abscess.

In cases of arthritis having a dental origin streptococci showing similar bacteriological characters may nearly always be found in the faeces. As Sir Thomas Horder points out, there are certain diseases more often associated with the sepsis connected with dead teeth than with a suppurating periodontitis. These diseases are specially those leading to chronic inflammation of fibrous tissues and serous membranes. Various kinds of so-called rheumatism come into this category, as well as certain cases of neuritis, and especially the more chronic and progressive cases of multiple arthritis that follow oral sepsis. The type of streptococcus found in these cases is not the long-chained *Streptococcus pyogenes*—that is, the streptococcus of acute suppurations—but *Streptococcus salivarius*, a variety of short-chained streptococci, held up at the very root of the dead tooth and sometimes ensconced in fibrous sacs adherent to the crooked fang; and the pathological process going on at the root of a dead tooth—leading to sclerosis of the tissues here—is precisely similar to that which is taking place in the joint structures, the muscular fasciae, and the sheaths of the nerve trunks. In these cases quite often there is no suppurations at all, and it is a great error to jump to the conclusion that because there is no suppurations there is no infection. We must remember that this micro-organism at the roots of the teeth is in close contact with the blood stream, whereas we may have considerable suppurating surfaces, as in pyorrhoea, where there

is a free exit for the toxin—and it is here that the x ray proves of such value, though even this is not infallible as an index of pathological conditions. In these cases Sir William Willcox says vaccine treatment is of great value, but strongly insists that it must be accompanied by removal of the causal infection. Affected teeth should be removed, and a vaccine prepared after, guarding against possible contamination. Vaccine treatment is usually required for three months at least, with weekly and later fortnightly doses. Here I would mention one short case of my own.

H. S., male, aged 65, consulted me in July, 1921, with neuritis in his right arm of four months' duration; he had tried electricity, massage, and various drugs without relief, and still carried his arm in a sling. I found four teeth the sockets of which were affected with pyorrhoea and one dead tooth. These were extracted under ether, and his recovery was rapid and complete—so rapid, indeed, that I feared a relapse. I wrote the patient a fortnight since—that is, after nine months—to inquire as to his condition. He replied that he could use his arm almost at once, play golf and tennis daily, and had not had a twinge since.

Oral Sepsis in Phthisis and Anaemia.

Oral sepsis undoubtedly plays an important part in many cases of pulmonary tuberculosis. The effect of the removal of the teeth is to increase for a time the amount of toxins absorbed into the circulation, and this has the effect of decreasing the local resistance of the lung tissue, with the result that the disease becomes worse. In cases, therefore, where the disease is active, the radical treatment of the oral sepsis should be delayed until a quiescent stage and then carried out very gradually.

Again, we have the relationship between chronic lymphadenitis and oral sepsis, and the possibility of serious general infection breaking through the lymphatic barriers, already lowered in resisting power by the repeated attacks of the commoner products of oral bacteria.

The next disease I would touch upon is anaemia and its association with oral sepsis. Dr. William Hunter, in a paper published recently, says that two forms of severe anaemia are to be recognized: the one the great haemolytic disease, idiopathic or pernicious anaemia; the other a non-haemolytic or septic anaemia, and the cause in no less than nine-tenths of cases is oral sepsis—pyorrhoea. In other cases it is overlooked sepsis in the antrum and nasal sinuses, but the pathology of the two kinds is different in that the septic anaemia is non-haemolytic and owes its character to deficient blood formation, just as the haemolytic or pernicious or glossitic anaemia owes its character to excessive blood destruction. This septic anaemia may exist alone, but it far more frequently complicates other anaemias in which similar conditions of oral sepsis are present; and herein lies part of the great importance of oral sepsis in the disease called pernicious anaemia, but which Dr. Hunter prefers to call "glossitic," sore tongue being one of its earliest and chief diagnostic features, and in this way we get rid of an ill-omened prognostic name. Gastro-intestinal disorders are not infrequently due to septic conditions in the mouth; these are associated with inability—from the defective and painful condition of the teeth—to masticate properly, and are the cause of loss of weight in patients suffering from these conditions. Here I may mention two cases, the first a typical one:

S. R., male, aged 30, thin, emaciated, pasty appearance, complained of a general feeling of malaise and listlessness, with considerable loss of weight; his mouth was full of septic stumps and pyorrhoea. On my advice he came into a nursing home, and there, under a general anaesthetic—a few teeth at a time—I gradually cleared his mouth. There was a marked improvement after each operation: the patient's colour improved, he began to put on weight, without teeth at all, and, as he said, he felt a different man.

The other case is that of a patient in North Devon. B. L., male, aged 40, in the last stage of phthisis, suddenly began to bring up all his food; he could retain nothing; all treatment seemed to be of no avail. I was asked to go and see him, and found a month full of pyorrhoea, some teeth extremely loose, and their sockets oozing with septic matter. After much consideration, for the patient was in a very weak condition, it was decided to advise extraction of five of the very loose teeth. The position was explained to the relatives, who gave their consent. The next morning I went down again, accompanied by Mr. Henry Andrew as anaesthetist, removed the loose teeth, syringed the sockets, and cleansed the mouth with peroxide. From that day everything was kept down, and although the patient only lived some six or eight weeks, I think it would probably have been a matter of a very short time if his mouth had not been dealt with.

Both these cases were officers invalided home from Mesopotamia, and I think I am right in saying they had suffered from trench fever.

Influence on Traumatic Lesions.

The influence of oral sepsis on traumatic lesions must not be forgotten. As an example, a young man injures his knee at football. The mischief does not yield to treatment, and a chronic synovitis is established. Removal of dental sepsis is followed by complete recovery.

Oral sepsis may penetrate the orifices of the parotid and submaxillary glands, and set up a chronic inflammation in the ducts and substance of the glands. Acute septic infection, which used to be common in the parotid and was often fatal, has become rare, because one of the duties of the nurse attending exhausted medical and surgical patients is to keep the mouth as clean as possible. There are other and fortunately rare cases due to pyorrhoea. One was reported in the *Lancet* a short time since. The patient had a perfect cesspool in the upper jaw from pyorrhoea, ulceration of adjacent cheek, a spreading cellulitis, which led the way to the cavernous sinus; the left crus cerebri was involved, with a corresponding right-sided hemiplegia. Death ensued in twelve hours from profound septicæmic coma six days after the onset of symptoms.

No patient who has been under treatment for Vincent's angina should be discharged as cured until swabs from around the teeth are negative and free from the fusiform bacillus regarded as the cause of Vincent's angina.

Chronic nasopharyngitis, septic bronchitis, skin troubles, middle-ear disease, are some of the other diseases which may be due to or influenced by oral sepsis.

Oral Sepsis in Children.

I am sure we all recognize the serious effect of oral sepsis in children. Their physical and often their mental growth is retarded. A common result in children is gastro-intestinal disorder, as evidenced by gastric and abdominal pain, diarrhoea of an offensive character, with much undigested food in the motions, sleeplessness, loss of appetite, marked wasting, and pallor. Many of the septic teeth are tender, with the result that we get imperfect mastication, and this, combined with the sepsis, produces the trouble. Night sweats are often present; tuberculosis is suspected, slight albuminuria may be found, and nephritis sometimes intervenes.

Dr. Still lays particular stress on oral sepsis due to dental disease, which he says is so common in children, and enlarged glands in the neck are also common; but it must be remembered that pharyngeal conditions, adenoid hypertrophy, and tonsillar enlargement have much to answer for. Tubercle bacilli have been demonstrated in diseased teeth; but even if it could be proved that these never make their way directly from a diseased or septic tooth it would still be almost certain that this disease in children is indirectly responsible in no small number of cases for the tuberculous infection of glands. Indeed, in the child of tuberculous family it is a powerful predisposing cause of tuberculous infection perhaps down the whole cervical chain.

The failure of an infant to gain weight is frequently associated with oral sepsis in a nursing mother, and the removal of the septic teeth has been followed by a rapid improvement in the weight of the child. Many of the children vomit the milk after being fed. This points to its containing some toxin which the gastric mucosa will not tolerate.

An interesting case—quoted recently—is that of a child suffering from diarrhoea which failed to yield to treatment. The mother was found to have a very septic mouth, and as she persisted in kissing the child they were separated for a while, the result being that the intestinal trouble cleared up forthwith.

Even from this brief survey it is clear that oral sepsis may affect the organism in different ways—indeed, may influence the course of most diseases; and Dr. Stanley Colyer sums up the position thus:

"The somewhat bizarre nature of the effects that have been attributed to dental sepsis may at first sight make the relationship appear improbable, but when once the principles that underlie the subject have been grasped it will be realized that the conclusions are a necessary outcome. In all diseases there are two factors at least—the seed and the soil—without which disease cannot exist. The seed varies, the soil varies; never are the two the same, never is the relation repeated. This is why variation in disease is common, and in no two persons does it run a precisely similar course. Dental sepsis is but a comprehensive term to include various septic conditions in the mouth—it is not a disease. The germs causing the sepsis vary, and so the germs passing into the body and the toxin absorbed produce different results in different people. It cannot be said why germs of a particular kind entering

one body produce a septicaemia and in another an infective endocarditis, or why a toxin in one will produce an anaemia and in another a neuritis; but that such is the case seems almost certain, and for the time being we must rest content with the fact."

The tendency in medicine in the present day seems to be to divide disease into two classes—those due to germ infection, and those not due to this cause; and if, in any case coming within one category, we inquire whether there is a source of infection and test the results of treatment directed to its removal, we may arrive at a conclusion of practical value.

We cannot expect to cure all our cases, even by the most drastic treatment, but we must not argue from the particular to the general in cases of failure. There may be other foci of infection: an intestinal tract may be permanently infected; or, as in some of the most chronic cases, the damage may be beyond repair. Time will not permit of my saying more on this far-reaching subject. If I have succeeded in a very small way in calling attention to its importance my end is attained.

Since the foregoing notes were written an article has appeared in the *Lancet* (April 1st) which, while giving oral sepsis its due in playing an undoubtedly important part in the causation of general disease, points out the great need there is for more conclusive pathological proof than is often forthcoming in support of the clinical evidence available.

As giving some account of the extreme divergence of opinions naturally springing from the present state of insufficient pathological authority on this subject, and at the same time presenting a dispassionate view of the extreme schools of thought, this article is most interesting and suggestive. Professor Martin Fisher of America—a well-known writer on infections of the mouth—puts forward dental infection as a cause of very many conditions; whereas Professor Hugo Schottmüller of Hamburg, whilst conceding that oral sepsis, like infection elsewhere, is capable of affecting the general health, does not believe that it acts as a direct cause of general disease. As the writer goes on to point out, dental infections may often be so situated that there is no large outpouring of bacteria into the circulation, yet there is a possibility of small doses of bacteria escaping from time to time and altering the bodily resistance. It is quite certain that no one is in a position to deny that oral sepsis constitutes a potentially and often an actually dangerous condition, and anyone with experience amongst hospital patients especially cannot fail to be struck by the appalling prevalence of oral sepsis. The result of treatment is in very many cases followed by a cure of some other trouble or disease due to it. Whilst every case must benefit generally from its treatment, the great thing to which we should direct our energies is to make pathological proof more convincing. When this has been achieved I am sanguine enough to believe that very great and more certain results will follow the judicious treatment of oral sepsis.

THE SOLUBILITY OF QUININE HYDROCHLORIDE.

BY

J. HAMILTON CRAWFORD, M.B., M.R.C.P.E.

(Department of Pharmacology, University of Edinburgh).

The quinine salt most generally used formerly was the sulphate, but more recently the hydrochloride has come into favour as being much more soluble in water. The sulphate is taken up only by 725 parts of water, while the hydrochloride is dissolved by 35 parts. Each is readily dissolved with acid, the bisulphate in 9 parts and the acid hydrochloride in 0.6 part of water. The presence of excess of acid is a disadvantage in intramuscular or intravenous injection, and here especially the solubility of the neutral hydrochloride weighs heavily in its favour. In the intravenous injection especially the hydrochloride is likely to be injected, not in distilled water but in saline solution or in Ringer's solution, and it is therefore of importance to ascertain whether its solubility is affected by the constituents of these fluids. The saline solution used was 0.85 per cent. NaCl. The Ringer's solution was made up to contain NaCl 0.85 per cent., KCl 0.03 per cent., CaCl₂ 0.02 per cent., and NaHCO₃ 0.02 per cent.

Distilled water dissolved 1 part neutral hydrochloride in	35 parts
Saline solution " " " "	103 "
Ringer's solution " " " "	110 "

The lessened solubility in the presence of NaCl is, of course, only an example of the law, well known in physical

chemistry, that two salts with a common ion lessen each other's solubility, but I had not appreciated that this would hold for the low concentration of NaCl in these solutions. The still lower solubility in Ringer's solution is due to its slight alkalinity, which may lead to the precipitation of the base, and also to the fact that it contains a slightly greater number of chloride ions.

It was found that on making up the solution with saline which had been kept for a month the solubility was the same as with fresh saline, but that with Ringer's solution the solubility became less in proportion to the age of the Ringer's solution—that is, with Ringer's solution which had been standing for a month and a half, the solubility was 1 in 135. Also if the solution of quinine hydrochloride in Ringer's solution is allowed to stand for one week it is found that quinine is precipitated, only 1 part in 125 remaining dissolved.

These results show that it is advisable to use freshly prepared solutions for intravenous injection. By heat quinine hydrochloride can be dissolved in saline or Ringer's solution to the same extent as in distilled water, but there is a tendency for adposit of crystals to take place in the needle as the solution becomes cooled during injection.

Relative Acidity of Acid Quinine Hydrochloride and Quinine and Urea Hydrochloride.

The hydrochloride of quinine and urea has been introduced of late years and may be regarded as a substitute for the acid hydrochloride. As regards solubility, each is soluble in less than its own weight of water. It is of importance to find whether quinine and urea hydrochloride differs from the acid hydrochloride in acidity. I have made up solutions containing the same amount of quinine per cent.; 1.33 per cent. solution of quinine and urea hydrochloride contains the same amount of quinine as a 1 per cent. solution of acid hydrochloride. On titrating these solutions with N/10 NaOH, using phenol red as indicator, I found that

5 c.cm. quinine and urea hydrochloride solution = 1.4 c.cm. N/10 NaOH.
5 c.cm. acid quinine hydrochloride solution = 1.3 c.cm. N/10 NaOH.

The pH of these solutions was then tested, using standard pH solutions with methyl orange as indicator. It was found that pH of quinine and urea hydrochloride was 3.5 and the pH of acid quinine hydrochloride was 3.7.

It is seen that the acidity of these two drugs, both as shown by the hydrogen ion concentration and the titrable acidity, is practically the same. Thus quinine and urea hydrochloride appears to possess no advantage over acid quinine hydrochloride.

MEDICAL, SURGICAL, OBSTETRICAL.

FUNCTIONAL AMBLYOPIA.

DURING the last two years I have had under my observation ten scholars with defective vision in whom there was no error of refraction and no discoverable disease to account for the bad vision. The children, when in school, were found to have defective vision and in consequence were sent for treatment.

The sexes were equally divided. Their ages ranged from 9 to 13 years, and their visual acuity, as tested with Snellen's distant types, from 6/18 to 3/60. Both eyes were alike, or nearly so. The refractive conditions, estimated under atropine, showed practically no error, or only slight degrees of hypermetropia or astigmatism. The media and fundi were normal. On placing a -2 D. sph. over an eye the vision was usually made worse, but on adding to this a +2 D. sph., the one lens neutralizing the other, the child immediately read right down to 6/9 or 6/6. This manoeuvre was equally successful in all the cases.

These striking results were due to suggestion, or to withdrawal of psychic inhibition. In one case the fields of vision were tested with a small white object and were found to be contracted down to about 20 degrees. Some could read the test types for near vision, at least for a short time, while their distant vision was very imperfect. All were encouraged to believe that they could read the distant types, and most of them did so intimately, in a slow, hesitating manner. Swanzy wrote of the "fluctuating vision" in these cases, a condition that we often observe.

All these children were dull and listless, some ready to

weep, and others decidedly anaemic. Probably these conditions of lowered vitality were partly due to the present industrial depression with consequent unemployment and underfeeding.

Some years ago I reported¹ the case of a girl who recovered her sight after having been for two years in an institution for the blind; her eyes presented no evidence of disease.

JAMES ALEXANDER WILSON, O.B.E., M.D.
Cambuslang, Glasgow.

RUPTURE OF VARICOSE VEINS MIMICKING ACCIDENTAL HAEMORRHAGE.

A PRIMIPARA, hourly expecting her confinement, on getting up into bed bled profusely. A midwife was summoned and she sent for me. I found the patient perturbed but otherwise looking well. The bleeding had stopped and her pulse was slow. I was told that there were no pains and no signs per vaginam of dilatation of the cervix and no boggy feeling through the fornices.

The possibility of accidental haemorrhage was entertained and a sedative was given. Two days later labour came on and the first stage was without any haemorrhagic abnormality—thus ruling out placenta praevia. The second stage was delayed, so I put on forceps. The case being primiparous I was surprised to find the anterior vaginal wall bulging down in front of the advancing head. I pushed back this protrusion, and as I did so—gently—I felt my finger perforate the tissues, and I wondered why the anterior vaginal wall should be so fragile. When the head was born there was a gush of blood from the vagina, so I promptly delivered the shoulders; luckily the child was small. There was no tear of the perineum. The blood now poured from the vagina, so I pressed the soft tissues against the symphysis, with happy results, for there was no more bleeding.

Inquiry next day elicited the history of the patient, during her pregnancy, having been examined by a doctor, who told her she had varicose veins on the front wall of her front passage, and that trouble during her confinement might result. She moved out of this doctor's area and forgot to mention to me what she had been told. This varicosity had not been seen by myself or the midwife, as we had only inspected the parts when the patient was recumbent, and she had not thought it worth while to mention this varicosity.

Had the patient presented the signs and symptoms of severe loss of blood when I saw her first I might have packed her vagina as recommended for accidental haemorrhage by the late Dr. Berry Hart in his book, *Guide to Midwifery*, 1912: "This treatment applies to cases where the cervix is undilated and the uterus not acting" (p. 514).

The above case is a good example of the disadvantage to doctor and to patient of the usual plan of the doctor being booked and then not seeing his patient till the child is born or some complication arises.

Dr. Berry Hart in his book says: "Of course the medical attendant should have seen his patient on several occasions before" being called to her in labour; but how many prospective fathers are prepared to meet this expense?

Kilnberst, nr. Rotherham. CHARLES J. HILL AITKEN, M.D.

KNOT IN UMBILICAL CORD AS A CAUSE OF ACCIDENTAL HAEMORRHAGE.

The following case may be rare enough to warrant publication:

Mrs. S., aged 24, second pregnancy, noticed haemorrhage at 6.30 a.m. on May 7th. She did not expect her confinement for another two weeks. When I saw her at 10.30 a.m. she was considerably collapsed, and still having contractions, though not severe, haemorrhage. The uterus was not unduly large and the os admitted two fingers, and was painless. It was a vertex presentation, and there was no sign of placenta praevia. There were no "pains," and no foetal heart sounds were audible.

An enema, followed by rectal saline, decreased the haemorrhage but failed to produce uterine contractions, as also did 12 c.cm. of pituitrin. As at 2.30 p.m. there were still no contractions, I packed the vagina tightly, and this produced the desired effect, as the child was born (dead) at 5.30 p.m. A large clot of blood followed, and immediately afterwards the placenta. The cord, which was longer than average, had a single complete knot in it, and the great circulation had apparently become completely shut off, causing separation of the placenta and haemorrhage before labour set in.

The patient had complained of great foetal activity for some days previously.

Reports of Societies.

NOTIFICATION OF TUBERCULOSIS.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, held on May 26th, with the President, Dr. A. K. CHALMERS, in the chair, Dr. REGINALD DUDFIELD read a paper on "Reforms needed in the notification of tuberculosis."

Dr. Dudfield began by remarking that the primary object of notification was to secure that all tuberculous patients should have the advantage of treatment under the scheme. A second, and by no means unimportant, aim was the collection of statistical data. Without reliable data as to the prevalence of the disease it was impossible either to make adequate provision for treatment or to judge the results either of treatment or methods of prevention. At present notification was incomplete. During the eight years 1914-21 1,439 deaths from all forms of tuberculosis occurred in Paddington. Of these 298 represented cases only made known to the speaker by the registration of death, while in 106 instances notification was made after death—that is, in 404, 28 per cent., of all cases ending fatally, the first information of the presence of the disease was the death certificate. Turning to notifications, of 3,723 cases notified during 1914-21, 106 referred to persons already dead and 247 to persons dying within a month of notification, so that 353, 9.8 per cent., could not be dealt with under the tuberculosis scheme. The full significance of deaths occurring within a short time of notification could only be known were the normal duration of a case of tuberculosis known. The speaker held that most cases of pulmonary tuberculosis in the adult were reactivations of infections acquired in infancy or youth and that accordingly some proportion of deaths occurring shortly after notification must be inevitable. Dr. Dudfield referred to the work of Wurtzen of Copenhagen on the average duration of pulmonary tuberculosis reckoned from the onset of symptoms. The averages (in months) varied from 19.5 in the age group 15-20 to 45.8 at ages over 45 in males, and from 21.2 to 47.4 in females. Dr. Dudfield then considered the distribution of fatal cases not notified to him.

Deaths Occurring in Paddington.—These numbered 143 from all forms of tuberculosis during the eight years considered; 87 of these were under the care of practitioners.

Deaths Occurring outside Paddington.—There were 155 such deaths, a large majority in institutions. Of 92 deaths from pulmonary tuberculosis in institutions, 60 occurred in lunatic asylums. Dr. Dudfield found that the practice of the medical staff of institutions as to notification was not uniform; some did not notify, others refrained from doing so at the request of the medical officers of health of the districts in which the institutions were situated, others notified systematically to the local medical officers of health, but the certificates were not transferred to Dr. Dudfield. It was to be remarked that the late Local Government Board had informed the superintendent of one of the large asylums that "where . . . a patient has been for a long time an inmate of an asylum the Board are advised that the asylum should be regarded as the usual place of residence" of the patient for the purpose of the regulations. The result was that while the death when it occurred was allocated by the Registrar-General to the area whence the deceased was admitted to the asylum, no transfer of the notification certificate to the medical officer of health of the district of origin was made.

Of 106 notifications received after the death of the patient—62 with respect to cases of pulmonary and 44 with respect to other forms of tuberculosis—54.8 per cent. of the former and 75 per cent. of the latter were deaths in institutions. Of 247 cases wherein death occurred within a month of notification, 68.4 per cent. were in institutions.

Dr. Dudfield presented tabulations of the distribution by age and sex of cases notified 0-1, 1-3, 3-6, and six or more months before death. The conclusion reached was that cases fatal within six months of notification were not a random sample. Without laying too much stress upon the matter, he was inclined to think that patients whose cases terminated fatally within six months of notification were, on the whole, younger than those who survived six months.

Dr. Dudfield, having pointed out that in 1919-21 the percentage of fatal cases only heard of at death was greater than in 1914-18, passed to a consideration of the changes of

incidence and fatality, using index numbers in terms of the records of 1914 as a base. He thought the figures afforded some evidence that work under the scheme had been useful, but, in his opinion, the administrative side of the scheme should be tightened up, and to that end notification should be improved. Article V of the existing regulations ran:

Subject to the provisions of the Regulations every Medical Practitioner (unless acting as a School Medical Inspector) attending on or called in to visit any person (whether at an institution or otherwise) shall, within forty-eight hours after first becoming aware that such person is suffering from tuberculosis, make and sign a notification of the case in Form A, and shall transmit the notification to the Medical Officer of Health for the District within which the place of residence is situated at the date of notification;

Provided that a Medical Practitioner shall not notify a case of Tuberculosis under this Article if he has reasonable grounds for believing that the case has already been notified . . . to the Medical Officer of Health for the district within which the place of residence of the person is situate;

Provided further that if a notification is required in pursuance of this Article in respect of an in-patient at an Institution the notification shall be sent to the Medical Officer of Health for the District in which the usual place of residence of the patient is situate.

Dr. Dudfield thought that the first of the two provisos should be repealed, and an addition made to the first paragraph requiring the medical practitioner to repeat his notification should the patient move into a new district and the practitioner continue in attendance. Regarding the second proviso, Dr. Dudfield thought that the certificate of notification should be sent to the medical officer of health of the district in which the institution was situated. Dr. Dudfield also thought that "suspect" cases should be notified, the more so as institutional treatment was now available for "suspect" cases for observation.

With regard to Article VII, providing for notification by medical officers of Poor Law institutions or sanatoriums of cases admitted and not required to be notified under Article V, and also of discharges other than transfers; Dr. Dudfield thought the provisions should apply to all institutions and to "suspects." He also thought that when the case was first notified on Form C, the medical officer of the institution should be required to supply the name and address of the practitioner arranging for the admission of the patient, if the medical officer of health desired the information. When a patient was admitted from one district and discharged to another, the medical officers of health of both districts should be notified. As at present drawn the article required the admission to be notified on Form C, even after "transfer," but not the transfer-discharge on Form D, so that there was an incomplete record of institutional treatment and an excess of recorded admissions over discharges and deaths. Dr. Dudfield thought that opportunity of immediate treatment was lost by a refusal of some practitioners to notify until the tubercle bacillus had been demonstrated in the sputum. Lastly, he referred to the difficulty of preparing accurate statistics of prevalence and secular change. The first source of error was the possibility of cases recorded as "primary" in one area being really "secondary" to notifications in another area. The second source of error was due to failure to trace removals. The latter might be dealt with by altering the form of certificate, requiring the practitioner to state that he had made inquiry as to previous notification, or by arranging for the district medical officers to forward to the county medical officer a list of cases where there has been removal to an untraced destination.

COMPARATIVE UROLOGY.

The programme arranged for the Section of Urology of the Royal Society of Medicine for its meeting on May 25th was one that dealt entirely with the comparative aspect of medicine and pathology. Professor Hobday contributed a paper on "Calculi in animals," and it had been arranged that Mr. Kenneth Walker should follow with a discussion of "The comparative anatomy and the physiology of the accessory sexual glands."

Professor HOBDAY, in opening his paper, expressed his thanks to the Royal Society of Medicine for having asked him to read a paper, and said that veterinary surgeons appreciated the efforts made by the Section of Urology to draw together the kindred sciences of human and animal surgery. He was convinced that much good would result from closer collaboration, for after all the problems with which the veterinary and the human surgeons had to deal

were essentially the same. It was true that a veterinary surgeon worked under certain disadvantages, and possibly also certain advantages. For one thing he had to rely entirely on signs, as his patient could give him no history and make no verbal complaints. At the same time his patient could tell him no lies. Calculi were common in domesticated animals, especially in dogs and horses. The passage of a calculus along the urethra of a dog was complicated by the presence of a bone in the penis. In the case of the bull a similar complication was provided by the fact that the penis was S-shaped. This generally necessitated surgical intervention in the way of urethrotomy. Professor Gardner had analysed a large series of calculi obtained from animals, and had found that the commonest ingredient was calcium carbonate. Oxalate and phosphatic calculi were less common. An interesting point was the legal aspect of calculus. A lawsuit had recently taken place because a veterinary surgeon passed a valuable dog as fit and the dog had to submit to an operation for calculus some three months later. Professor Hobday concluded by showing a series of skiagrams of calculi in dogs and some illustrations of the operative technique of lithotomy in animals.

The President of the Section, Sir THOMAS HORDER, in thanking Professor Hobday for his paper, said that he considered it an admirable step that practitioners in veterinary and human surgery should meet together to discuss their problems, and he hoped that much good would result thereby.

Sir JOHN BLANN-SUTTON said that he felt that perhaps the chief danger of such a paper was that those urologists who had heard it might arrive at the conclusion that they themselves were capable of dealing in future with any complaints from which their own pet animals might suffer. He would deplore such an event, and personally would not entrust his own cat to anybody except Professor Hobday. During his long connexion with the Zoological Gardens he had performed post-mortem examinations on some thousands of animals, and it was interesting to know that calculi were of the extreme rarity amongst wild animals. In only two cases had he discovered them—once in a sloth and once in a bear. He had only one question to ask. Professor Hobday had spoken of the commonness of multiple calcium carbonate calculi in dogs. Had the possibility of a parasite providing the nucleus for such calculi been considered?

Sir JOHN THOMSON WALKER said that he felt with Sir John Blann-Sutton that it would be a great help if urologists could keep in touch with veterinary surgeons in order to work out such a problem as the etiology of calculus. The rarity of uric acid and oxalate calculi amongst animals was an interesting fact. He would like to know the state of the urinary tract in those animals in which calculi were discovered. Was obstruction present, and had any peculiarity in feeding an influence on the presence of calculi?

Mr. RALPH THOMPSON could not agree that calcium carbonate calculi were uncommon in man. He also believed that oxalate calculi were not so common as was generally supposed. The legal aspect of calculi interested him, and he suggested that after all a period of three months was sufficient to permit of the formation of a calculus in a dog.

Mr. FRANK KIDD disagreed with Mr. Thompson's remarks about the commonness of calcium carbonate calculi in man, and thought that the results of Professor Gardner's analyses of animal calculi were of considerable interest. He would like to know whether it was customary to close suprapubic wounds or drain them.

Mr. SWIFT JONES remarked that it had always been a great surprise to him that those animals, such as birds and lizards, who passed urine so thick with uric acid crystals that it was semi-solid, should suffer so little from stone. He would have thought that they would have shown a great tendency to the formation of calculi, but such was not the case. Had Professor Hobday any figures showing the relative commonness of renal calculus amongst cattle and horses? He himself had wondered whether the entirely different construction of the kidneys in these two animals might not influence the formation of calculi.

Professor WOODBRIDGE, speaking as a veterinary surgeon, expressed his appreciation of the hospitality that the Section of Urology had extended to him. He answered some of the questions that previous speakers had submitted, and said that the question of a parasite providing the nucleus for calculi in dogs had been thoroughly explored. It had, however, been found that dogs, at any rate in this country, suffered very

little from urinary parasites, and no trace of such had been found in the centre of calculi.

Professor HORDER then replied briefly to the questions put to him by previous speakers. Owing to the lateness of the hour it was decided that Mr. Kenneth Walker's paper on "The comparative anatomy and physiology of the accessory sexual glands" should be postponed until the next meeting of the Section. Many interesting exhibits were on view, Professor Hobday showing a collection of calculi removed from various domestic animals, and Mr. Kenneth Walker specimens of the prostate of the badger, the wombat, and the dog.

LOCALIZATION OF TOXI-INFECTION LESIONS IN THE CENTRAL NERVOUS SYSTEM.

At a meeting of the Manchester Pathological Society on Wednesday, May 10th, with the President, Mr. J. HOWSON RAY, in the chair, Dr. DAVID ORR and Dr. A. CORSEAR STURROCK read a paper entitled "The influence of disturbance of the sympathetic mechanism on the localization of toxi-infective lesions in the central nervous system."

They stated that lymphogenous toxi-infections of the central nervous system followed definite nerve root paths and were primarily systemic. Non-systemic lesions such as those of pernicious anaemia, Addison's disease, and cancer cachexia were the result of blood-borne infection, but to call them haematogenous did not adequately explain their distribution. Degenerative changes in the non-systemic lesions or combined scleroses in the cord were found over the surface of the white columns and around the postero-median septum, which parts derived their blood supply from the pia-arachnoid, whilst the grey matter and most of the basis bundles, which were supplied from the anterior spinal artery, escaped. The stress of these lesions fell on those segments of the cord from which white sympathetic rami passed. In the brain the same distribution was found, lesions in a general blood infection being found in parts supplied by pia-arachnoid.

Experimental work was carried out on rabbits. First, a study was made of vascular changes in the brain after division of the cervical sympathetic, and secondly of vascular and nervous elements in the brain in similar animals after flooding the circulation with an emulsion of *B. dysenteriae* Shiga injected into the vein of the auricle. The results might be summarized as follows:

Lesions due to sympathetic division alone. These were vascular dilatation, perivascular oedema, slight proliferation of adventitial cells which might be a response to increased permeability of the vessel wall resulting from sympathetic paresis and the release of certain noxious products from the circulation. There was at the same time some morbid change in nerve cells, and the areas affected were those supplied by pial vessels—namely, the cortex cerebri and the cornu ammonis, the fascia dentata, the amygdaloid and caudate nuclei, which were supplied by folia of pia carrying vessels invaginated from the surface of the brain.

When, after division of the cervical sympathetic, a general intoxication was produced, lesions were found affecting the same areas, but to a much greater degree, and the unilateral sympathetic division intensified the morbid lesion on the same side. The areas involved in both series of experiments were the archaic regions of the brain plus the cerebral cortex, which was developed from the rhinophallium. All were supplied by pial vessels and under sympathetic control. It would appear, therefore, that the sympathetic nervous system played an important part in toxi-infective inflammation and degeneration and its involvement was a contributory factor in the localization of lesions, not only in the central nervous system, but probably wherever they might occur. Further investigation on this point might lead to a better comprehension of the genesis of obscure non-systemic lesions affecting both spinal cord and brain.

While lesions were found in all the areas mentioned above, the most striking and remarkable was extensive periarteritis in the head of the caudate nucleus just external to the anterior horn of the lateral ventricle. This lesion was so well defined and so localized as to seem of special significance in view of the obscurity which at present surrounded the etiology of certain lesions which implicated the lenticular area.

In these experiments on acute intoxications ependymal cells of the lateral and third ventricles and of the iter, as well as the epithelium of the choroid plexus, were in a state of active

secretion. This secretion consisted of small globules of a translucent and highly refractile material, which coalesced into larger masses, consisting of an inner core with a weak affinity for certain stains and an outer marginal zone with a marked affinity. This was an active secretory process of a lipid material, which was probably of the greatest importance as an active defensive measure against intoxication as well as one destined for the purposes of regeneration and repair.

These lesions, occurring in the archaic part of the brain and intensified by disturbance of the sympathetic mechanism as well as in the superficial layers of the cortex cerebri, might play an important part in the genesis of disturbed emotional states. They were produced through interference with the blood supply without added toxin, but were greatly increased by the additional factor of an experimental intoxication. This fact inclined the authors to take a much broader view of the genesis of emotional disturbance, and tended to take the question out of the purely psychical field of argument. In emotional disturbance the initial stimulus might come from the sensorial cortical areas, the peripheral sensory nerves of the life of relation, or through the endoerino-sympathetic system, which subverted the function of kinaesthesia and was the physiological foundation for those feelings of well or ill being so important in the psychic and physical life of the organism. These kinaesthetic or vegetative stimuli, when normal, remained subconscious, but leapt into prominence so soon as they became abnormal. Every stimulus which impinged on the central nervous system produced results which embraced a vast territory, and whether the exciting stimulus be central or peripheral its influence reverberated throughout the whole nervous system and its appendages, and was certain to find its expression in a reaction on the part of the psychic and vegetative life.

A healthy affective tone played no small part in keeping the higher cortical and intellectual functions up to their highest level, and affective tone and emotion were influenced or often greatly disturbed by morbid changes in the archaic portions of the brain. It was there and in the cerebral cortex that lesions occurred after interference with the cervical sympathetic in the rabbit, and as affective tone and emotion were so closely linked up with the function of the endoerino-sympathetic system their disorder was probably the result of a psycho-physical process which altered the nutrition of the ganglion cells which governed their mechanism. A similar process was no doubt accountable for the large group of functional disturbances termed the "psycho-neuroses." Future researches might ascribe more importance to the effects of altered nutrition of the central nervous system than to the purely psychic element, though one recognized the influence of the one upon the other.

Benign Epithelioma of Skin.

Dr. LOUIS SAVATARD reminded his hearers that rather more than thirty years ago Brooke had first described before this society small tumours of the skin, to which he had given the name of "epithelioma adenoides cysticum," and that Brooke's original paper appeared in the only published *Transactions of the society* (1891-92). Fordyce of New York was at that time carrying out similar research, and communicated his results to the sixteenth annual meeting of the American Dermatological Association in September, 1892. Brooke and Fordyce's clinical and histological observations were almost identical, and to their masterly descriptions there was to-day little to add. Last summer the speaker had by chance come across one of Brooke's original cases, and he showed slides of the condition then and now. He stated that in their multiple variety there was little difficulty in diagnosis, and that the uniformity of the lesions readily differentiated them from multiple rodent ulcers. When solitary lesions presented themselves—and he had had five examples—the clinical diagnosis from a non-pigmented naevus was not possible. When these solitary lesions became ulcerated, as they had in three cases, they simulated early rodent ulcers or early epitheliomas. Some of the lesions showed pigment beneath the epidermis, in the adenoid masses and fibrous stroma. Many of the cases presented other naevi associated with the tumours. The communication was illustrated by numerous lantern slides.

A MEETING of the West Kent Medico-Chirurgical Society was held in the Miller General Hospital, Greenwich, on May 12th. Dr. C. T. T. COMBER, O.B.E., occupied the chair, and delivered his presidential address, in which he gave an account of the early days of his practice on the Yorkshire

moors. He described the collection of plants and putting them up to dry in the doctor's surgery. There was much superstition, and he saw a "holy stick" to which was attributed miraculous powers of healing. He described an operation on a countryman on a farm, where the patient held the candle whilst the surgeon amputated the leg. He showed an original stethoscope, wooden pill boxes, an early tonsillotomy, and an instrument for extracting teeth with a T-shaped handle. A smoking concert was afterwards enjoyed by a large company of ladies and gentlemen.

Reviews.

A MOORLAND PRACTICE.

THE late Dr. R. W. S. BISHOP's book, entitled *My Moorland Patients*,¹ contains no small store of wisdom entertainingly surrounded by anecdotes of his medical experiences in his Yorkshire practice. The work has been edited by a friend, who also furnishes a biographical note from which we learn that this "Yorkshire Doctor" was born at Ripon, studied at Leeds and London, qualified in 1889, spent some time in Paris (where he gained an easy fluency with the language), returned to England, where he acted as an assistant in Derbyshire, and finally practised for some twelve years at Kirkby Malzeard, on the moors north of Ripon, in or near Richmondshire. He retired from practice and settled in Tanfield on the river Ure; in 1915 he was attacked by a painful disease, from which he ultimately died on December 31st, 1921. His book was written in the intervals of acute suffering, and in its cheery optimism and constant good humour shows well how a brave man faced for himself the King of Terrors, whom he had so often held at bay for others amongst his moorland patients.

Dr. Bishop has in this book done for the people of the north-west part of Yorkshire something of the same kind that Turner did for Richmondshire's hills and valleys; he has pictured them in all their moods, and has shown them in storm and sunshine, in the sterner phases of tragedy, and in the lighter aspects of native humour. In one chapter some moorland tragedies are described with graphic pen, and another gives specimens of Yorkshire wit and humour; but all through the thirteen chapters an appreciation of the humorous in life runs cheerily like the moorland beck of the frontispiece. Indeed, one can easily understand that without an eye for such a way of looking at the discomforts (to use no stronger word) of medical practice in the North Riding the moorland doctor's life would be hard beyond bearing. After recounting the many things a man has to give up in these solitudes, Dr. Bishop sums up with a clear note of affection for the moorlands: "It was God's own country... the pages of the great book of Nature were always invitingly open, and there were ample opportunities for sport of every kind. The people, on the whole, were most kind and hospitable. Their folk-lore, habits, and language were a source of perpetual interest and study, and, if the conditions were trying, it was a healthy land."

A distinct peculiarity of country practice is early pointed out in the reflection that the patients are, unlike those in the towns, more or less stationary, and that therefore the doctor gets to know their individual character and ways better. One morning Dr. Bishop was rather worried: he had just seen two women living next door to each other; one he could not persuade to go to bed, the other he could not persuade to get out of bed. Individual eccentricities all become accentuated, and curiosity is everywhere rampant. Smoke from an unusual chimney was enough to set tongues wagging. "Another chimney smoking at Trotter's this morn." "What's up? Onnyways t' bairn isn't looked for yet awhile. Must be his sister fra Lunnon, or yon painting chap is there agean." There is a sombre side to things too: the frequent intermarrying of cousins is held to have something to do with the frequency of insanity; excellent teeth, too, are becoming rare.

Dr. Bishop had many exciting experiences. Snowstorms brought him into danger, as on the day when he took a short cut and unknowingly skirted a precipice by a margin of eight inches. The farmer whom he had acquainted with his intention had merely said, "Ye mun tak care, Doctor"; but he had later gone out after him with a stable lantern. He

¹ *My Moorland Patients*. By a Yorkshire Doctor (the late Dr. R. W. S. Bishop). With illustrations. London: John Murray. 1922. (Pp. xi+212. Price 12s. net.)

had adventures with unfriendly dogs and with "saucy" bulls. A medical friend of his was once, after much preparation, on the point of plunging a knife deep into a painful carbuncle when the patient remarked, "If I give mouth t'and dog'll click yo for sure," pointing to the sheepdog under the table suspiciously watching proceedings. It was not easy to get another doctor to help in operative work, for the relatives were sceptical about the necessity and still more about the speed called for. "It's none a gallopin' matter?" asked a husband, very loath to start; some time afterwards Dr. Bishop found him laboriously shaving, and was told, "I never go to Muxley without shaving; it's none a gallopin' matter, is it?" There were, of course, many obstetric occurrences, and these appear under the euphemism of "waiting for the hatching of a moorland chick." The hospitality following such events was oppressive. In addition to "wotting the baby's head" there was much solid food to be eaten; on one occasion the doctor was to be seen running at top speed with a black bag at 3 o'clock in the morning to escape from fried Yorkshire ham and a pursuing recently made father. Such hospitality must generally be accepted if one is not to be called "igh, 'aughty, and pompy."

There is an exceedingly interesting chapter on old Yorkshire words, which, especially in connexion with medicine, are not lacking in force and expressiveness. The grave prognosis and the approach of death are deftly described as "making bad mends," "ganning t' wrang road," "sweealing away," "tapering off," and "pegging out." After death comes the "pinkers," which is the name given to the women who lay out the body; both Dr. Bishop and his editor are puzzled about the derivation of this word, but it may be suggested that as "pinkin' in of the day" sometimes means the hour of twilight, so the term may have been applied to the women whose duties brought them to the person who had just passed into the night of death.

One might easily go on quoting from this fascinating record of moorland practice; but one more story must suffice. Dr. Bishop once put his thermometer in the armpit of a sick farmer, and went away forgetting to remove it; on his return he expected to find it smashed; he got a welcome, however, from the old man, and the precious instrument quite whole, with the following explanation and comment: "Ah's glad to see thee, I can tell thee, had what a job I've had wi' yer fanglement. It kept slippin' doon an' I puts it back, an' it slipped ageean, an' I puts it back ageean. By gum I nobb't winked (slept) a bit afore it slipt ageean. I towed all t' nect wi' it, but it's deean me ner hurt (much good), an' I sall soon be makin' good mends."

INTERNAL SECRETIONS.

PROFESSOR SWALE VINCENT has published a second edition of his book on *Internal Secretion and the Ductless Glands*.² The first edition, published in 1912, was exhausted in 1914, and the appearance of the new edition has been delayed in order to allow time to give adequate expression to the changes brought about by the researches of recent years. The author has exerted that rigid criticism and wise scepticism which are required in dealing with a subject which has become the happy hunting ground for intra-professional quackery, and for that exploitation of the practitioner and his patients carried on by the drug makers. The bibliography has been omitted in this edition, because when brought up to date it was very long and because the papers since 1917 are abstracted in *Endocrinology*, and since 1915 in *Physiological Abstracts*. The amount of space given to clinical subjects has been increased considerably. Many of the new illustrations are photographs of patients suffering from diseases of the organs of internal secretion.

As examples of the value of this important work to the practitioner we may cite the following extracts from the chapter on the pancreas: "Whatever may be subsequently discovered to be the true function of the islets of Langerhans, their intimate anatomical relationship with the zymogenous tubules, the numerous transition forms in all groups of vertebrates, and the transformation of alveolus into islet, and vice versa, all appear to prove conclusively that the islets are not organs *sui generis*, but an integral part of the pancreatic tissue." Again: "Recently it has been found that diabetes may be induced artificially in the dog if a sufficient portion of

the pancreas be removed, leaving the remainder with its normal blood supply and its normal connexion with the duct. In such cases the progress of the disease is hastened by carbohydrate feeding." "Organotherapy—treatment of diabetes with pancreas or extracts made from it—appears to be useless. The most modern form of treatment and, so far as can be judged from the clinical evidence available, the most successful form, is by fasting, combined with vigorous exercise." "An important function of the pancreas appears to be to increase the resistance of the body towards bacterial infection. Extracts of pancreas are employed medicinally in gangrene and tuberculosis, as well as in pancreatic diabetes. The use of such extracts with the object of increasing the resistance to infection is of recent date, but is deserving of further practical study." Be it noted that the Toronto physiologists have just discovered how to make an extract of pancreas potent against diabetes.

Turning to the chapter on the reproductive organs we are reminded that in the human subject Lichtenstern reports that after loss of both testes, transplantation of a testis from another man restores the previous physical and psychical condition. An excellent, restrained, and cautious summary of the probable functions of the adrenals is given on page 248.

The view put forward by the author that the coeliac bodies are safety valves in the course of the peripheral circulation seems very questionable; safety valves to what—blood pressure? After summarizing the reported effects of extirpation on the pituitary, experiments of Camus and Ronssy are cited on page 365 "which, if confirmed, will necessitate a reconsideration of our whole attitude in relation to the pituitary body."

COLLOIDAL CHEMISTRY OF THE PROTEINS.

THE researches of W. PAULI on the proteins with reference to colloidal behaviour have had an important share in the development of our present knowledge of colloids, and have added considerably to our information on the properties of the protein molecule. The appearance of a book from the pen of this investigator is therefore of sufficient interest to attract the notice of all who study chemistry in its relation to biology. His book, which has been already translated into English by P. C. L. THORNE, under the title *Colloidal Chemistry of the Proteins*,³ is not a complete handbook on the subject, but is intended to give a connected account of the author's investigations, and of the theoretical conclusions developed from them. The reader is presumed to possess a certain acquaintance with the characteristics of colloids such as may be acquired from reading an introductory work, as, for example, that of E. HATSCHEK, recently published, to whom acknowledgement for helpful advice is expressed in the translator's preface to the English edition. The methods employed by the author are described, and the results achieved by him are presented in their relation to those of other workers with the aim of connecting and co-ordinating the theoretical views which are supported by his experimental work. The methods principally employed were those which are designated "electrometric" and "electrophoretic." They were used to determine to what extent salt formation takes place, under varying conditions, between proteins and those acids and bases which are capable of combining with proteins. The degree of hydrolytic dissociation and of ionization of the salts formed is illustrated by the results of extensive investigations. No unusual demand is made on the reader's knowledge of physical chemistry in order to follow the results of experiment and the theoretical discussions; they are approached from starting points familiar to all, and are presented in terms that are clear and free from the ambiguities which frequently attend a translation. We must not omit to note that ample data are given which may be valuable to those whose interest is more directly practical.

COMPARATIVE EMBRYOLOGY.

LIKE almost every other branch of science, that of the comparative embryology of vertebrates has made enormous advances within recent times. The magnitude of the subject may be realized by a glance at Professor BRACHER's new *Traité d'embryologie des vertébrés*.⁴ It contains 600 pages and

² *Colloidal Chemistry of the Proteins*. By Professor Dr. W. Pauli, translated by P. C. L. Thorne, M.A. Cantab., A.I.C. Part I. London: J. and A. Churchill. 1922. (Demy 8vo, pp. xi + 140; 27 figures. 8s. 6d. net.)

⁴ *Traité d'embryologie des vertébrés*. Par A. Bracher, Professeur à l'Université de Bruxelles. Paris: Masson et Cie. 1921. (Roy. 8vo, pp. xv + 691; 567 figures.)

¹ *Internal Secretion and the Ductless Glands*. By Swale Vincent. LL.D., M.R.C.S., L.R.C.P., F.R.S. Edin., F.R.S. Canada, F.Z.S. Second edition. London: Edward Arnold. 1922. (Demy 8vo, pp. xx + 422; 105 figures. 25s. net.)

nearly as many figures, and provides a voluminous and most useful bibliography brought well up to date. Most earlier textbooks have dealt very largely, if not exclusively, with the embryology of mammals. Though such books serve a useful purpose, they fail often to give that comprehensive survey of the subject so necessary in order to grasp the true evolutionary conception to be derived from a comparative study of ontogeny. Professor Brachet's volume fulfils this object in an excellent manner.

The scheme adopted is to give an account of the development of the different systems as they occur in the different classes of vertebrates, having previously devoted the earlier chapters to a general account of the origin and development of the sexual cells and of the foetal membranes.

The author, while adopting the idea of development from three centres of growth which he terms acrogenesis, cephalogenesis, and notogenesis, appears to realize the difficulty of its application to such a form as the acraniate amphioxus. He brushes this difficulty aside, perhaps somewhat lightly, by stating that amphioxus is a very simplified vertebrate, and is only of use in the early stages of development—namely, segmentation, gastrulation, and the formation of the germ layers. In other words, amphioxus does not fit in with the theory.

In discussing the theory of the germ layers, which the author regards as fundamentally true, he states that it must not be pushed to the extremes some authors have attempted in the past. For example, he points out that the sphincter muscle of the iris has been shown to be of epiblastic origin; the same can be said of the muscles of the sweat glands in the skin and of the galactophorous canals of the mammary gland. From a consideration of these and other facts, Professor Brachet is led to suggest that the germ layers, like the blastomeres, "out non potentialité réelle et non potentialité totale"; by the former he means what they normally become, by the latter what they are capable of becoming under varying influences, natural or experimental.

The interesting and much-debated question of the segmentation of the skull is discussed in the light of the varying results obtained by different investigators, more particularly with reference to the selachians. The conclusion reached is that the number of trunk segments incorporated in the formation of the head varies not only according to different groups, but even according to the species.

Enough has been said to show that Professor Brachet's book is not a mere statement of embryological details, but that the more important theoretical aspects of the subject receive attention. The book is a valuable one and will be welcomed by all embryologists; and, as every such book dealing with so intricate a subject should be, the illustrations are numerous and exceedingly well executed. That so much can be devoted to illustration is a hopeful sign that indeed "things are looking up" amongst some of our allies.

NOTES ON BOOKS.

THE popularity of Dr. W. A. BREND'S *Handbook of Medical Jurisprudence and Toxicology*⁵ can be gauged from the fact that the fourth edition follows the third within the space of three years. Of this small work we may say again that it furnishes an excellent outline of forensic medicine and toxicology for the use of students and practitioners, and that the information given, so far as we have tested it, is not too much condensed for a clear understanding of principles. The new edition contains the same number of pages as its predecessor, and in other respects the alterations are few. We observe that in Chapter XVII, on medical privileges and obligations, some paragraphs have been modified in accordance with recent changes in the law or in administrative procedure. On the other hand, in the section on cocaine poisoning the sale and prescription of this drug is said to be still subject to regulations made under the Defence of the Realm Act; the regulations now in force were made under the Dangerous Drugs Act, 1920. Fashions in textbooks come and go, but we foresee a long period of usefulness for this very short but none the less readable and trustworthy guide to the medico-legal aspects of practice.

Dr. ALEX. MAXWELL ADAMS, of Tibshelf, Derbyshire, has published an interesting little book⁶ on the medical history of his own branch of the Adams family. The author gives

⁵ *A Handbook of Medical Jurisprudence and Toxicology*. For the Use of Students and Practitioners. By W. A. Brend, M.A.Camb., M.D., B.Sc.Lond., of the Inner Temple, Barrister-at-Law. Fourth edition, revised. London: C. Griffin and Co., Ltd. 1922. (Pott 8vo, pp. xiii + 317, 10s. 6d.)

⁶ *A Dynasty of Doctors*. By Dr. Alex. Maxwell Adams. Reprinted from *The Hamilton Advertiser and County of Lanark News*. 1922. (Pp. 64.)

particulars of sixteen of his family who were, or are, members of the medical profession, and he informs us further that all the living members of the family are, or have been, members of the British Medical Association. Perhaps the most interesting chapter in this history is that devoted to the life of Alexander Maxwell Adams (*primus*), the first of the many distinguished medical men of his line, who was born in 1792 and died in 1860. He was a friend of Dr. Robert Knox, the anatomist who was more or less innocently implicated in the Burko and Hare murders, in regard to whom the author gives some hitherto unpublished anecdotes. Scattered throughout the other chapters of the book are many other stories, new and old, of medical men and medical life. The author in his own career has had a varied experience of the world, from town and country practice in Scotland to the tea gardens in Assam, then West Africa, round Cape Horn in a sailing ship, an insurrection in Chilo, and eventually seventeen years in rural Derbyshire. Of the present generation of the Adams family detailed here, perhaps the most distinguished is Dr. James A. Adams of Glasgow, consulting surgeon to the Glasgow Royal Infirmary, and the well-known member of the General Medical Council. Dr. A. M. Adams is to be congratulated on his record of a notable medical family.

The Practitioner's Loose-Leaf Pocket Book,⁷ brought out by Messrs. H. K. Lewis and Co., is a nicely got up and convenient arrangement whereby case records, visiting lists, temperature charts, and records for vaccination and infectious diseases, all on thin cards of the same size, can be carried about in a case, from which they can readily be removed. The loose-leaf system has been employed with success in various publications, and in this instance its application to a visiting list is most convenient, for it enables it to be used in connexion with a card-index catalogue, and the number of loose-leaf cards can, of course, be varied to suit individual requirements.

THE STORY OF "BRAIN."

COMPLIMENTARY DINNER TO DR. HEAD.

A COMPLIMENTARY dinner was given to Dr. Henry Head, F.R.S., on May 26th in recognition of his eminent services to neurology as editor of *Brain* for seventeen years. Most appropriately, remembering the fundamental importance of his own contributions to neurology, Sir CHARLES SHERRINGTON, President of the Royal Society, was in the chair.

The CHAIRMAN, in proposing the health of Dr. Henry Head, said that under his direction the influence of *Brain* had been increased and extended. It formed a living bond between neurologists in these islands, across the Channel, and beyond the Atlantic. Every worker in neurology, wherever his lot was cast, had learnt that if he took thorough work to the editor of that journal he was sure of a sympathetic hearing and of an opportunity. Dr. Head had consistently upheld the scientific method in neurology, both in his own work and in the selection of papers for publication; he had his reward in the position *Brain* had attained as a worthy representative of British science and a moving spirit in the development of neurology throughout the world.

Sir DAVID FERRIER, at the invitation of the Chairman, sketched the history of *Brain*. In 1877 some of those most interested in neurology felt that the time was ripe for the establishment of a special journal. The reports of the West Riding Asylum, the first school of neurology in this country and founded by Sir James Crichton-Browne in 1871, had come to an end in 1876, when their editor was appointed Lord Chancellor's Visitor in Lunacy. Under the editorship of Groom Robertson, then Professor of Psychology in University College, London, *Mind* had been started in 1876, but it was concerned mainly with pure psychology, and a journal more particularly devoted to the anatomy, physiology, and pathology of the nervous system seemed to be needed. A committee, consisting of Sir James Crichton-Browne, Sir John Bucknill, Dr. Hughlings Jackson, and himself, resolved to establish such a journal, and selected the title *Brain*—a title which was warmly approved by Charcot, among others. It was to be managed by the committee, and edited in alternate years by Crichton-Browne and Ferrier. The first number was issued in April, 1878, and this rather unusual, and to the committee rather expensive, arrangement, as to the editing continued for five years. Then with Volume VIII Dr. de Waverille became acting editor, working under the Editorial Committee, to which Dr. James Ross of Manchester and subsequently Dr. T. Buzzard were added.

In 1888 *Brain* became, with Volume X, the journal of the newly founded Neurological Society, but retained its title and editor. When Dr. de Watterville retired and went to live in Switzerland Dr. Percy Smith succeeded him, and was remarkably successful in relieving the financial difficulties under which *Brain* had always laboured. When he handed over to Dr. Head, in 1905, the journal was free from debt, and the high scientific reputation it had from the first enjoyed had since then been not only maintained but greatly enhanced, both by what may truly be termed the epoch-making studies in neurology by Dr. Head himself and by the many valuable papers which he had secured to the journal from contributors both at home and abroad. English neurologists had good reason to be proud of the position which *Brain* occupied in the world of neurology. Dr. Head's resignation of the editorship was a great loss, but they had the consolation of knowing that his mantle had fallen on one who would prove himself well worthy to wear it—Dr. Gordon Holmes.

Dr. HENRY HEAD, in responding, said that *Brain*, after its foundation in 1878, had a severe struggle for life and suffered from a constant deficit, which was defrayed from the pockets of the editors. It was while Dr. de Watterville was editor that *Brain*, in 1888, became the organ of the Neurological Society, and its position from that time forward ought to have been secured. Unfortunately, although the published papers grew in value expenses also increased out of due proportion. When Dr. Percy Smith took over the editorship of the journal it was saddled with a large debt, and there were no assets but the annual subscriptions from the Neurological Society, which were insufficient to meet current expenses. By rigid economy and the strictest attention to finance Dr. Percy Smith succeeded in producing a condition of solvency. "I am delighted," Dr. Head continued, "to see him here to-night, for had it not been for his devotion there would have been no journal to-day. When I took it over from his hands it was free from debt, but there is no security in this mutable world, and within two years we were faced with the amalgamation of the Neurological Society into the corporate body of the Royal Society of Medicine. This was in 1907; it meant the cessation of all obligatory contributions, and *Brain* was thrown on to the world to sink or swim on its own merits. Guarantors came forward; the form of the journal was changed so as to improve the character of the page, a new font of type was cast, and each volume was issued at 14s., which was then considered a fair price. Subscriptions flowed in to make up the deficit due to the loss of members of the Neurological Society, and I am proud to say that the guarantors have never been called upon to contribute a penny. The next crisis came with the outbreak of war; in 1915 contributions ceased; I was almost in despair. But during the early days of the war I had been reading Dr. Hughlings Jackson's papers on aphasia, and was so struck with the way in which they had been lost to science that I reissued them as a double number of the journal. I received letters from all parts of the world about them, and v. Monakow not only translated them into French but devoted a large issue of the *Schweizer Archiv* to a critical consideration of Jackson's views, which were entirely unknown on the Continent. Then Sir Charles Sherrington came forward with his classic paper on "Postural activity of muscle and nerve," which has had so profound an influence on English neurology, and we were saved. The issue of the journal might be delayed, but every year of the war a volume appeared and the character of the papers retained a high standard. Then suddenly we woke up to the danger produced by the colossal rise in the price of paper and the treble increase in wages. In 1916 we were a paying concern, but in 1917 with the same number of pages we were in debt. Drastic measures were taken and we pulled through. Finally, by the end of the last financial year (June, 1921), we had paid off our debt without touching capital and were again making a profit. Moreover our subscribers had increased, in spite of the rise in the subscription to 24s. a volume. Through all of these changes and chances, I have had the unvarying support of the committee of guarantors, and I cannot find words adequate to express to them my thanks. A united country can present a firm front to adversity and is able to make itself felt in the comity of nations. This we have done. For *Brain* has become an international organ of neurology. It is universally taken to represent the serious side of English work. To be truly international it is necessary to be at the same time national. The Continent wants no pale reflection of itself. English neurology has influenced foreign thought because it has brought into knowledge something distinctive.

It has been characterized throughout by two features—its dependence on clinical observation and its consistency in looking at pathological facts from the physiological point of view. There is no doubt that this began in 1859, when Brown-Séquard was appointed to the National Hospital, Queen Square. Hughlings Jackson—tended by that adventurous genius, more course with his famous Victor Bazire to Brown-Séquard himself. The next most serious influence to which English neurology has been exposed was the publication in 1906 by their Chairman of the "Integrative action of the nervous system." This reinforced the tendency, always present, to regard pathological facts from a physiological standpoint, a principle still incompletely assimilated by our colleagues abroad. Thus, with every number of *Brain* issued from the press it becomes more and more obvious that we have a message for the world. We can hold up our heads and speak with the enemy in the gate. It is our business, therefore, to raise our journal to the highest pitch of efficiency as the expression of English neurology. This is the task for the younger men, and I rejoice to think that it has passed into the competent hands of Dr. Gordon Holmes. As an old captain I can take my leave with a certainty that the ship will make voyages into fresh lands and carry fruitful cargoes to the greater glory of that branch of science we all have so truly at heart.

The health of the chairman was proposed by Sir WALTER FLETCHER and briefly acknowledged by Sir CHARLES SHERRINGTON. The guests, who numbered between forty and fifty, took opportunity after the dinner informally to thank Dr. James Taylor, who made the arrangements.

A HALF-CENTURY OF PUBLIC HEALTH IN NORTH AMERICA.

BY

JOHN C. McVAIL, M.D., LL.D.

(Continued from page 153)

III.

FOOD CONTROL.

THROUGHOUT the Jubilee volume a reader in this country will often be struck by the legislative and administrative difficulties which arise from the fact that each of the States in the great republic is in many ways practically independent of the rest, and that the functions of the Federal Government in respect of control and co-ordination are limited. This is well illustrated in the article on Federal food control by Dr. Carl L. Alsberg, Director of the Food Research Institute of the Leland Stanford University.

A model law was prepared, but Federal control was thought unattainable. State action was sometimes limited to special objects, such as the protection of the dairy industry from competition by substitutes. In 1881, through the influence of a joint committee representative of various public bodies, a food and drug law was passed for the State of New York, which it was hoped would be generally adopted by the several States. Various other States passed food laws within a few years, but uniformity only began to appear with the passage of a Federal Food and Drugs Act in 1906. This Act was supplementary to the laws of the separate States; not only did the laws differ from each other in terms, but the interpretation put on them differed also, so that what was permitted in one State was prohibited in another. Under the Federal Act a considerable degree of uniformity was achieved through the operations of an office of co-operation established by Dr. Alsberg. The Secretary of Agriculture is at the head of the system and acts through the Bureau of Chemistry. There are stations in the leading trade centres. With regard to the general effect of the Act Dr. Alsberg makes the following statement:

"Through the drastic power conferred in the seizure action of the Federal law, it is possible by means of concerted action of Federal, State, and municipal officials, to seize in widely separated parts of the United States a large number of shipments of any manufacturer who may be found to be shipping in interstate commerce foods and drugs adulterated or misbranded within the terms of the Federal law. . . . The usual effect is an immediate change for the better in the product. . . . Probably no commodities regularly sold are to-day as free from adulteration and misbranding as are foods."

Newer and refined forms of adulteration are being developed with the idea of cheapening the product, and though these

are not directly hurtful to health, yet effective control requires professional men of high training. Dr. Alsberg urges that such men cannot be obtained without adequate salaries, that there is more work to be done in establishing food standards, and that education should go hand in hand with regulation and legislation.

In an article on food conservation Professor Samuel C. Prescott of the Massachusetts Institute of Technology shows how the food supply of the world has been in effect increased by the invention and development of methods of preserving foods which, when fresh, have only a very localized area of availability. Dehydration, canning, and refrigeration are the methods discussed and described.

Dehydration, which is the oldest method, was resorted to, though not always successfully, for preservation of vegetables during the American civil war, also for Alaska during the Klondike boom, and again in the Boer war and the world war. If the process is properly applied to materials in prime condition they can be restored by soaking in water. The question whether vitamins are adversely affected by dehydration is not yet settled.

A method of canning was patented so early as 1810, but it was Pasteur's discoveries that made a scientific system possible. The difficulties overcome up to and including the modern application of steam under pressure are recounted. The industry now includes the preservation of nearly all classes of food—soups, fish, shellfish, meats of all kinds, sausage, baked beans, vegetables single and combined, cereals, poultry, milk, butter, cheese, syrups, fruits, and many others. Though refrigeration is of ancient origin, sound frozen meat was first successfully carried to England from the United States in 1875-76, and from Australia in a refrigerator ship in 1880. Professor Prescott holds that but for conservation "food prices would be prohibitive, the health of urban communities would be endangered, and starvation would be imminent in our large cities."

MILK CONTROL.

The importance of milk control seems, if possible, to be even more fully appreciated in America than in this country, owing perhaps to the higher summer temperature. Excepting that little or nothing is said either as to details of the construction, ventilation, and cleanliness of cow-houses, or fraudulent adulteration by addition of water or abstraction of fat, no aspect of the question appears to be omitted from the paper Dr. Charles E. North has contributed. It is pointed out that Dr. W. M. Taylor of Penrith was the first to call attention, in 1857, to the conveyance of typhoid fever by milk, and the first (ten years later) to trace the spread of scarlet fever to a milk source. Dr. North calls attention to an important event in 1881—the publication by Mr. Ernest Hart, then editor of the *BRITISH MEDICAL JOURNAL*, of a list of epidemics due to milk: 50 of typhoid fever, 15 of scarlet fever, and 4 of diphtheria. The earliest reported outbreaks of diphtheria due to milk were by Dr. Jacob at Sutton in 1877 and Mr. W. H. Power in London in 1878. In the same year the first recorded outbreak of septic sore throat due to milk was reported, 300 cases having occurred in connexion with one dairy at Aberdeen, as well as 90 among boys at Rugby School.

In America a great diminution of epidemics due to milk has taken place since 1907. Until then pasteurization was practised by few cities, but it has become very general. Dr. North gives a table, on the lines of Mr. Ernest Hart's, of milk epidemics gathered from many sources in America and elsewhere, year by year from 1857 to 1920. These statistics certainly show a very remarkable diminution after 1907, maintained up to and including 1920, when the table ends. For the thirteen years 1908-20 inclusive he was able to collect only 40 outbreaks of typhoid fever due to milk, 4 of scarlet fever, and 3 of diphtheria; in the previous thirteen years he found 138 outbreaks of typhoid, 36 of scarlet fever, and 19 of diphtheria. Records of outbreaks of sore throat, however, have been more numerous (4 in the earlier period and 16 in the later). It would be hasty to assume—and Dr. North does not do so—that the diminution is wholly due to pasteurization of milk. The figures relate not only to America but to other countries where pasteurization is not so general. In this country, from which typhoid has for the time at least almost disappeared, account has to be taken of improved water supplies, control of the sale of oysters and of other shellfish, and various other factors. Dr. Hamer's observations on the subject have to be borne in mind, and

probably an epidemiologist would hesitate to accept too readily any single factor in explanation of the change.

With regard to infant mortality, Dr. North, like other contributors to the volume, calls attention to the incompleteness of vital statistics in the United States. He writes that "Chicago records are not given because infant births are not recorded." That is a most amazing fact for the second largest city in America. He goes so far, however, as to declare that before health authorities became active "more than half of the infants born perished during the first year of life." Mention is not made of the data on which this strong statement is based.

Milk Preservation.

With regard to the preservation of milk, it is stated that without any precautions whatever excepting cleanliness in production and cold in preservation milk sent from America every two or three weeks to the Paris Exhibition of 1900 kept sweet a fortnight after bottling, in striking contrast to French exhibits of milk. Raw milk of this purity is "certified" in part of New Jersey by a Medical Milk Commission. The considerations are bacterial condition, keeping qualities, and resistance to fermentation, nutritive value, and chemical composition. But the total quantity of available certified milk is small, some serious outbreaks have occurred in course of its use, and some certified herds have been found infected by tuberculosis on a large scale, so that most public health authorities prefer pasteurization. Yet Dr. North himself has great confidence in the possibilities of cleanliness. "As further evidence of the fact that methods and not equipment are the primary factors in producing clean milk," Dr. North "transported ten dairy farmers from their homes into a new dairy district, where in ten barns of the ordinary type, entirely strange to them, with no changes in equipment, these men produced milk within the limits of the certified standard for bacteria of 10,000, compared with milk containing many millions of bacteria produced in the same places the previous day by the owners of the premises." Independently of whether pasteurization is resorted to, the principles of clean production have been largely adopted, and most of the Grade A milk used in large cities is now produced by this system. As to pasteurization, he expresses the opinion that it should be done not domestically, but on a large scale for cities, and states that many such cities have followed the lead of Chicago and adopted regulations requiring pasteurization. In many smaller cities opinion is still divided, although public health authorities are practically unanimous in its favour.

Infant Milk Dépôts.

As an indication of the development of infant milk dépôts in America, he mentions that in New York fully 27,000 babies are enrolled at the stations of the Department of Health and over 6,000 at private agency stations. The death rate among enrolled babies is less than 50 per 1,000 births, and a reduction of 10 per cent. in the previous rate is not uncommon. The question whether such a reduction is due to milk or to education was, it is considered, answered in 1912 by a report of observational work done under the Rockefeller Institute, the feeding of large groups of infants on different milks having the following results:

Milk.	Mortality.			
Condensed	20 per cent.
Store	19 "
Good bottled	9 "
Milk dépôt	2.7 "

Opinions differ, however, one medical authority concluding that of a 60 per cent. reduction in mortality 15 per cent. was due to education and 45 per cent. to milk, while another held that if the total reduction is represented by 100, then only 20 per cent. of it was due to milk and 80 per cent. to training of mothers. On these differences Dr. North remarks that the conditions in the two groups were not the same, the milk in the former case being completely prepared for use, while in the latter nurses instructed the mothers how to prepare it. In laboratory work chemical testing is done by the Babcock method (sulphuric acid), which in America is universally considered the standard, and it can be used by any intelligent superintendent. In bacterial testing the count occupies the first place, and confidence in such testing is increasing. Five samples of the same milk are required to give a reliable result, placing the milk in Grade A, B, or C.

(To be continued.)

GLASGOW ROYAL INFIRMARY: VIEW FROM THE SOUTH-EAST.
(Reproduced from an architectural drawing.)

NINETIETH ANNUAL MEETING of the British Medical Association, GLASGOW, 1922.

THE MEDICAL INSTITUTIONS OF GLASGOW.

LET Glasgow flourish by the preaching of the Word"; "The poor were visited gratis and the Faculty adjourned." In these two phrases—the first, the motto of Glasgow, the second, the time-honoured formula with which every minute of the Royal Faculty of Physicians and Surgeons concludes—lies the spirit which has actuated Glasgow's citizens and Glasgow's doctors in founding and building, maintaining and staffing its many medical institutions.

It is a far cry in time from the Hospital of St. Nicholas of 1471 to the Royal Infirmary of 1922, but they are still together in space, in the same square—the one, the oldest house in Glasgow, plain, small-windowed, low-roofed, with walls restrengthened, a house for show; the other, lofty, baronial, busy with the activity of healing and teaching. A score of years after Robert the Bruce died of leprosy in 1329, the Leper Hospital of St. Ninian was built, close to the river, on its southern side; now only Hospital Street and St. Ninian Street unattractively preserve locally the memory of the founder, Lady Lochoy. Exactly six centuries after the Hero King fought Bannockburn, King George, in 1914, four weeks before the beginning of the greatest of all wars, opened Glasgow's newest hospital—the Royal Hospital for Sick Children—again close to the river, crowning a hill, overlooking docks and shipyards, with a wide view of the lower Clyde valley and the western mountains. It is a long notable history of achievement and service. The Glasgow doctors originated the hospital ideas, and the public spirit of the people of Glasgow readily expanded them into material, planning, and building. The initiation of the scheme for building the first Royal Infirmary is credited to Jardine, the Professor of Logic, eagerly supported by Dr. Stevenson, the Professor of Medicine; the Eye Infirmary owes its birth to Dr. William Mackenzie, one of the greatest ophthalmologists of his day; the Victoria Infirmary arose through efforts of the doctors on the south side of Glasgow; and the Royal Hospital for Sick Children came into being largely through the influence of Dr. Finlayson, one of Glasgow's greatest clinicians.

While we remember these, we must not forget the part played by the citizens of all classes of society. Some names at once spring into evidence: the brothers John and James Templeton, of carpet-making fame; Robert and James Dick, the gutta-percha manufacturers; Edward Davies, John MacFarlane, David McCowan, John Free and of Nice, William MacEwen, a distinguished merchant popularly called "the horse of knowledge"; Walter Couper of Cathcart, and Miss Schaw, are only a few of those who, out of their wealth and organizing ability, gave freely to the voluntary hospitals. All that they did carried the work but a little way, and it is to the great mass of the nameless ones of Glasgow in its industrial areas and in its commercial centres that the city after all owes its long and magnificent hospital record.*

* Previous articles, on the City and University of Glasgow and its neighbourhood, have appeared in the BRITISH MEDICAL JOURNAL of December 3rd, 1921, p. 951, January 7th, 1922, p. 29, February 11th, p. 242, and April 22nd, p. 642.

THE GLASGOW HOSPITAL SYSTEM.

The hospital system of Glasgow may be partitioned off into five or six different classes.

First in order of time as well as in the affection of the people and medical profession of the city stand the great voluntary hospitals, both general and special. All of these cannot be noticed, but even the smallest of them holds a place in active life and charity.

Next come the municipal hospitals under the governance of the Corporation of Glasgow, famous the world over for municipal enterprise from the far-off days of 1859, when the waters of Loch Katrine were brought to Glasgow, down to the present when the street tram system is an object of envy to other cities. The Health Committee, in association with Dr. Chalmers, M.O.H., shoulder this great responsibility.

In the third class we place the hospitals under the Poor Law authorities, the Parish Councils, and District Boards of Control.

The fourth class has one hospital, the Glasgow Royal Mental Hospital at Gartnavel—a private institution, but governed by a body of directors.

Then we think that into a fifth class, standing also by itself, may be placed the Princess Louise Scottish Hospital for Limbless and Disabled Soldiers and Sailors at Erskine.

And last of all the private nursing homes of Glasgow deserve a place, playing as they do a large part in the intimate life of the well-to-do people of the city.

THE VOLUNTARY HOSPITALS.

When the British Medical Association met in Glasgow in 1888, the old "Royal," designed by the brothers Adam nearly a hundred years before, was still feeling acutely the movement westwards of the University, though to the people of Glasgow it was The Infirmary. It was there, only twenty years before, that Lister was carrying on that great task which inaugurated the new era in surgery. And it was there that many members of the Association crowded the wards to see the work of Maccewen, brilliant in conception and daring in originality.

The Royal Infirmary of To-day.

This year the Association will find a new "Royal" that has arisen phoenix-like out of the ruins of the old, and they will find it modern, thoroughly equipped and hard-working, striving to live up to its great reputation. The nominal number of beds in the infirmary is 665, though its daily average of patients is always higher. There are five physicians, six surgeons, and special departments in gynaecology, ear, throat and nose, and skin diseases, and pathology. Each physician has charge of two large wards with ample side-room accommodation and an excellent classroom and clinical laboratory; each surgeon has three wards and operating theatre arranged on one flat, with an average number of patients of 52. The medical officers attached to the infirmary number 105, and there is a nursing staff of 270. The out-patient department deals with many thousands of patients in the year. The electrical department is a large organization with a staff commensurate to the great and increasing needs of this kind of work. From 1794, when the Royal Infirmary was opened, till 1874, it was the only hospital available for instruction in clinical medicine and surgery in Glasgow; after the removal of the University from High Street to Gilmorehill in the west end of the city the Royal Infirmary ceased to be used for clinical purposes except for students attending Anderson's College. It was then felt that a school of medicine worthy of the infirmary should be instituted, and in 1882 buildings

were completed to the north of the old infirmary; for many years this school was attended by students desirous of obtaining the triple qualification of the Royal Colleges of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow. In due time St. Mungo's College was instituted, the number of classes was increased, and a Faculty of Law was formed with an adequate staff. In 1911 the definite association of the Royal Infirmary with the university was re-established, and there are now in the infirmary four university professors in medicine, surgery, midwifery, and pathology. Thus the infirmary is crowded once again with students, both men and women, who find in its wards and out-patient departments abundant opportunities for the study of disease and a wealth of clinical material probably unsurpassed.

Plans for the working of the infirmary on a part-time unit system are being considered, and if these come to fruition the training of students and the junior staff will assuredly strengthen the already sound position of the Glasgow school.

The Royal Infirmary possesses another distinction: it has the great merit of having closed its last two financial years with a surplus. When it is considered that the ordinary expenditure in 1921 amounted to £118,250 (the average cost of each fully occupied bed being for that year £171 19s. 7½d.

and the average cost of each patient under treatment £10 16s. 2½d. for an average residence of twenty-three days), and that huge expenditure was met with some hundreds of pounds to the good, it will be readily understood that the skill and watchfulness of the management are only equalled by the extraordinary generosity of the people of Glasgow and their anxiety to preserve the voluntary principle of hospital management. As the result of efforts in for seeking the industrial workers of Glasgow the large sum of £30,000 was subscribed in 1921 by this class of subscribers alone. Legacies still continue to fall to the infirmary. These should go into the capital account, but the needs of current expenditure divert them to this use, and it is possible that this source of revenue in these difficult times is more likely to dry up than increase in the volume of its stream.

In bottom left-hand corner is the old Lister Ward.
(Photograph by T. and R. Annan and Sons)

The Western Infirmary.

When the University removed to the western portion of the city it soon became evident that an infirmary was required close to it for the purposes of clinical teaching. The Western Infirmary was opened in 1874 and has been added to repeatedly since. In 1904 the new out-patient department was opened; in 1906 and 1911 new wings were added to the main building of the infirmary; in 1913 the Pathological Institute was enlarged, and in 1921 a massage building was erected. It is evident therefore that the Western Infirmary is keeping pace with the demands made upon it, both for the treatment of the sick and for the teaching of students. There are thirty-two wards in the infirmary, four services of medical wards, and six services of surgical wards, with wards for various specialties. The medical and surgical staff number 60; each surgeon has his own theatre on the same flat and in close proximity to his wards; there is a nursing staff of 226. In 1921 the average daily number of in-patients was 557. The Western Infirmary is blessed with a beautiful situation, a southern exposure with a large open space in front, and its grounds adjoin Kelvingrove Park. The close proximity of the University is a time-saving factor of great value to students. The infirmary is fortunate in the possession of an excellent convalescent home, the gift of Lord Newlands; the home is situated in Lanark, a town renowned for its fresh upland breezes. The successful management of the Western Infirmary is due in great measure to the organizing ability

and knowledge of hospital construction possessed by the Superintendent, Colonel D. J. Mackintosh, C.B., M.V.O., LL.D., M.B., one of the foremost hospital authorities in the kingdom.

The Victoria Infirmary.

The Victoria Infirmary is the third of the large general hospitals in Glasgow; it is very pleasantly situated on the southern outskirts of the city, almost on the site of the battlefield of Langside, where Mary Queen of Scots was defeated by Regent Moray. The infirmary grounds are extensive and its amenity is increased and rendered more attractive by its proximity to the Queen's Park. The infirmary was opened in 1890, with accommodation for 60 patients; the increases have been steady till now the nominal number of beds is 260. The visiting staff consists of three surgeons, with four assistant surgeons, and two physicians, with four assistant physicians; there are also special wards for gynaecology, nose and throat, and skin diseases. There is a large outpatient department, which is situated in a densely populated portion of the city near the docks; this department is known as the Bellahouston Dispensary, and there the number of attendances is estimated, as in most infirmaries, in thousands. The infirmary possesses an excellent clinical research laboratory, the gift of a well-known shipowner of the city. The convalescent home is at Largs, on the Firth of Clyde,

natal wards, and 2 labour wards; the 114 beds are divided therefore into 89 obstetric beds and 25 ante-natal beds. The hospital staff consists of six visiting physicians, five assistant visiting physicians, one pathologist, and one physician at the gynaecological dispensary. There is an outdoor department from which patients are attended at their own homes by district nurses and students, and there are three outdoor dispensaries—gynaecological, ante-natal, and post-natal. An important auxiliary to the hospital is the maternity and child welfare centre, consisting of a complete indoor and outdoor ante-natal department and infant consultation clinic. In recent years the research department of the hospital has come into prominence for its most excellent work. By arrangement with the Medical Research Council the department was opened towards the end of 1919. The Royal Maternity Hospital is on the voluntary basis entirely, and, like the other great hospitals of Glasgow, depends largely on subscriptions from the industrial workers of the city. Both in this hospital and in the others workmen's representatives on the boards of directors are found to be men capable of taking broad, sensible views and possessing sound business capacity.

Royal Samaritan Hospital.

The Royal Samaritan Hospital was established in 1886 and meets the needs of a very large number of women of the

THE WESTERN INFIRMARY, GLASGOW.

(T and R. Anatomical Soc.)

and has accommodation for 30 patients. It is only within the last two or three years that, owing to the large number of students, the Victoria Infirmary has been able to take its rightful place in clinical teaching. The distance from the University and from the centre of the city is a somewhat serious matter and has hitherto deterred the student. Within the past year a most excellent scheme for the expansion of clinical teaching has been inaugurated, the funds subscribed by a few generous donors yielding an income sufficient to establish a post-graduate school.

Royal Maternity and Women's Hospital.

The Glasgow Royal Maternity and Women's Hospital possesses 114 beds and is probably one of the largest, as it is certainly one of the most thoroughly and efficiently equipped, maternity hospitals in the kingdom. It was founded in 1834 and its beginnings were modest. The first hospital found a home in the second flat and garrets of the old grammar school at a rental of £30 a year. The early years of the institution revealed a constant struggle against the outbreaks of septic infection, and it was not till 1860 that a house at the corner of North Portland Street and the Rottenrow was purchased for a new hospital and the building adapted for that purpose. Conditions still were unsatisfactory, and in 1881, on the same site, the maternity hospital was built. This building still stands. It was in this building that Murdoch Cameron first performed the noteworthy and successful Caesarean sections which put that operation on a sure footing. In 1903 the present hospital was opened; it contains 19 wards, which are apportioned into 12 lying-in wards, 3 isolation wards, 2 ante-

working classes, belonging mostly to the southern portion of the city. It has accommodation for 92 patients; there are four surgeons, all of whom are gynaecological surgeons in private practice. A feature of recent years has been the excellent facilities for post-graduate work offered by the hospital, and these have been largely taken advantage of, not only by local practitioners but by practitioners overseas.

Royal Hospital for Sick Children.

The Royal Hospital for Sick Children stands on a piece of rising ground where once stood the mansion house of Yorkhill. It is admittedly one of the finest hospitals for children in existence. We have already indicated the excellence of its site from the scenic point of view. Let it be noted, too, that it is within five minutes' walk of the University and the Western Infirmary. The hospital contains twelve wards and has accommodation for nearly 300 patients, one-third of whom are medical and the rest surgical; the patients must not be over 15 years of age. The hospital draws upon a large area, which includes not only Glasgow but the whole of the west of Scotland. A few figures will show the large amount of work which is done in this institution: in 1921 the indoor patients numbered 4,749; the outpatients seen at the hospital were 2,162; while at the old dispensary—which is nearer the centre of the city—14,769 patients were treated in that year. The visiting staff consists of one physician with four assistants, two surgeons with six assistants, and there are three visiting specialists; the nursing staff numbers 102. This hospital, again, is maintained by voluntary subscriptions. The expenditure during 1921 was

a little over £34,000. Of recent years considerable attention has been given in the research department of the hospital to the etiology of rickets and to syphilis in infancy. The country branch of the hospital is situated at Drimchapel, about six miles to the west of the city.

The Eye Infirmary and Ophthalmic Institution.

There are two main hospitals for diseases of the eye. The Eye Infirmary is situated in Berkeley Street, its original site, where in 1824 it was founded by one of its first surgeons, Dr. William Mackenzie; the building has been altered, and additions have been made from time to time. It has accommodation for 105 indoor patients, and there is a large out-patient department. An important adjunct to the infirmary is a second out-patient department at Charlotte Street, in the east end of the city, recently rebuilt.

The Ophthalmic Institution constitutes the department for the diseases of the eye of the Royal Infirmary, and is managed by the Directors of the Royal Infirmary. This institution owes its origin to Wolfe. It is situated in the centre of the business portion of the city, in West Regent Street.

These two institutions see many thousands of patients in each year, both in their indoor and in their outdoor departments.

Glasgow Hospital for Diseases of the Ear, Nose, and Throat.

Before the three large general hospitals developed a special department for these diseases, the Glasgow Hospital for Diseases of the Ear, Nose, and Throat had been established for a considerable length of time. Like many other of the hospitals, indeed, like the majority of the hospitals of Glasgow, it owes its origin to the medical profession. In 1872 the late Dr. J. P. Cassells opened a dispensary which was called the Glasgow Dispensary for Diseases of the Ear; this ultimately developed into the Glasgow Ear Hospital and from 1880 dealt with indoor patients as well as outdoor. Dr. Andrew Buchanan was at that time president of the hospital and maintained an intense interest in its work. The hospital is situated in Elmbank Crescent, where it has been since 1885. The large increase in the amount of work of late years has firmly impressed the directors with the necessity of finding new premises. An excellent site in St. Vincent Street, close to its junction with Bothwell Street, has been obtained, and it is hoped that within a very short time the new building will be begun. It is unnecessary to do more than indicate that the hospital attendances number many thousands in the year, and the work taxes the energies of the two visiting surgeons and four assistant surgeons to the uttermost. In spite of limited accommodation (the number of beds is only 15) the hospital affords a most excellent clinic, both for students and graduates. This hospital had the enviable distinction of possessing a substantial balance in the bank at the end of the last financial year.

Glasgow Royal Cancer Hospital.

The Glasgow Royal Cancer Hospital is comparatively new, as it was rebuilt and completed during the year 1910. It is situated in the Garnethill district of the city, a few minutes' walk from the University. There are 50 beds in the hospital, and the staff consists of two surgeons, two assistant surgeons, a medical electrician, and a pathologist. There is no outdoor department. The number of patients treated in 1921 was 245. An important part of the work of this hospital is research; the directors and staff have no desire that the hospital should be regarded simply as a Friedenheim, where advanced cases of malignant disease may terminate their lives with some mitigation of their sufferings. The research department has been in serious financial difficulties since the

close of the war, but recently a liberal donation helped to re-establish its work.

MUNICIPAL HOSPITALS.

Prior to 1865 infectious fevers were treated in the wards of the various poorhouses, the Glasgow Royal Infirmary, and in temporary hospitals occasionally erected to meet emergencies. The first Municipal Fever Hospital was opened in that year in Kennedy Street, off Parliamentary Road, and the second was Belvidere Hospital, at the eastern boundary of the city, opened in 1870. Since 1875 the local authority has been wholly responsible for the provision of accommodation for the treatment of infectious diseases. Besides making provision for fevers and the other diseases included in the zymotic group, the local authority has also made provision at Ruchill, Knightswood, and Robroyston Hospitals for patients suffering from tuberculosis in all its forms. The hospital beds available for infectious diseases in Glasgow have gradually, though not regularly, increased, till in 1921 there were 1,262 beds, which, in relation to the population, means 1.1 per 1,000.

In the six hospitals—Belvidere, Ruchill, Shieldhall, Knightswood, Robroyston, Bellefield—there is a resident medical staff of twenty-one and a resident nursing staff of 577; in addition there are an honorary consulting surgeon and three consulting surgeons, of whom one is visiting surgeon for tuberculosis; there are also a part-time radiologist for tuberculosis and a part-time specialist for venereal diseases and trachoma.

As regards the institutional accommodation for patients suffering from tuberculosis the total number of beds in the various hospitals and sanatoriums under the control of the authorities is 975, and if we add to this figure an average of 240 beds available in Poor Law institutions we find the total for tuberculosis patients in institutions is 1,404 beds.

HOSPITALS ADMINISTERED BY THE PARISH COUNCILS OF GLASGOW AND GOVAN.

The parish of Glasgow is the most populous in Scotland, the 1921 census showing it to have 596,085 inhabitants. The parish council controls the administration of one large general hospital, two district hospitals,

a poorhouse, two seaside homes for adults and young persons, and two homes at the coast for children.

For cases of insanity the District Board of Control has two large and fully equipped hospitals for mentally deficient persons, practically the only institution in Scotland specially erected for the purpose.

In addition to the treatment of the indoor poor of the parish, including the boarding of children and harmless lunatics in private dwellings all over the country, the parish council has a roll of over 19,000 adults and their dependants chargeable throughout the year.

In 1921, for the first time in the history of the Scottish Poor Law, parish councils gave financial assistance to the unemployed, the amount up to the end of May, 1922, being £183,000. The total amount expended in ordinary Poor Law relief and lunacy within the parish was roughly a million pounds sterling for the past year.

The Northern General Hospital, Stobhill.

The Northern General Hospital, Stobhill, is the largest and most up-to-date Poor Law institution in Scotland. It was held available for military purposes, and on the outbreak of the war in 1914 it was converted into two military hospitals—the 3rd and 4th Scottish General Hospitals. The site of the hospital is an ideal one on a large elevated piece of ground in the northern side of the city, with an admirable outlook towards the hills in the west and north. The institution has accommodation for nearly 2,000 patients, including children, and is divided into wards in separate blocks for medical, surgical, infirm, and children's departments under a medical superintendent, with, in addition, a visiting physician, surgeon,

THE ROYAL MATERNITY AND WOMEN'S HOSPITAL, GLASGOW.
(Photograph by T. and R. Annan and Sons.)

dentist, oculist, pathologist, and four resident medical officers. The total cost of the land and buildings opened in 1902 was half a million pounds.

The Eastern and the Western District Hospitals.

The Eastern District Hospital and the Western District Hospital are intended primarily for acute curative cases, both medical and surgical. There is a medical superintendent with a visiting physician and visiting surgeon. A special feature of the Eastern District Hospital is the wards for the treatment of incipient mental diseases; these wards are regarded as unique in Scotland, and serve the purpose of preventing many patients being sent to asylums. The Eastern Hospital has accommodation for 320 patients; the Western has accommodation for 225 patients.

Barnhill Poorhouse, Springburn.

The Barnhill Poorhouse is utilized chiefly for infirm patients and recurring sick; it has accommodation for 2,000 patients or thereby, with an adequate staff of medical officers and nurses. Its situation is unfortunately the dingiest in Glasgow, surrounded by ironworks.

Glasgow District Asylum, Woodilee, Lenzie.

The Glasgow District Asylum at Lenzie is one of the largest mental hospitals, and, with its succursal establishments, accommodates 1,292 patients. It is built on an estate of nearly 800 acres, and gives ample scope for open-air and curative treat-

GLASGOW ROYAL MENTAL HOSPITAL, GARTNAVEL.

The Glasgow Royal Mental Hospital is worthy of special mention, though it is in a sense a private hospital; it accommodates approximately 500 patients, whose rates of board vary from £58 to £600 per annum. The building is a large one, in the western portion of Glasgow. The average number of patients treated annually for the last four years was 492. There is ample scope for outdoor exercise and recreation, a golf course, tennis courts, croquet lawn, and a curling pond being provided. The laboratory of the Western Asylums' Research Institute is situated within the hospital grounds, and research into the etiology and results of mental diseases is carried on there.

The history of the asylum, as it used to be called, is of great interest. It owes its origin at the beginning of the nineteenth century to the efforts of one gentleman, Robert McNair, of Belvidere, Glasgow. As a director of the town's poorhouse he was horrified by the wretched condition of the insane, who, whatever their social position, were kept in "the cells" at the poorhouse on the banks of the Clyde. After years of work he saw the foundation-stone of the "Glasgow Asylum for Lunatics" laid in 1810. For many

Edinburgh (A.P.)

ERSKINE HOUSE.

T. and E. Anderson & Sons.

ment. It is situated a few miles outside the city, on the North British line to Edinburgh. The sanatorium pavilion is of modern type.

Glasgow District Asylum, Gartloch, Gartoosh.

The Glasgow District Asylum at Gartloch is a newer building than Woodilee, being opened in 1855; the building is situated about eight miles from the city, within its own grounds, which extend to 440 acres, and its accommodation provides for 812 patients.

Institution for Mental Defectives, Stoneycetts, Chryston.

The Institution for Mental Defectives, Stoneycetts, has accommodation for 345 patients, and is built on the lands of Woodilee Asylum, about two miles or thereby distant from that building.

The parish of Govan comprises a second portion into which greater Glasgow for Poor Law purposes is divided. The burgh of Govan and the burgh of Partick were until recently municipalities independent of Glasgow, but now they are merged. It is these two burghs with Tradeston and Kinning Park which mainly form the parish of Govan, representing the large population of 372,000.

The Southern General Hospital, Merchiston.

This is the new title of the hospital known for many years as Govan Combination Poorhouse and Asylum. The hospital was founded in 1845 and housed in an old mill in Dale Street, Tradeston. In 1853 it was transferred to Port Eglinton (a location known to few in these days) to a building once used as a cavalry barracks for the southern district of Glasgow. The present building was erected in 1872 in the most westerly portion of the parish on the south bank of the river lower down than the great shipbuilding yards of the Fairfield Company. There are about 2,000 beds in the hospital, with wards for mental defectives, chronic and incipient insanity cases, epileptics, patients suffering from venereal and skin diseases, maternity cases, as well as for the ordinary medical and surgical patients. The medical staff consists of a medical superintendent and three assistant medical officers, with a large nursing staff. There is a small convalescent home for children in the island of Bute.

years this institution was regarded as a model asylum. The present Royal Asylum, or, to give its new title, the "Royal Mental Hospital," was opened in 1843. The building is not now of the most modern type, but in those days it was in advance of its time. The physician-superintendent is University Lecturer on Insanity: the clinical field is very large.

THE PRINCESS LOUISE SCOTTISH HOSPITAL FOR LIMBLESS AND DISABLED SOLDIERS AND SAILORS, ERSKINE.

It is intended that a special excursion will be organized to visit the Princess Louise Scottish Hospital for Limbless and Disabled Soldiers and Sailors at Erskine on one of the afternoons of the meeting in July. This hospital is situated on the banks of the Clyde, about ten miles from the centre of the city. Erskine House is a stately mansion, with extensive grounds sloping to the left bank of the river. Thanks largely to the generosity of Sir John Reid, Deacon Convener of the Trades' House of Glasgow, the mansion was acquired for its present purpose. It was opened in 1916, and it is due to the untiring efforts and influence of the President-elect of the Association, Sir William Macewen, that the hospital has become the efficient complete organization which it now is. It first serves the purpose of a preparatory hospital for the readjustment of stumps and their surgical demands; secondly, it provides for the manufacture and fitting of artificial limbs and appliances, and teaches the men their full and proper use; in the third place, the men are trained in trades suitable to the degree of their disablement. The workshops for the manufacture of artificial limbs and provisional limbs have already provided 10,000 limbs. The hospital has been recognized as a Government training centre for the various trades. At the present time 110 men are undergoing training, and 126

men have already completed their training and are working in various parts of the country. There is accommodation for 400 men, half of the beds being in temporary premises. There is a well-equipped operating theatre and x-ray department. The surgical staff is drawn from the surgeons of the voluntary hospitals of the city, who visit the hospital at regular intervals.

NURSING HOMES IN GLASGOW.

Any notice, however imperfect, of the medical institutions of Glasgow would be incomplete without a reference to the very numerous and well-equipped private nursing homes. As in other cities, these homes are generally the private property of ladies who are trained nurses and who have gathered around them adequate and efficient staffs. These homes have been established in private houses which have been altered to suit their new purposes. Many of the large terrace mansion houses of the west end of Glasgow have been acquired, and, generally speaking, have fulfilled the purpose of a private hospital admirably. All the nursing homes have completely equipped operating theatres, and the surgeons of Glasgow carry out their private work with perfect confidence in the efficiency of the nursing and in the completeness of the aseptic technique. The first home to be established was the McAlpin Home. Miss McAlpin very early recognized that there was no institution suitable for the non-hospital class, and in 1874 she founded the home for the training of nurses, having acquired a private house in Renfrew Street—one of the backwaters of Glasgow, but very near the main thoroughfares. In 1908 a new building was erected, and, although the plan is incomplete, the portion which has been constructed, comprising as it does an excellent series of private rooms each with a small balcony and southern exposure, and a beautiful operating theatre with roof light from the north, provides in itself a private hospital of modern type. The McAlpin Home is managed by a board of directors, and is not run for profit. Any surplus accruing is used for the building extension fund. It is the largest establishment of its kind in Glasgow, and can accommodate 50 patients.

Glasgow is much in need of a hospital, similar to those established in Birmingham and in Bristol, where patients may be accommodated and treated for a moderate inclusive fee, and it is hoped that in the near future some such establishment will be erected.

Nova et Vetera.

SIR ROBERT SIBBALD'S LIBRARY.

SIR ROBERT SIBBALD died in 1722 in his 81st year. He was a nephew of Sir David Sibbald, knight-baronet of Rankeillour in Fife, and keeper of the great seal under the chancellorship of the Earl of Kinnoull. He was born in Edinburgh in 1641, but went to school in Ompar, Fife. In 1651 he was in Dundee with his parents when that city was besieged by Monk, and he narrowly escaped with his life. He was then sent to the High School of Edinburgh and had five years in the university there; he was studying theology at the time, but he changed to medicine for the reason that he "preferred a quiet life not engaged in factions of church and state." That he might "see the world and know men," he studied at Leyden and took the degree of M.D. there in 1661, and he was also at Paris and Angers.

He returned to Edinburgh to practise medicine in 1662; in 1667 he, along with Dr. Andrew Balfour, instituted a botanical garden; he was chiefly instrumental in founding the Royal College of Physicians of Edinburgh in 1681, and became its President in 1684; in 1682 he was appointed physician to Charles II and geographer for Scotland; in the same year he was knighted by the Duke of York; and in 1685 he was made first professor of medicine in the university by the Town Council. He was elected a member of the College of Physicians in London during the short period of his practising there in 1686. In 1697 he presented his natural history collection to the university; but his magnificent library was disposed of by sale in 1723.

The Catalogue was prepared in 1722, and the title-page is as follows:

"*Bibliotheca Sibbaldiana: or a Catalogue of Curious and Valuable Books: Consisting of Divinity, Civil and Ecclesiastical History, Medicine, Natural History, Philosophy, Mathematicks, Belles Lettres, &c. With a curious Collection of Historical and other Manuscripts. Being the Library of the late Learned and Ingenious Sir Robert Sibbald of Kippis, Doctor of Medicine. To be Sold by Way of Auction, on Tuesday the 5th of February 1723, at his House in the Bishop's Land in Edinburgh; where Placards will be affix'd. The Time of Sale is to be from Two of the Clock to Six in the Afternoon. The Books may be seen Eight Days before the Auction. Catalogues are to be sold for a Sixpence each, at William Brown's, and most of the Booksellers Shops in Edinburgh, and at the Place of Sale. Edinburgh, Printed in the Year MDCCXXII.*"

The "Conditions of Sale" contained some curious clauses; for example, No. IV reads: "They who buy Books to the Value of 10 shillings sterl. shall have the Sixpence they paid for their Catalogue, returned, or discompted to them." No. V, too, reads: "The Books (not otherwise expressed) are supposed to be perfect; but if any of them appear to be otherwise before they are taken away, the Buyer shall have his Choice either to take or leave them."

The Bishop's Land, where this historic sale took place, was a famous edifice on the north side of the High Street, which had got its name from having been the town residence of John Spottiswood, Archbishop of St. Andrews and Primate of Scotland in 1615. From this house the Archbishop had gone to crown Charles I at Holyrood in 1633, and from this house he fled in 1637 when the Scottish people rose against the introduction of the liturgy and Jenny Geddes threw her stool in St. Giles. In this mansion, too, lived (but after Sibbald's time) Lady Jane Douglas, heroine of the Douglas cause; there also resided the first Lord President Dundas, and there his celebrated son, Henry Viscount Melville, was born in 1741, some nineteen years after the sale of the *Bibliotheca Sibbaldiana*. The tenement was destroyed by fire in 1814.

The catalogue has 140 pages and contains the titles of about 5,400 books along with those of 114 historical manuscripts and 33 miscellaneous ones. The particular copy of the catalogue in the writer's possession is finely bound in calf and has 24 pages of plain paper included at the end. The book bears the stamp of the *Bibliotheca Heberiana*, showing that it once formed part of the immense collection of Richard Heber (1773-1833), the bibliophile, whose literary treasures occupied "eight houses, overflowing all the rooms, chairs, tables, and passages." It also bears the name "D. Laing," probably the Scottish antiquary (1793-1878) into whose possession it may have passed at the time of the dispersal of the Heber Libraries (1834-35). Its special value is in the fact that the prices the books fetched are marked in on one margin of each page in ink in a contemporary hand, whilst on the opposite margin are here and there faint pencil notes of prices which do not always come up to those on the other margin. The conclusion would seem to be that the catalogue belonged to a bidder at the sale who did not always secure the treasures he was trying for. One can thus almost reconstruct the progress of the sale in some of its details.

The historical MSS. were acquired by another Edinburgh library, as a written note on one of the blank pages at the end of the catalogue records: "Sold all the Manuscripts att £260, bought for the Library of the Faculty of Advocates." From the wording of this note it might almost be concluded that the particular catalogue belonged to William Brown or to Gavin Drummond, "Booksellers in Edinburgh and Managers of the said Auction." If so, the pencil prices may have been commissions undertaken for customers at a distance. It is interesting to observe that amongst the MSS. thus disposed of were "Memoirs for Compiling the History of the Royal College of Physicians at Edinburgh" by Sir Robert Sibbald himself. This was printed in 1837. "Opera Philosophica" and "Poemata," both by George Sibbald, also appear among the MSS.; these were the work of Dr. George Sibbald, the medical uncle of Sir Robert, who advised that he should be suckled for two years because his older brothers and sisters "had died hectic." There were also in MS. "A Description of the Islands belonging to the Crown of Scotland," "Collection of Papers and Informations, in Order to the Description of Scotland," "Provinciae Edinburgensae Descriptio," and "Chronicon Melrossense"; these all remind one that Sir Robert had been appointed in 1682 "Geographer of Scotland." Any observations on the medical books and other bibliographical treasures disposed of at this sale two hundred years ago must be deferred to some other occasion.

British Medical Journal.

SATURDAY, JUNE 3RD, 1922.

THE GLASGOW MEETING.

THE ninetieth annual meeting of the British Medical Association will be held at the close of next month in Glasgow, under the presidency of Sir William Macewen, F.R.S., Regius Professor of Surgery in the University of Glasgow. The Association is fortunate alike in its meeting place and in its president. Glasgow is a great centre of medicine, an ancient university town, and the magnitude of its commerce and shipping has earned for it the title of the second city of the Empire. Sir William Macewen's renown as a scientific surgeon and clinical teacher is world-wide; his name and work are part of the history of modern surgery. An article on the medical institutions of Glasgow appears at p. 883 this week, and a full account of the arrangements for the forthcoming meeting is published in the SUPPLEMENT.

Thirty-four years have passed since the British Medical Association met in Glasgow. The President then was Professor (afterwards Sir William) Gairdner, who, in opening his address to the Association on "The physician as naturalist," remarked that "as the healing art is probably the most cosmopolitan of the arts, so Glasgow is, beyond all doubt, as regards its commerce and its varied industries, one of the most cosmopolitan of cities." These words are as true to-day as they were in 1888, and the thesis sustained by the President of that year is not less applicable to the present time. His argument, in brief, was that tradition has demanded that the healer or physician of the highest class should also be in a very real sense of the word a naturalist, a man of science; that it is his prerogative to be trained and exercised after the best manner and according to the most thorough discipline of the science of his age; and that he has been, and should be, looked up to as a healer or physician chiefly in proportion to the confidence reposed in him as a naturalist—that is, a humble, reverent, and exact follower and student of Nature. Passing then from historical considerations, Professor Gairdner discussed certain defects (some of them still visible) in the system of medical education, and concluded that although the physician could never again become what he was in the early ages—the sole or chief representative of physical science—he must always be, and should become more and more, a man trained in its discipline and familiar with its resources. As the years pass and science advances the justness of this view becomes more and more plain.

In 1888 the Address in Medicine was given by Dr. (now Sir) Clifford Allbutt, then practising in Leeds; he dealt with one aspect of a subject in which all through his great career he has continued to show interest—namely, what may be briefly described as the application of the conception of evolution to the study of disease. The title of his address was, in fact, "On the classification of diseases by means of comparative nosology." The Address in Surgery was given by Sir George Macleod, and Dr. William Macewen (as he then was) gave an address on his recent investigations in surgery, dealing with the surgery of the brain and spinal cord. This was described in our columns at the time as "in many respects the most remarkable contribution to surgical literature which the present day has produced"; and again, that it marked "an epoch in surgery, the initial stage of a branch of our art obviously destined

to a glorious and beneficent future." After his address Dr. Macewen gave a demonstration of cases so remarkable that it alone would have sufficed to render the Glasgow meeting of 1888 memorable in the annals of surgery. Many of the patients whose cases had been described in the address were presented and their demonstration greatly interested the many surgeons who attended; perhaps the most remarkable case was that of a boy in whom the whole shaft of the humerus had been re-formed from grafts; the case is, we believe, well known to surgeons of to-day who take an interest in the history of orthopaedics. In recent years clinical and laboratory demonstrations have come to fill a larger place in the work of the Scientific Sections; and at the Association's second visit to Glasgow the afternoon sessions will be devoted to this purpose, thus following the plan so successfully adopted at Cambridge in 1920 and at Newcastle last summer.

The Sections in 1888 numbered twelve; this year there are nineteen. As will be seen from the programme printed in the SUPPLEMENT, many topics of interest and practical importance are set down for discussion by the Sections at Glasgow; in choosing them special heed has been paid to treatment, both medical and surgical, and to the problems of causation. In the Section of Medicine discussions on renal disease, on exophthalmic goitre, and on degenerative diseases of the liver, will be opened by a leading authority in each subject. The Section of Surgery for its principal debates has selected cholelithiasis, splenic and pituitary diseases, and non-malignant affections of the colon. In the Section of Pathology, Professor Fibiger of Copenhagen will introduce a subject with which his name is identified—the origin of cancer in relation to specific forms of irritation; the second morning will be devoted to animal and vegetable pathology. Another aspect of the comparative study of diseases in plants and animals will be considered by the kindred Section of Microbiology, whose varied bill of fare ranges from the bacteriology of influenza to the mutation of species, and whose afternoon demonstrations include one of leishmaniasis by Sir William Leishman. Psychotherapy and the treatment of neuro-syphilis are the main topics before the Section of Neurology and Psychological Medicine; and the Section of Ophthalmology will discuss optic atrophy and heterophoria. Stillbirths and neonatal deaths has been chosen for discussion by the Section of Obstetrics and Gynaecology, each aspect of the problem being brought forward by a representative worker; the second and third mornings are set apart for independent papers, principally on treatment. The Section of Public Health has spread its net wide, and profitable debates may be expected. These eight Sections—a larger number than heretofore—will meet on each of the three days, July 26th, 27th, and 28th. Five Sections will meet on two days each—Dermatology, Diseases of Children, Physiology, Industrial Diseases and Forensic Medicine, Radiology and Electrolgy. Of these the second and third have arranged a joint session to discuss rickets from the clinical and physiological sides; and the fifth will discuss deep x-ray therapy and the value of gas inflation in x-ray diagnosis. The remaining six Sections, each meeting on one day, are Anatomy, Anaesthetics, Laryngology, Otology, Tuberculosis, and Medical Sociology. The last named Section, it will be noted, proposes a debate on alcohol as a beverage in its relation to certain social problems.

The Annual Representative Meeting will open on July 21st. Here the parallel with the earlier Glasgow meeting fails, since the Representative Body is of more recent birth. The difference serves only to emphasize the development of the British Medical Association along lines already laid down in 1888, when, in the words of the late Dr. Farquharson, M.P., seconding the

adoption of the report of the Parliamentary Bills Committee, it had already advanced much further than "the scientific picnic state . . . and . . . become a great and important engine for upholding the honour and interests of the profession." For it may safely be asserted that no body less broadly democratic and representative in character and composition could hope to deal effectively with the work that lies before the Representative Body at Glasgow. That the promise of earlier times has so far been amply fulfilled is evidenced by the Annual Report of Council (published in the SUPPLEMENT of May 6th). The conditions of future progress remain to be determined, and will be influenced for some time to come by the decisions of the Representatives on the three main issues with which they have to deal—namely, the development of hospital policy, the development of medical services under the National Insurance Acts, and the maintenance of the accepted standards of professional secrecy under the pressure of an increasingly complex social system. All these are questions of the most vital importance to the future of medical practice in this country, and have been and are matters of keen controversy within the profession. They are also generally recognized as matters of immediate public concern, and it is this last feature which gives them peculiar importance. It is because the problems are pressing, and because rival solutions have already been suggested; some of them inimical to the standards which the Association exists to defend, that an immediate decision would seem to be essential. The Association has before it the double task of uniting the medical profession in support of a definite policy and convincing a critical and impatient public that that policy is governed by broad consideration of the common good, and not by the narrower dictates of professional interest.

As regards hospital policy, the Representative Body is not asked to come to a decision without ample opportunity for consideration. The report on the hospital policy of the Association (published in the SUPPLEMENT of February 25th) has been fully discussed in the Divisions and at the conferences of representatives of hospital staffs convened by the Association; it has excited also a lively correspondence in our columns. The complementary report on municipal hospitals (SUPPLEMENT, May 6th) is based on the principles adopted in 1921 at Newcastle in connexion with Poor Law infirmaries. Similarly, the matters of resistance to the encroachment of approved societies upon the position won in 1911 and apparently again to be contested, and of general approval of the continuance and improvement of the system of medical benefit under the National Insurance Acts, have already been dealt with by that large part of the profession most directly concerned. The Representative Body is now asked to set the seal of professional approval upon the policy laid down by the representatives of insurance practitioners. In connexion with professional secrecy the Council offers a modification of the resolution of the Newcastle meeting, designed to meet the difficulties that have emerged in giving practical effect to the original decision. One other subject of more than ordinary importance, though of a different kind, will come before the Glasgow meeting—the consideration of certain changes in the regulations of the Association necessary to give effect to the modification of its constitutional machinery decided upon last year at Newcastle. Of these, the provisions for the incorporation of Overseas Branches and the recognition of Federal Committees are of special significance, marking as they do the successful adjustment of a difficulty which had threatened the efficiency of the Association overseas.

So far we have spoken of the scientific and medico-political sides of the forthcoming Annual Meeting. After work, play. A glance at the list of entertainments and

other functions will show that the social side also is amply catered for. An attractive programme has been drawn up for each day, in accordance with the traditions of Scottish hospitality; and, besides excursions to places of interest in and near the city, members will be given opportunities to visit the beautiful West Highlands, to play golf, and to indulge in other outdoor sports.

GLYCOSURIA AND OBESITY.

A good example of the study of beginnings of disease by combined clinical and laboratory methods, and a good example also of team work, is afforded by some recent researches in the physiological laboratories of the Medical College, Calcutta. The team in this case consisted of the professor of physiology, the assistant professor, and three demonstrators.¹

The stimulus to institute a research is the existence of sufficient general information to show that there is a problem awaiting solution and to define its terms. In this instance the stimulus was afforded by the knowledge that diabetes was excessively common in India, especially on the eastern side—in Bengal, Orissa, and Madras. It was common knowledge also that the condition was far more prevalent among the well-to-do sedentary classes than among manual workers. It was so common that a Bengali said to one of the investigators, "A man is no gentleman if he does not pass sugar by the age of 40," just as in this country, when the habits of gentlemen with regard to sobriety were different, gout was exceedingly common among them in early middle life. The next general observation was that the Bengali gentleman who eventually became glycosuric was particularly apt to become obese while still young. "How often," the writers say, "have we seen students pass out from this college normal so far as the amount of adipose tissue present is concerned, yet in a few months or so many return almost unrecognizable on account of the mass of fat accumulated."

On commencing their investigations it was found that the average percentage of sugar in the blood of Bengali was 0.13, as against an average of 0.08 for Europeans, and that the percentage was higher (0.15) in the fat indolent classes than in the lean working classes, in whom it was 0.125. The sugar tolerance of the working classes proved to be high, whereas the fatter and flabbier the individual the lower his limit of tolerance. It was next ascertained that, apart from the tendency to fat deposit in the tissues there were personal variations in sugar tolerance: even a fat individual might show a high tolerance and a lean one a low. In those possessing a high carbohydrate tolerance the sugar content of the blood remained remarkably constant, but if the tolerance was low the amount of sugar in the blood was easily raised. Three classes of individuals were met with: first, those in whom the sugar content of the blood rose considerably on glucose ingestion, in whom the threshold of the kidney for sugar excretion was at a high level; secondly, those in whom the sugar content of the blood was about normal but who, on ingestion of glucose, developed glycosuria without any marked rise in the blood-sugar level; and, thirdly, those who developed glycosuria on ingestion of glucose without any rise in the blood sugar. It is conjectured that in the first class the glycogen-forming function of the liver has reached its limit while the kidney threshold for sugar excretion is at a high

¹ *Indian Journal of Medical Research*, vol. iv, p. 1, and vol. vi, pp. 485 and 503. Observations on the Sugar of the Blood and the Sugar in the Urine in Varying Conditions of Health in the Bengali. By Lieut.-Colonel D. McCay, M.D., M.R.C.P. (Lond.), I.M.S., Professor of Physiology, Medical College, Calcutta; Assistant Surgeon Rai Bahadur Satish Chandra Banerjee, L.M.S., Assistant Professor of Physiology; Assistant Surgeons Lal Mohan Ghosal, L.M.S., Madan Mohan Dutta, L.M.S., and Charnbrata Roy, M.B., B.Sc., Demonstrator of Physiology, Medical Department, Medical College, Calcutta. The paper is a volume entitled *Diabetes in India*, published by . . . Co.

level; that in the second class the glycogenic function of the liver is more efficient but the kidney threshold is lower; and that in the third class the glycogenic function of the liver is normal but the kidney threshold is low.

It appears that in general the plane of carbohydrate metabolism is higher in the Bengali than in the European, since the lean hard-working coolie, though his average blood sugar is high, has only just sufficient for his daily requirements. Little or no fat is deposited in his tissues and the liver is never saturated with glycogen. Each individual has narrow personal limits within which the sugar concentration of the blood varies, but in different individuals the limit may vary widely. There are similar individual variations in the kidney threshold, and they are independent of the glycogenic powers of the liver or the oxidative processes of the tissues.

The authors call particular attention to some observations showing that the level of concentration of sugar in the blood may, within a wide range, be independent of the kidney threshold. Thus glycosurias may be met with whose threshold is high—the usual condition in the fat, overfed classes; in others, again, it is low, and some individuals have lost the power of storing sugar and of converting sugar into fat. Again, there are individuals in whom the permeability of the kidney to sugar is excessive owing to oxaluria, gout, or stone. In the healthy person, in potential diabetics, and in actual diabetics alike the ingestion of glucose is always followed by an increase of the sugar in the urine, whether the blood sugar increases or not. Finally, kidney disease may prevent glycosuria even when marked hyperglycaemia up to 0.86 is present. Such individuals are hyperglycaemics without glycosuria; they seem to go in jeopardy of sudden death from coma.

In discussing the onset and march of glycosuria, the authors find it impossible to resist the conclusion that in otherwise healthy individuals permanent glycosuria can be caused and maintained by overfeeding with carbohydrates. They do not believe that this only occurs in individuals who are really not absolutely healthy, but rather that even the healthiest show some degree of failure to use carbohydrates. In other words, their view is that the normal human organism is inherently diabetic.

Having observed that a tendency to fat deposition appeared to represent a pre-glycosuric stage, they decided to estimate the fat in the blood in these cases and note the effects of administration of glucose. Their observations lead them to believe that the fat formation goes hand in hand with, and is due to, hyperglycaemia. So long as fat formation can keep pace with the hyperglycaemia glycosuria is avoided. When the fat formation is overtaxed, intermittent glycosuria supervenes, and later, when the fat-forming powers fail altogether, the glycosuria becomes permanent. Then the patients begin to waste. At this point the authors see another pathological factor intervening. Though the exact nature of this pathological factor remains unknown, they believe it to be related to a gastro-duodenitis which leads to some damage to the pancreas, whose internal secretion is thereby impaired.

The problem of coma as a cause of death in diabetes has been carefully studied. In the Indian type of coma signs of acidosis are usually wanting or are only slight in degree, and the terminal coma is almost invariably uraemic and accompanied by retention of nitrogenous waste products. The authors believe that in this respect coma as seen in Indian diabetics differs from that met with in Europe. But here they are in remarkable agreement with the views of Marcel Labbé, who considers that in the severest forms of diabetes some derangement of protein metabolism is added to the carbohydrate disturbance. This coincidence of opinion is worthy of note. It opens up the important question whether there is indeed a special coma peculiar to diabetes.

In treatment a plan of a severely restricted diet, with occasionally total carbohydrate starvation, was adopted. Complete starvation, as introduced by Guelpa in 1910 and popularized by Allen, was not resorted to. When the urine had been rendered sugar-free and the blood sugar level had fallen, a process of gradual re-education to tolerance of carbohydrates was commenced. The mi-type of glycosuria prevailing in India gave flattering results. In the few cases where nitrogenous metabolism was disturbed the treatment did not avert a fatal termination; these were doubtless instances of that variety which Marcel Labbé has said impressively, "Nothing cures them."

Lieut.-Colonel McCay and his "team" are to be congratulated upon a very valuable contribution to our knowledge of the troubles associated with disturbance of carbohydrate metabolism, commonly called diabetes.

INSANITY AND RESPONSIBILITY FOR CRIME.

THE trial of Ronald True for the murder of Oli Young, and his unsuccessful appeal against conviction provide material of considerable medico-legal interest and importance, owing to the extension of the McNaughten rules which was laid before the jury by Mr. Justice McCardie, and the full discussions which took place both courts on the principles governing the relation between insanity and responsibility for crime.

Since 1843 the courts, where the defence of insanity is raised, have been guided by the ruling, the operative words of which are as follows: "To establish a defence on the grounds of insanity it must be clearly proved that at the time of committing the act the accused was labouring under such a defect of reason from disease of the mind as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know he was doing what was wrong." It has long been recognized that this definition does not cover all the cases in which the general sense of the community would hold that the accused should not be considered responsible, since it is well known that a person may be admittedly insane and yet capable of appreciating the nature and quality of his acts and of distinguishing between right and wrong. A good instance was afforded by the lunatic Ware, who, after killing a fellow inmate in the asylum with an iron bar, climbed on to a roof threatened everyone who approached him, and refused to come down until he was promised freedom from punishment. In this case there was of course no question as to the presence of insanity, but alienists hold that there are other persons equally to be regarded as irresponsible owing to disease of the mind, although they do not present to the layman symptoms conclusive of insanity. In some cases of early general paralysis of the insane, epileptic insanity, paranoia, and even senile dementia, there may be impairment of the power of self-control leading to the commission of crimes before delusions or other definite signs of insanity are manifested. The courts, however, are not reasonably, very chary of admitting irresponsibility in these cases, and thus there may arise a divergence between legal and medical opinion as to the conditions which should be fulfilled before a defence of insanity can be accepted.

With the object of arriving at a standpoint which should be acceptable to both lawyers and medical men the British Medical Association appointed a special committee in 1913 to consider the state of the law with regard to legal responsibility for crime, and the Council, the Incorporated Law Society, the Medical Psychological Association, and the Medico-Legal Society each nominated two members of this committee.

report of the committee, which was approved by the Annual Representative Meeting in 1915, recommended the following principle: "No act is a crime if the person who does it is at the time when it is done prevented, either by defective mental power or by any disease affecting his mind, (a) from knowing and appreciating the nature and quality of his act or the circumstances in which it is done; or (b) from knowing and appreciating that the act is wrong; or (c) from controlling his own conduct unless the absence of control has been produced by his own default." It might have been hoped that a recommendation made by a committee so representative of all views would have been followed by legislative or other authoritative action, but the country was occupied with other things, and until this trial the position has remained substantially what it was when the McNaughton rules were first promulgated.

The importance of the True trial comes from the fact that Mr. Justice McCardie definitely conceded the principle for which medical opinion has so long been contending. In his charge to the jury he said: "Even if the prisoner knew the physical nature of the act and that it was morally wrong and punishable by law, yet was by mental disease deprived of the power to control his actions, then the verdict should be 'Guilty, but insane.'" In the Court of Criminal Appeal the Lord Chief Justice said that this was an extension of the McNaughton rules. Counsel for the defence had cited a number of cases in which he submitted that the old rigour of the rule had in fact been relaxed, but the Lord Chief Justice did not consider that proposition to be accurate, and said that in none of these cases had the proposed extension of the rule been acted upon and approved. No further opinion upon Mr. Justice McCardie's action was expressed by the Court of Appeal.

As regards the actual facts of the case, we do not propose to question the justice of the verdict or the upholding of that verdict by the Court of Appeal. Sir Henry Curtis Bennett for the defence claimed that as four doctors had expressed the opinion that True was insane, and the prosecution had not called any medical evidence to rebut these opinions, the jury should have been bound by the medical evidence. It is difficult, however, to accept this view. The medical opinion is only part of the evidence which is placed before the jury, and the jury should arrive at their verdict from a consideration of the whole case. In the last resort the civil authority must be supreme. In non-criminal questions connected with insanity the lay authority exercises the final jurisdiction. The judicial authority under the Lunacy Acts may, and not infrequently does, refuse to sanction the detention of a person in the face of two medical certificates that he is insane. Far less, then, would the medical profession wish, or the community agree, that in criminal cases the final word should be with the medical witness.

Apart from such considerations, we cannot agree that on its merits the medical evidence, while deserving of due weight, was such as to justify sweeping all other considerations aside. True appears to have formed a deliberate intention to commit the crime; he was in want of money at the time, as shown by the fact that he had given a worthless cheque and had left hotels without paying his bills; he robbed the unfortunate woman of her jewellery; he made some effort to conceal the crime by placing pillows in the bed so as to suggest that a person was still sleeping there; he went away and changed his clothes; he invented a story of having left some man quarrelling with the woman; and he took other steps which clearly showed that he appreciated his act and the consequences to him which might ensue. The crime cannot be said to have been the outcome of an uncontrollable impulse in an ill-balanced mind, which

the Subcommittee of the British Medical Association sought to provide for when it proposed the addition to the McNaughton rule. Too much importance should not, we think, be attached to the evidences of insanity which medical witnesses noticed after True had been arrested, for a prisoner under a charge of murder is not likely to be in a normal frame of mind, and it is the state of his mind at the time he committed the act which has to be determined. Similarly, in regard to the fact that in his previous life True seems to have been mentally unstable at times could at the most only have strengthened any evidence of insanity at the time when he committed the crime. There are forms of insanity in which the individual may have long lucid intervals, or even apparently quite recover. A manic depressive, for instance, may, after an attack, be, so far as can be judged, perfectly well for years before any symptoms recur. We could not subscribe to the view that if a man has been once certified he is to be held irresponsible for crime for the rest of his life. His acts must be judged on their merits, and if in themselves they show evidence of insanity the fact of the previous attack undoubtedly strengthens the view that he was insane. If, however, he commits a cold-blooded murder with deliberate forethought and motive, and takes steps that a sane man would take to avoid the consequences, the finding of the jury, tested by the Court of Appeal, must be accepted as doing justice in the case.

BOMBAY SCHOOL OF TROPICAL MEDICINE:

A BROKEN UNDERTAKING.

We learn from India that the Government of Bombay has declined to proceed with the project for establishing a School of Tropical Medicine at Bombay. The news is not a little surprising, for the Government of Bombay had very definitely expressed its intention to establish the school, and Sir Dorab Tata had promised to contribute a lakh of rupees a year towards the expenditure which was to be incurred. The Bombay School of Tropical Medicine was to have been opened on April 1st last, and all arrangements were made for this purpose. It was only at the last moment that the Bombay Government determined to cut out of the budget the whole sum allotted to the school, and issued orders that the scheme should not be proceeded with. In consequence Sir Dorab Tata has withdrawn his offer, which was contingent on the Government founding a school of tropical medicine at Bombay. As will be seen, matters had gone very far before the Government of Bombay repudiated the undertaking it had given. They had gone even further than we have so far indicated, for rather more than a year ago the Royal Society was asked to select professors for the chairs of clinical medicine and therapy and of protozoology in the school. The Royal Society, acting through its Tropical Diseases Committee, issued advertisements widely—in this country, in the Dominions, and in America. From among the applicants it selected two, one for each chair. The protozoologist selected was an American, but he, we understand, subsequently, on private grounds, withdrew his acceptance. The successful applicant for the other chair, an Australian (Professor N. Hamilton Fairley), resigned his appointment in Australia to become Tata Professor of Clinical Medicine in the Bombay School. The Government of Bombay has now given him notice that it will dispense with his services on October 31st. The situation thus brought about is obviously most unsatisfactory, and the matter cannot be allowed to rest where it is. When the Royal Society acts for the Indian Government and invites applications for positions on definite terms, the candidates selected assume that a written contract is superfluous. Clearly the Royal Society has been placed in a very false position. At the request of the Government of India it undertook to select suitable persons to occupy the two chairs. With the authority of the Government of Bombay the Royal Society, through its Committee, issued advertisements inviting candidates

to come forward and stating the terms and conditions of the appointment, which was to be in each case for a term of five years in the first instance, "but may be extended by the Government." It is now left in the lurch by the Government of Bombay, which professes to find that it has miscalculated its resources, and is not in a financial position to carry out its bargain. The Royal Society will, we feel sure, have the support of public opinion in any action it may take, and the medical profession in particular will be anxious to see that justice is done to Professor Fairley, if not by the Government of Bombay, then by the Government of India, which cannot absolve itself from responsibility for the acts of the provincial government. We understand that a new central research institute for India may shortly be established, probably at Delhi; this may afford the Government of India a way out of the false position in which it has been placed by the Government of Bombay.

THE ASYLUM SYSTEM.

WE have received a copy of correspondence which has passed between Sir Alfred Mond, M.P., Minister of Health, and Lord Henry Cavendish-Bentinck, M.P., on the subject of a letter of appeal circulated by the National Council for Lunacy Reform with regard to the conditions alleged to exist in lunatic asylums. In that appeal the statement was made that "the Minister of Health has admitted that under present conditions lunacy is treated as a crime rather than as a disease." To this statement Sir Alfred Mond takes exception, and in a letter to Lord Cavendish-Bentinck, who is honorary treasurer of the National Council, he points out that in the speech from which his remarks were quoted his actual statement was "that there was no doubt that the general public thought that we treated lunatics as if lunacy were still looked upon as a crime and not a disease." In reply to this letter Lord Cavendish-Bentinck accepts Sir Alfred Mond's denial of the views attributed to him and unreservedly withdraws the statement to which exception had been taken, but he urges the appointment of a Royal Commission to inquire into a system about which he feels the public mind is so seriously disturbed. It often happens that remarks made in the course of a speech are misunderstood by those to whom it is addressed, and when this occurs, as in the present instance, the erroneous impression can subsequently be corrected by the speaker, although it may be difficult to catch it up. It is otherwise, however, with certain criticisms of asylums which are included in the letter of appeal which the National Council for Lunacy Reform has caused to be circulated. The letter is written in such a way that the public would inevitably gather from it that nothing whatever is done in the way of curative treatment for the patients in asylums. An impression of this kind cannot be corrected as can an erroneous quotation. The whole letter, though referring to a system, implicitly casts more serious reflections on the doctors and nurses who are responsible for the care, nursing, and treatment of the insane. However much reforms may be needed in the asylum work we think it regrettable that the view should be circulated that nothing is done for the cure of the insane and that there is an "almost entire lack of curative hospital conditions" in asylums, when in a large number of these institutions every effort is made to restore the patients to health and send them again into the outside world.

THE "DENTISTS REGISTER."

Persons who desire to obtain registration or entry under one of the various sections of the Dentists Act, 1921, should make application as quickly as possible. The Act is dated July 28th, 1921, and the fourth subparagraph of Section 1, which prohibits the practice of dentistry by unregistered persons, directs that the section of the Act shall come into operation on the expiration of one year from the commencement of the Act. The application must be made within the interim period allowed. The expression "interim period" is defined in Section 14 of the Act to mean the period between

the commencement of the Act and the date on which its provisions prohibiting the practice of dentistry by unregistered persons come into operation. On the average an interval of about two months is found necessary between the time an application is received and the registration effected, and a person who is not registered when the Act comes into force, whether he has made application or not, will come under the operation of the section prohibiting practice. There is, however, power by an Order in Council to extend the interim period for a further period not exceeding two years, but the Minister of Health stated recently in the House of Commons that though the question of such extension was under consideration no statement could at present be made. Further, it is to be noted that Section 14 gives the Dental Board power, on application made at any time within two years of the date of its coming into operation, to allow a person to register if the Board is satisfied that there were valid reasons for the failure to make an application before that date. It is, however, obviously desirable that all persons who desire to be registered should regularize their position at once by sending an application to the Registrar of the Dental Board of the United Kingdom, 44, Hallam Street, London, W.1. We understand that some uncertainty has been felt as to the position of a person already on the *Dentists Register*; it has been asked whether he must register again under the Act, and whether he will henceforth have to pay an annual registration fee of £5. We are informed that any person registered on or before July 27th, 1921, will not be required to register again or to pay an annual fee. Any person who registered on or after July 28th, 1921, will, if he desires his name to be retained on the *Register*, be required to pay an annual fee, which at present is fixed at £5.

FATAL BOTULISM.

HITHERTO this country has escaped any serious prevalence of the form of food poisoning to which the term "botulism" has been applied, but it continues to occur in other countries, and a considerable number of outbreaks have been reported in the United States. The symptoms are sufficiently well marked to make it improbable that the condition would be overlooked; in fact, it presents so close a resemblance to lethargic encephalitis that when the disease first appeared in this country some of the earlier cases were believed to be examples of botulism. The organism has been isolated and an antitoxin prepared, but, so far, little benefit appears to have been derived from its administration in man, although animal experiments have encouraged perseverance in its use. The name given to the disease is due to the fact that the first cases described were observed in Germany, and were associated with the eating of sausages (*botulus*, a sausage). The death rate in true botulism appears to be high, and death may ensue within a few days of eating the contaminated food. An example of the outbreaks which occur in the United States is afforded by one observed by Whiteman and Wilkinson in Cambridge, Idaho, and described in the *Journal of the American Medical Association* for April 29th, 1922 (p. 1278). Seven members of a family, with two guests, shared a meal which included, among other food, greens which had been tinned at home. Of the nine persons who partook of this meal, eight became ill with botulism and six of the eight died; only one of the nine was unaffected. The symptoms were closely alike in every case, but two types of illness were noted—one in which the vomiting was severe and the duration of illness shorter, and one in which prostration was a predominating symptom. Descriptions of two of the most typical cases are given; the early symptoms included dizziness, blurring of vision, and unsteady gait, followed by vomiting; later blepharoptosis, parasthesia in the extremities, weakness of the arm, leg, and especially neck muscles, dyspnoea, dysphagia, and aphonia were noted in all of the fatal cases. Dilatation of the pupils with sluggishness of the light reflex and Babinski's sign were present, and the knee-jerk were exaggerated. Post-mortem examinations were refused by the family. Two months after the onset of the symptom

one of the surviving patients had fully recovered, but the other was not strong enough to mount a horse unaided. The treatment of these cases was expectant. Ice was sucked when swallowing became difficult, and physiological saline solution was administered subcutaneously and by drop method into the rectum. The survivors were freely purged with half an ounce of magnesium sulphate four times daily; and a mixture of potassium permanganate 1 grain, sodium bicarbonate 1 drachm, and water 6 oz. was given internally four times daily. No specimen of the suspected food or the containers could be obtained for examination. The surviving members of the party stated that they ate freely of all the foods except the tinned greens, and gave as their reason for refusing this that it had a peculiar musty smell and an unpleasant but indescribable taste. Seven tins of food, prepared at the same time and under the same conditions as the suspected greens, were examined, and five showed evidence of decomposition, although *B. botulinus* was not found on bacteriological examination.

THE TRAINING OF THE BLIND.

THE seventh report of St. Dunstan's Hostel and After-Care Organization for Blinded Sailors and Soldiers shows that last year 406 men were receiving training in the workshops and classrooms of St. Dunstan's. In January of this year 15 new cases had to be admitted, so that the work of training blind sailors and soldiers is not ended, and the need for support is still very real. With the completion of the training of a blind man a new problem is presented, that of setting him up in the work for which he has been trained. This work, what is commonly known as "after-care," engages the activities of St. Dunstan's and represents a considerable business, and one that needs the greatest tact and thought on the part of the administrators. The best trained blind man is at a disadvantage in open competition with his sighted fellow worker, so that the careful placing of these blind men where they may best follow their employment, and the tactful observation of them during the earlier years of their activities, present a complex problem. Its complexity is increased by the difficulties in the way of getting suitable shops, houses, or other premises, owing to the present shortage; St. Dunstan's has been compelled to become a landlord on a considerable scale by securing properties in which to establish its men; they are leased or sold on a hire-purchase scheme on reasonable terms. It has nearly 300 men on its rent roll, and 120 are expected to need settlement during the next year. St. Dunstan's buys material wholesale for the settled men, and £18,000 worth of material was so bought last year. It sells the output of the men where necessary, and sold £12,000 worth last year. When so many men are unemployed St. Dunstan's feels a legitimate pride in the fact that there is not a single trained stenographer or telephone operator who has left and is out of work. The report gives a number of extracts from letters received from men settled by St. Dunstan's, and throughout there is a tone of satisfaction in useful work, which is the best testimony to the value of this voluntary effort. It is well worthy of the support of the generous.

INCOME TAX AND LOCUMTENENTS.

FROM time to time we have received inquiries as to whether a medical practitioner was entitled to treat the cost of the services of a locumtenent as a proper deduction for income tax purposes. As a matter of strict legality the point is not free from doubt, and local inspectors have often urged that a locumtenent's fees are part of the total cost of a practitioner's holiday rather than of his professional work, so that in very many cases such payments were allowed only where their necessity arose through the physical unfitness of the practitioner. This distinction has never appealed to us as well founded; prevention is not only "better" but less costly than "cure," and assuming that a practitioner whose health has given way through overwork can claim to deduct a locumtenent's fees during his enforced absence from professional work, it would seem to follow that the same grounds would justify allowance of the expenses where necessary to obtain

that holiday which will obviate a breakdown. It is therefore satisfactory to learn that the Board of Inland Revenue is now prepared to agree that expenses incurred by a medical practitioner in maintaining his practice while he takes his annual holiday can properly be deducted in computing his liability under Schedule D. Such expenses, we may perhaps add, would cover not only the cash payment made to the locumtenent, but also the cost of his board and lodging.

POST-GRADUATE COURSE IN PAEDIATRICS.

THE Fellowship of Medicine and Post-Graduate Medical Association has arranged a post-graduate course on diseases of children, to be held from Monday, July 3rd, to Saturday, July 8th. Clinical demonstrations in the various departments will be given at the following hospitals, which have agreed to take part: East London Hospital for Children, Paddington Green Hospital for Children, Victoria Hospital for Children, Queen's Hospital for Children, St. Marylebone General Dispensary. The syllabus for what is aptly called "Children's Hospital Week" will be ready in a few days' time, and copies may be had on application to the Secretary to the Fellowship of Medicine, 1, Wimpole Street, London, W.1. Should a sufficient number of entries be received it is proposed to repeat the short course in general medicine, recently held, during July and August; the dates will be announced shortly. The *Bulletin* for June giving general information on post-graduate work in London is available and copies may be obtained from the Fellowship of Medicine. The next post-graduate lecture at the Royal Society of Medicine will be delivered by Sir William Hale-White on "The clinical symptoms of *coli* infection of the urine," on Tuesday, June 13th, at 5 o'clock.

THE next social evening of the Royal Society of Medicine will be held at the house of the society, 1, Wimpole Street, W., on Wednesday, June 14th. The President and Lady Bland-Sutton will hold a reception at 8.30 p.m., and Dr. T. M. Legge, C.B.E., will deliver an illustrated address on Industry and Art at 9 p.m.

General Medical Council.

NOTES.

Medical and Dental Education.—The one hundred and fifteenth session of the General Medical Council, which concluded on May 29th, has been the longest of recent years. The President's address was reproduced in full in the SUPPLEMENT for last week, and a report of the other proceedings is continued this week. The length of the session was due not so much to the disciplinary cases, though these perhaps exceeded the average in number and complexity, but to the simultaneous completion of several educational and examinational matters which have been occupying the committees. Among these has been the revision of the curriculum in medicine and in dentistry. At previous sessions what might be called second reading debates have taken place, and on this occasion the matter reached report stage. The question of the revision of the medical curriculum arose out of a desire that the preventive aspects of medicine might be more strongly emphasized. It was first approached in 1918, largely, we believe, at the instance of Dr. McVail. The movement for the revision of the dental curriculum was started in the Council in 1914 by Sir Arthur Newsholme, who is no longer a member. It had its origin in the public belief, fostered by unregistered dentists, and not altogether denied by the registered, that the number of recognized dentists was insufficient. In both cases the inquiry went beyond what was originally intended, and the result has been the revision of the whole of the recommendations of the Council on the subject of the curriculum, both for medicine and dentistry. The new regulations will come into effect on January 1st, 1923.

Demonstrations on the Living.—The Education Committee, in connexion with the practical applications of the revised curriculum, brought up a proposal that the teaching of anatomy and physiology should include, as a regular part of the course, a demonstration of structure and function on the

living body. Thereupon Sir Isambard Owen asked what precisely was intended by this phrase, which, he thought, might give rise to misconceptions on the part of the public, and Sir Sydney Russell-Walls confessed that when he first read the passage he thought it related to animal experiments. Sir Donald MacAlister, however, expressed the belief that the man in the street would understand that it was better to demonstrate the action of a muscle on the living rather than on the dead subject. He said that the matter arose because several of the subcommittees which had been considering the subject wished to emphasize the study of the living human body throughout the course of anatomy, and, some of them, throughout physiology also especially in relation to the organs of sense. With a view to removing any possible misunderstanding, an amendment inserting the word "human" was agreed to. The idea, of course, is not new. Many, many years ago the crossing sweeper used to earn a welcome half-crown by allowing himself to be the subject on which students attending the course of practical surgery marked out in blue pencil the incision they would make for some operation upon which the lecturer was discoursing: nevertheless we make no doubt that it will be assumed in quarters where no argument convinces that what is now intended is human vivisection.

Regulations for the D.P.H.—It is a pity that the greater part of the last meeting of the Council was occupied with relatively a minor matter—the method of assessing marks at examinations—so that the report of the Public Health Committee on the new rules for the diploma, upon which a long debate had been expected, had to be introduced and approved within an hour. But there was opportunity for one of Sir George Newman's interesting speeches, in which he always raises a debate to a high level. He did not conceal his satisfaction in the fact that the new rules for obtaining the diploma in public health will virtually exclude all those who do not intend to make the public health service a career, but desire to wear the diploma merely as an ornament. To the objection that they closed the door upon the general practitioner, he replied that it must not be forgotten that the Council by tightening up the general curriculum was aiming to make the general practitioner of the future as well equipped in respect to preventive medicine as was at one time the holder of the old D.P.H. The rules, which gave rise to a long discussion at the last session, appeared to receive general approval on this occasion, and only one objection was expressed, and even this did not command a majority. This was an objection to the interval of two years which is to elapse between the attainment of a registrable qualification and the final examination for the public health diploma.

Midwifery in Indian Universities.—An interesting matter which did not come before the Council, but was considered by the Executive Committee in the course of the session, was the inspection of midwifery teaching in Indian universities. Dr. Norman Walker, who has lately been visiting India, reported that he discovered a number of grievances at the universities with regard to the action of the Council—as, for example, that the communications of the Council were addressed to "the Indian universities," thus grouping all, good and bad, together; that the tone of the communications was peremptory; and that it was not recognized that the methods of teaching practical midwifery in Madras, Bombay, and Calcutta were superior to those of at least some of the schools at home. Dr. Norman Walker dealt with all these matters diplomatically, and his recommendations, which the Executive Committee has adopted, are that the degree of M.B., B.S. of the University of Madras should continue to be recognized, and that the similar degree of Bombay, Calcutta, the University of the Punjab (Lahore), and Lucknow should continue to be recognized until June 30th next, and thereafter year by year upon the receipt of a satisfactory report from an official inspector approved by the Council, and in the case of the last two universities of a statement also by the dean of the Faculty of Medicine containing the nominal roll of the graduates of the year, and a certificate that each of them has fulfilled the Council's recommendations. Dr. Walker believes that it will be possible for each of the Indian universities to show that its regulations for the teaching of practical midwifery are sufficiently in accordance with the recommendations of the Council to enable the Council to recognize their certificates. He has suggested to the Government of India that it should propose to the General Medical Council that the services of Colonel R. A. Needham, Deputy Director-General I.M.S., who accompanied him throughout his tour, should be accepted as those of the approved inspector.

Disciplinary Cases.—The hearing of disciplinary cases by the General Medical Council is usually a pitiable business—the story of careers ruined, at any rate for the time, by some weakness of character which has led the respondent into a course of conduct he quickly learns to regret. Usually, by the time he appears in the Council Chamber the respondent is contrite and promises amendment. This was not the attitude of Dr. Kynaston. As may be gathered from the report of the proceedings in his case published in the SUPPLEMENT, his attitude was confident, and though his cross-examination of the few witnesses called was not perhaps very effective, the examination and re-examination of himself was conducted in a vigorous manner. Dr. Kynaston some years before the war retired from the R.A.M.C. with the rank of major, but was re-employed during the war with the rank of lieutenant-colonel. He has satisfied himself that enlarged tonsils and adenoids can be efficiently treated without operation and has condemned the frequency with which such operations are now performed. He is, of course, entitled to hold these opinions, but exception has been taken to the manner of their presentation. Dr. Kynaston stated that he had sent his resignation from the Medical Register to the Council, but the President pointed out to him that he had no power to resign from the Medical Register. The charge brought against him by the Medical Defence Union was heard by the Council. It is set out in full in the report in the SUPPLEMENT, and, as will be seen, it resolved itself into an accusation that he had sought to attract to himself patients for his own gain by means of advertising. The Council, after deliberating on the case *in camera*, directed the Registrar to erase Dr. Kynaston's name from the Medical Register, and the proceedings in the case closed by Dr. Kynaston expressing his thanks to the Council. So the incident ended, but we shall be doing, we imagine, no wrong to Dr. Kynaston if we assume that we have not heard the last of his campaign which at various times has carried him into the lay press. To another case, that of Dr. Robert Bell, the attention of the Council had been called by a committee of practitioners in Warrington. The charge, as will be seen from the full report in the SUPPLEMENT, was that Dr. Bell had for a period of nine months prescribed for and treated a woman suffering from inoperable cancer without ever having seen or examined her, the prescribing and treatment being carried on by means of correspondence with the patient's husband, a person without medical skill or knowledge. From the opening statement of the solicitor for the Council it appeared that when notified of the complaint in due course Dr. Bell took a very high hand and threatened the Registrar with an action for libel. In his evidence before the Council he maintained that the report of a medical man that a case was incurable was a sufficient report, and that by his method of treatment such cases were curable in many instances. Lord Tenterden, chairman of the Batterssea General (Antivivisection) Hospital, was called as a witness for the defence, and stated that Dr. Bell had succeeded in cases where others had failed to cure. It will be seen that the Council found the facts alleged proved, and through the President informed Dr. Bell that it took a grave view of the conduct of a practitioner who for gain prescribes for and treats by correspondence, without having seen or examined the patient, without medical evidence as to the actual nature of her complaint, and without securing medical assistance and co-operation in the actual treatment. It, however, postponed taking any action until May, 1923, when the respondent should be prepared to satisfy the Council that in the interval he had been without reproach in respect of such methods of practice. The Council through its President thanked the Warrington practitioners who had called attention to the case. In another case, that of a practitioner who had been convicted at the Central Criminal Court last September of having unlawfully administered to a woman certain poisons and noxious things with intent to procure her miscarriage, and sentenced to a term of imprisonment, the conviction being afterwards confirmed by the Court of Criminal Appeal, a strongly worded application for leniency was made by the respondent's counsel, Sir Edward Marshall Hall, K.C. Among other points it was stated that a petition to the Council with 5,000 signatures had been received from one of the districts in which the respondent had practised. The Council, however, decided to erase the respondent's name from the Medical Register.

whereby there would be a greater exchange of duties between infirmaries and ordinary hospitals. He also hoped it would be found possible to give a place upon a central commission sitting in London to some representative of the Voluntary Hospitals Committees.

The Earl of Onslow, in reply, said that it was proposed to constitute in all sixty-two committees throughout England, Scotland, and Wales; fifty-two were already formed and were actually working, and six would very soon be ready. In two cases—one in England, the other in Scotland—no committees were to be formed because the local conditions were such that it was unnecessary; there was only one hospital in each county. In two other cases no decision had been reached. Some of these committees had been in existence for a considerable time, but the majority had only begun to work within the last few months. Each had been asked to report the actual situation in the area, and many had sent in valuable reports, though sufficient information had not been given about all the small areas to afford a comprehensive survey of an authoritative nature for the country. Very good reports had come from Devon, Cornwall, Warwickshire, Bristol, Derbyshire, Wiltshire, Sheffield, and some other districts. Touching Lord Malmesbury's suggestion that local committees should be represented on the Commission, the Earl of Onslow recalled that the Commission was formed on the proposals of Lord Cave's Committee, with the addition of a representative for Wales. Of the representatives on the Commission, five were appointed by the Ministry of Health, one by the Secretary for Scotland, and seven by various bodies connected with the hospitals, the Royal Colleges of Physicians and of Surgeons, the Order of St. John and the British Red Cross Society, the British Hospitals Association, the British Medical Association (which had two representatives, one for England and one for Scotland), and King Edward's Fund. That Fund having accepted the position of Voluntary Hospitals Committee for London, the metropolitan area was directly represented on the Commission. A conference of members of all local committees would meet in London on July 18th and 19th, when a full discussion of the subject would be possible. The views of the members of local committees as to whether the Commission would be strengthened and on how the representation might be made would be of great value. He thought it important to avoid making the Commission so large as to be unwieldy, but that did not appear to be a necessary corollary to the proposal. Of the original Government grant of £500,000, the Commission had spent £103,450 in London and £39,288 in the provinces—a total of £142,738. The reason that London had received so considerable a share so soon was that as King Edward's Fund was acting as the Committee reports were more speedily available. The London grants so far had been almost entirely emergency grants—that is to say, grants to hospitals who had exhausted their realizable assets. The grants, therefore, were mostly given before the annual accounts were made up. They had enabled beds to be reopened, and had prevented the threatened closure of others. The Commission decided as a general principle not to make grants in excess of half the deficit on the ordinary maintenance expenditure for the year ended December 31st, 1921, and those grants were to be made £ for £ against new money received or in sight. This term, "money received or in sight," was difficult to define; the Commission had explained it to the best of its ability, and was issuing a circular dealing with the matter at length. The Government grant of £500,000 was based on the estimate that the total deficit on maintenance account for 1921 would be approximately the same as that in 1920—namely, £1,000,000 for the whole country. But it was very gratifying to note that the reports so far almost all showed that in all probability the 1921 deficit would be considerably less than the 1920 deficit. The 1920 deficit in London amounted to £463,000, and the estimate—it was only an estimate, yet fairly accurate—was that the deficit for 1921 would be about £140,000 less. Similar figures came from other localities—hence the great hope of a considerable lessening in deficit. That being so he hoped that it might be possible to give some assistance in respect of accumulated deficits, but on that point nothing definite could be said until a complete estimate of the amount of the deficits for 1921 throughout the whole country was available. He appreciated the difficulty hospitals had found in presenting their claims, because they did not make up their accounts until the beginning of the year, but he hoped that claims would be soon completed so as to enable the distribution to proceed. An arrangement was made last year with approved societies for payments to hospitals in respect of their members. The Commission had had representations from the societies that the claims were not coming in from the hospitals. The Commission trusted that all hospitals would ask any patient who came to them whether they belonged to a society, and, if so, whether it was one of those societies upon which the hospital could make a claim,

and that the claims would be proceeded with as soon as possible. Though the position of the hospitals was improving, the deficits were still very formidable, and no effort must be relaxed to put the hospitals on their pre-war footing. Co-operation was the only way—co-operation to reduce expenditure, to increase income, and to prevent overlapping and waste. Dealing next with schemes for extension which certain hospitals had proposed, he said that they must all be very carefully examined, and it must be shown that income was sufficient to meet any increased expenses of maintenance the extension would necessitate. He did not say their extension should not be undertaken, because in certain circumstances extension might be desirable, because sometimes capital expenditure was true economy. As to the possibility of utilizing Poor Law infirmaries, he said that co-operation had been found possible in certain places, and instanced Paddington and Wolverhampton; but Poor Law infirmaries were the property of the ratepayers and could not be touched unless the guardians were willing to co-operate. The local committees would be able to get an idea of what was required, and if the guardians were willing might form a scheme for utilizing vacant beds in the infirmaries. Many members of boards of guardians were members of voluntary hospital committees, and therefore co-operation should not prove difficult. In conclusion, Lord Onslow said that it appeared that income on the whole was well maintained, although in a few cases there had been a falling off, especially in areas which had experienced strikes. Moreover, expenditure was falling. The cost of food—a very large item in hospital expenditure—was coming down considerably, but drugs and dressings remained at a rather high figure. He referred to the success of the scheme for mass contribution illustrated in the Sheffield area, and said it was important for local committees to organize such schemes wherever possible. Until the Oxford scheme was developed the mass contributions were mainly confined to northern England, and its success at Oxford was worthy of note—no less than £16,000 had been raised there last year by these means. Hampshire had, he believed, already made a great success of the scheme. In Manchester there was an arrangement with the Hospital Saturday Fund for a combined collection and the organization of massed contributions. He was glad to congratulate London on its collection of the previous day.

In reply to further questions, Lord Onslow said he trusted there would be considerably more funds for the provinces. If further claims were sent in by local committees the Commission would be glad to consider them.

Drugs for Pauper Patients.—Mr. R. Young asked, on May 25th, whether under the National Insurance Scheme necessary medicines beyond a certain price could not be prescribed for serious illnesses—for example, gastro-enteritis—and that therefore some pauper doctors advised pauper patients to become private patients. Sir A. Mond replied that insurance practitioners were required to order such drugs and appliances as were necessary without limit of price subject to certain precautions against needlessly expensive prescriptions. He should take severe disciplinary action in case of proved failure to carry out that duty. Mr. Young asked if Sir Alfred Mond knew that doctors called before the responsible committees had to give explanations of their expenditure and were reprimanded on occasions. Sir A. Mond did not doubt that course was taken. He would pursue what disciplinary action was necessary.

The Milk Supply.—Sir A. Mond in answer to Mr. Doyle, on May 24th, said he was advised that the milk supply found in Newcastle were probal in other parts of the country. He was legislation on the subject of milk.

Outside Staff of Health Ministry.—On a question by Captain Elliot, on May 23rd, as to the regrading of the outdoor staff of the Ministry of Health, and the proportion of higher posts for men and women, Sir Alfred Mond said that women inspectors are engaged to inspect trades where women are mainly employed, and in inquiries as to the benefits of insured women. The proportion of higher to lower posts is fixed with reference to the requirements of the work, which is more limited in the case of women. The proportion is more favourable in the case of women.

Child Murder (Trial) Bill.—Lord Parmoor's Bill (subjected to severely definitive redrafting amendments) was passed through Committee in the Upper House on May 25th. The object of the measure is to allow of the reduction of an offence from "murder" to "infanticide" in cases where a mother has intentionally caused the death of her newly born infant at a time when she has not fully recovered from giving childbirth and when the balance of her mind is disturbed. The Lord Chancellor said it was not proposed to alter the law, so that the ordinary physical suffering of a woman in childbirth, aggravated by such additional mental suffering as a woman who had an illegitimate child was supposed to entertain, should alone constitute the ground for reducing responsibility. Exceptional derangement and disturbance must be established. The definition was a matter of difficulty, and would be subject to further consideration before the Report stage. It was the desire of the Government that the bill should become law, and no reasonable opportunity of getting it passed would be neglected.

England and Wales.

PRESENTATION TO DR. HERBERT JONES.

On the conclusion of the session of the Hereford City Parliament Dr. Herbert Jones was presented with his portrait in oils, bearing the following inscription: "Presented to Dr. Herbert Jones, May 15th, 1922, by members of the Hereford City Parliament in recognition of his splendid services as Speaker since the inception of the Parliament in 1903." It gives us great pleasure to record this evidence of the esteem in which Dr. Herbert Jones is held in his own city. His public spirit and great administrative abilities are well known to members of the British Medical Association. He was president of the Worcestershire and Herefordshire Branch in 1915, and has been a member of the Central Council, as well as chairman of the Public Health Committee. It was largely through his exertions that the British Medical Association was able to obtain security of tenure for county medical officers of health in 1909, and last year for other medical officers of health. Speaking of his services a year ago, we observed that his keenness, assiduity, and diplomacy had at last received their reward in legislation of great public importance, since it placed medical officers of health in a position which enables them to do their duty without fear or favour. Dr. Jones has long been medical officer of health for the Herefordshire Combined Districts, having held that appointment, we believe, since the combination was formed; he possesses an encyclopaedic knowledge of the theory and practice of public health in this country. During the war he served continuously as Lieutenant-Colonel R.A.M.C.(T.).

BRITISH HOSPITALS ASSOCIATION.

The twelfth annual conference of the British Hospitals Association took place in Liverpool on May 25th and 26th, under the presidency of the Hon. Sir Arthur Stanley, G.B.E. A civic welcome was given to the members of the Association by the Lord Mayor, Alderman Charles H. Rutherford, who at once struck the note of finance, and the conference devoted itself to consideration of the financial straits in which hospitals throughout the country are placed. Sir Alan G. Anderson read a paper on "The change in hospital finance," and advised administrators of hospitals to follow the lead given by the Hospital Savings Association, a new London organization which had set up a scheme of regular monetary contributions to the hospitals among the working classes in the London area. The President voiced the opinion of the conference in stating that the public had determined that their voluntary hospitals were not to go, and those who were interested in hospitals had to bestir themselves and bring forcibly before the community the needs of these institutions. He thought that if the hospitals could tide over the next three or four years the voluntary system would reassert itself and the money would be forthcoming. Mr. H. Wade Deacon, chairman of the Liverpool Royal Infirmary, said that, generally speaking, patients were only too glad to contribute to hospital funds once they understood the need. In the subsequent discussion various methods were suggested by delegates, and there was a general consensus of opinion that contributions should not lose in any respect the inestimable value of being charitable and free-will offerings, bestowed on a cause that was directly and indirectly beneficial to all classes of society. Mr. W. Thelwall Thomas, senior surgeon to the Liverpool Royal Infirmary, read a paper on "The voluntary hospital: a retrospect and a prospect," and said that within his own personal experience the type of hospital patient had greatly altered. The necessitous poor were still as of old treated, but their numbers had diminished materially, their place being taken by a class who not only could, but would willingly, afford to contribute towards their maintenance and treatment. He pointed out that inasmuch as we had departed from the original object of the voluntary hospital, we must be prepared to modify the conditions of admission and of the medical service. He laid stress upon the point that it was not equitable that the medical profession should have so large a burden of gratuitous work thrown upon it.

Mr. Frank G. Hazell, superintendent of the Manchester Royal Infirmary, read a paper on "Hospital economies." He urged strongly the establishment of a central fund for the provincial hospitals on the lines of King Edward's Hospital Fund in London. He maintained that the voluntary hospitals should avail themselves of the important advantage

attached to judicious advertisement. Their good work should be constantly and persistently kept before the public eye, and the public should be impressed with the fact that it was for their benefit that these institutions existed. The hospitals should be first in the mind of the public when charitable bequests were being considered. A discussion ensued, and the conference eventually passed a resolution requesting the Council of the British Hospitals Association to consider the formation of a Central Fund for Hospitals outside London. The afternoon of the last day of the conference was devoted to visits to hospitals in the neighbourhood of Liverpool, and the School of Tropical Medicine also attracted many of the delegates.

Scotland.

CARE OF MENTAL DEFECTIVES.

THE Right Hon. Robert Munro, Secretary for Scotland, has recently stated in Parliament that he is considering in consultation with the Treasury whether within the limits of the financial vote for the current year certain further provision can be made for the care and treatment of mentally deficient persons in Scotland.

GLASGOW CHILD WELFARE HOME.

The Mount Blow Country Home, the third home acquired under the Glasgow Corporation child welfare scheme, was officially opened on May 18th. It stands on a hill in a wooded estate, and has at present accommodation for forty children, but on the completion of several extensions it is expected that it will accommodate two hundred. Of the children already under treatment about 70 per cent. were admitted on account of rickets. The two other homes opened by the corporation are the Mount Vernon and Scotstoun; the children are sent to these homes after being examined by the medical officers at the different child welfare centres.

FIFE PRACTITIONER AND HIS ASSISTANT.

In the Court of Session, Edinburgh, on May 24th, Lord Morison gave judgment in an action by a Fife medical practitioner against his former assistant. A report of the case appeared in the *Scotsman* of May 25th. Lord Morison said that the real question at issue was whether the plaintiff justifiably terminated the defendant's contract of service in December, 1921. In November, 1919, the parties entered into a contract (containing a restrictive covenant to prevent the assistant from practising on his own account in a given area for a term of years), which was superseded in June, 1920, by an arrangement referred to as the draft agreement. This new arrangement differed in some material respects from the prior agreement. It substantially increased the assistant's salary and, according to it, the assistant, subject to certain contingencies, had the option of entering into a five years' partnership in June, 1922. Lord Morison said that the plaintiff's desire was to find some excuse to void entering into the co-partnership. No suggestion was made against the defendant's honesty and there was no complaint of his neglect of the plaintiff's patients. In his lordship's view the defendant's application to be placed on the list of panel doctors for Fife was merely a declaration that he intended to practise on his own account if the plaintiff persisted in the attitude that he was not bound by the draft agreement. His lordship found for the defendant, with costs.

Ireland.

REGIUS PROFESSOR OF SURGERY, DUBLIN.

At a meeting of the Board of Trinity College, Dublin, held on May 19th, Sir William Taylor, K.B.E., C.B., Surgeon and Lecturer on Surgery at the Meath Hospital, was appointed Regius Professor of Surgery in succession to the late Dr. Edward Henry Taylor. Colonel Sir William Taylor, who was born in County Donegal in 1871, was educated at Strabane Academy, Dublin University, and the Royal College of Surgeons in Ireland. He has had a most distinguished professional career, and has held many important offices. He is a past President of the Royal College of Surgeons in Ireland and an honorary Fellow of the American College of Surgeons.

DANGER OF BAD MILK.

At a recent meeting of the Statistical and Social Inquiry Society of Ireland, Dr. J. W. Bigger read a paper on "Clean milk," in the course of which he stated that the chief danger involved in using cow's milk as a food for infants and children, and even adults, was not in its chemical composition, but in the presence in it of bacteria which might cause disease. It was with these bacteria, their source, and the methods used to prevent their presence in milk that his paper dealt. Bacteria, or microbes, or germs were exceedingly minute vegetable organisms of very simple type. Since the great pioneer work of Pasteur they knew that there were enormous numbers of different types of bacteria. The bacteria found in milk might be definitely harmful and disease-producing, or harmless, or those which were relatively harmless to the adult, but dangerous for young children. The chief sources of dangerous bacteria in milk were: (1) Diseases of the cow; (2) diseases of the milker, or others handling the milk; (3) the addition of dirt, chiefly excreta of the cow, either directly or indirectly to the milk. Diphtheria, scarlet fever, and foot and mouth disease might be conveyed from cows by milk, but only rarely. By far the most important disease common to both is tuberculosis. There were two chief types of tubercle bacilli, the human and bovine. The former is alone responsible for tuberculosis of the lungs or consumption, but both might affect other parts of the body, and a considerable amount of tuberculosis of the abdomen, of the lymphatic glands, and bones was due to the bovine type of bacillus. The child had much less resistance than the adult against the bovine type of disease. About 6 per cent. of all deaths from tuberculosis were due to drinking tuberculous milk, and very many children who escape death were rendered ill and weakened, or made life-long cripples, as a result of consuming infested milk. It had been estimated that 25 per cent. of milking cows suffer from tuberculosis, and 2 per cent. had tuberculous disease of the udder. He examined a series of Dublin milks and found out of fifty that four contained living and virulent tubercle bacilli—that is, 8 per cent. Public health authorities, by periodic medical inspection of workers, could usually exclude those suffering from any infectious disease, or if an epidemic should arise could trace it to its source, where it could be dealt with. Similarly, veterinary inspection of the cows should be able to exclude those whose health rendered their milk unsafe for human use.

Having dealt in detail with the precautions taken in American cities, the lecturer said that in Ireland they had no scheme for the supply of certified milk, and no maximum standard, and both were very badly wanted. If Dublin milk were on sale in Boston, 48 per cent. would have been condemned and their suppliers prosecuted. In Ireland, so long as fat was not abstracted, no offence was committed, although, in his opinion, it was a far more criminal act to sell a solution of manure in milk than a mixture of milk and water. Milk was to-day in this country sold merely as milk, and they knew nothing of its cleanliness or whether it was safe to drink. He would suggest the following requirements for a supply of certified milk for Ireland: All cows the milk of which was to be certified should be examined periodically by a veterinary surgeon, and be negative to the tuberculin test, and be otherwise healthy; all workers should be examined at intervals and pronounced free from transmissible disease; the dairy should be suitable for the purpose and be kept clean, the equipment should be of approved design, and facilities for proper cleaning be available; the milk should be cooled immediately after milking, and be sold within twenty-four hours; no certified milk should contain more than 200,000 bacteria per cubic centimetre, and lactose-fermenting bacilli should not be present in one twenty-fifth of a cubic centimetre. The fulfilment of these requirements would guarantee that certified milk was a safe food for infants and young children. His principal reason for bringing the subject before the Statistical Society was that last year in the city of Dublin 382 babies died from enteritis, and dirty milk was the cause of death in the majority of these cases. The bare figures give little idea of the sorrow and suffering caused, and, apart from all feelings of humanity, mere financial expediency would urge that the loss occasioned by this amount of disease should cease.

Discussion of Dr. Bigger's Paper.

Sir William Thompson, in moving a vote of thanks to Dr. Bigger, said that Dublin had the reputation of having the highest infantile mortality of any of the cities in Great Britain. With a sufficient amount of spirit they should be

able to get a pure milk supply. If they got that, there would, he held, be a considerable decrease in infantile mortality.

Sir William Wheeler, Vice-President of the Royal College of Surgeons, dealt with the precautions taken in America to procure pure milk. There, he said, the public authorities published broadcast the results of their examinations of the character of the milk offered for sale, and this had a very salutary effect. Attention was largely devoted to obtaining for the people pure water, and he regarded it as equally important that pure milk should be available, especially for the feeding of children. It was terrible, when going through the wards of Dublin hospitals, to see the number of children who were being bowled over by bad milk.

Professor Heuston said that there was a great laxity shown in the handling, sale, and use of milk and butter. In Dublin a great deal of the milk was of a harmful character. There he declared milk was sold at equal value whether good or abominably dirty. The authorities condemned putrid meat and fish, but there was milk and butter sold in Dublin which if examined as carefully would be found to be equally bad. A great deal of the butter used by confectioners in Dublin was unfit to be used for food, and the users ought to be hunted up and fined. If that did not help, more vigorous steps might be taken. He insisted upon the cleanliness of the surroundings of the dairies, of the persons engaged in handling milk, and of the vessels, which should be put to the severest test. Sterilization should be adopted. The public should show a desire to have and a determination to get pure milk.

The Chairman (the Lord Chief Justice of Ireland), in conveying the vote of thanks, said that there was no reason why in Dublin they should not get as good milk as the people in Boston, whose standard showed that 48 per cent. of the milk of Dublin was bad.

Correspondence.

STATISTICS OF PUBLIC HEALTH.

SIR,—The substance of Sir Arthur Newsholme's American address having been reprinted in the *Lancet* (1921, ii, 833-6), the English reader can decide for himself whether Sir Arthur's charge of misrepresentation is well founded. The first sentence of the reprinted address is:

"Vital statistics or biometrics occupy in public health teaching and administration an essentially subsidiary position, being one of several tools which the public health worker employs in his pursuit of knowledge and measurement of results. To place them on an equal footing with the fundamental sciences of biology, chemistry and physics, and of pathology, preventive medicine, and epidemiology in public health administration, or in an organized programme for the training of public health officers, appears to me to imply confusion of thought and of plans."

What, then, are the essentially subsidiary uses to which statistics may be put? In Sir Arthur's words (p. 835):

"In statistical work there has been, hitherto, too much shovelling into heaps, and too little building of the edifice of public health. No elaborate mathematical work is needed for the study which I am advocating, or for ordinary public health needs; but it is necessary that there be an observance of the well-known rules of sound reasoning, based on scientific and medical knowledge, and made with a view to make statistics act as a pointer to the areas in which excessive mortality or sickness exists, in order that, an intensive study of its vital statistics having been secured, a corresponding social and sanitary investigation may follow and the appropriate remedy may be applied."

The meaning of the first sentence in this quotation escaped me, but from the remainder I inferred that, in Sir Arthur's opinion, (a) rules of statistical accuracy and sound reasoning can be normally acquired without special training; (b) that the sort of training given in a department of biometry and mathematical statistics is waste of time for the student of preventive medicine; (c) that the primary function of the enthusiastic statistician is to call attention to something which has been done by adepts in the "fundamental sciences" or ought to be done by them.

Your readers will now judge whether I "failed to express accurately" Sir Arthur Newsholme's stated views.—I am, etc.,

Loughton, May 27th.

MAJOR GREENWOOD.

STAIN FOR BLOOD FILMS.

SIR,—Dr. J. Shulman asks a question in the *Journal* of May 20th (p. 826) which demands a somewhat detailed answer. The method of staining blood films with haemalum and eosin is probably known to all workers in haematology, but it is a method of only limited applicability.

The determination of the relative numbers of the different types of leucocytes in the blood depends upon a very detailed analysis of their structure. It is necessary to use a stain which will distinguish the details of nuclei and granules, and these latter may be neutrophile, eosinophile, basophile, or azurophile. Staining with haemalum and eosin cannot be expected to supply all this information; it is a valuable method of staining when the investigation of nuclear detail is the only object, and even the eosinophile material becomes a noticeable feature, but finer points such as azurophilin in large hyaline mononuclear cells and large lymphocytes cannot be detected. In order to obtain the best demonstration of nuclear detail with haemalum it is necessary to use films which have been fixed while still wet, and in these circumstances it is found that the red corpuscles are much deformed; it seems unlikely that the leucocytes are not also somewhat altered in shape. In films which have been allowed to dry before fixing the cells have an opportunity of returning to their ordinary shape. Jenner's stain is excellent in many ways, but it does not demonstrate the details of the nuclei very distinctly, and this makes it difficult to appreciate the structure of the myeloblast. If it is employed in the May-Grünwald manner, instead of the usual way, brighter results are obtained. Leishman's stain is extremely useful, but it does not give distinct pictures of the neutrophile elements of the leucocytes, although its rendering of nuclear detail is superior to that of Jenner. Giemsa's stain requires more experience if good results are to be obtained, but is a very excellent method, except that it, like Leishman's, does not render the neutrophile granules distinct. The best method available for routine haematological work is undoubtedly Pappenheim's panoptic, or the same author's panchrom, method. These methods depend upon the use of Jenner's method and counterstaining with Giemsa, or, preferably, panchrom, which is very similar to Giemsa stain, but contains an even greater variety of intermediate products of methylene blue.

The technique of staining is as follows:

1. Fix the dried films for three minutes with undiluted Jenner.
2. Dilute the Jenner with an equal part of distilled water and stain for one minute.
3. Pour off the diluted stain, but do not wash, and then pour on diluted Giemsa or panchrom. The dilution consists of 2.5 c.cm. of the stock stain in 10 c.cm. of distilled water; this should be made up in the vessel in which the azur tends to adhere to glass and in some other vessel and then poured.
4. Dry by blowing off the superfluous water and swigging about. Do not use heat, as this destroys the azur staining.
5. Mount in neutral balsam or euparal while there is still a trace of water present in the film.

This method should succeed every time it is tried; the only points requiring great care are the removal of all traces of acid from the glassware used and the freshness of the dilution of the Giemsa, which keeps only about half an hour. Further details about this method can be found in Pappenheim's *Technik und Methodologie der klinischen Blutuntersuchung*, 1919, second edition, p. 56. I have found no stains so satisfactory as those of Grübler.—I am, etc.,

ALFRED PINEX, M.R.C.P. Lond.

Pathological Department,
The University, Birmingham.
May 20th.

EXPECTANT TREATMENT OF MEASLES AND INFLUENZA.

SIR,—Dr. Carruthers, in his letter to the *British Medical Journal* (May 13th, p. 786), asks, "When will we learn to break away from the tradition of the textbooks and the fever hospitals?" I write to say that I did so many years ago, and have never regretted the step. During the past sixteen years I have treated over 200 cases of measles without a single death by the use of the following measures, which are somewhat similar to those suggested in Dr. Carruthers's letter: Avoid the use of all drugs other than aperients. Only allow drinks of water, diluted fruit juice, and when sweetened with a little honey, till the temperature drops and the patient himself begs for something to eat. And keep him in bed until the cough is gone.

A brief account of my experiences in the tropics during an influenza epidemic of a virulent type may also be of interest. Twenty of my bad cases with high temperature, headache, general ache, and profound prostration volunteered to try the "water cure." They lived on nothing but water, strained orange juice, and a little weak tea, for four to six days, when the temperature came down and appetite manifested itself; then food was allowed. The first day's diet consisted of vegetable soup, milk, and fruit. On the second day toast-and-butter was given in addition. Later a little fish or chicken

with plenty of conservatively cooked vegetables was added. No drugs were administered other than a saline purge, which was taken daily throughout the period of abstinence from food. Within eight to ten days from the time of going sick every case was fit and well enough to return to duty, and all had excellent appetites for even the plainest of meals.

I was not so successful, however, in other cases that insisted on getting textbook diet—milk, beef tea, egg flips, etc.—from the very commencement of their treatment. Few of them escaped the textbook complications—gastritis, bronchitis, pleurisy, or pneumonia—while one got double pneumonia and died. Most of them were unfit for work for two or three weeks, and some even longer.

There is no doubt in my mind that indigestion toxæmia is caused by coaxing or forcing nourishment into a stomach that is unable to deal with it properly, owing to absence of appetite, and is the chief factor in the production of the complications so often met with in measles, influenza, and other diseases. The wasted bodies of those who have been fed during acute illnesses is clear evidence to me that the nourishment given has not been digested, let alone assimilated. To waste away and die from lack of food is not a matter of days, as so many of us have been taught to believe, but probably of weeks. It is certainly a period far beyond the average time of recovery from acute diseases.—I am, etc.,

REGINALD F. E. AUSTIN,

Major, late R.A.M.C.

London, W., May 13th.

THE SEARCH FOR SPECIFIC REMEDIES.

SIR,—With reference to the action of emetine on fresh and vigorous amoebæ, referred to in the leading article in the *BRITISH MEDICAL JOURNAL* of May 20th, may I point out that your deduction that the surprising results of methyl-emetine, dimethoxy-emetine, etc., were proportional not to their direct action on the amoebæ but to their poisonous action on the patient, is not fair, for it is quite probable that the fact that dimethoxy-emetine, which had ten times the poisonous action on amoebæ compared with the others and yet was clinically inert, is to be accounted for on the view, supported in the first place by the Italian observers Zancanol, Celli, and Fiocca, that streptococci are the active agent, rather than amoebæ, in causing the clinical symptoms of so-called amoebic dysentery. I worked on this theory in a case of Hodgkin's disease, verified by opinions of high standing, in which there were rigors and a septicæmic condition, with the passage of bloody stools, quite "amoebic dysenteric" in nature; although the case was despaired of, I rapidly brought the patient round by injections of emetine hydrochloride gr. 1, night and morning, for a few days, on the hypothesis that Hodgkin's disease is caused by a streptococcal blood infection and should be amenable to the same treatment—namely, emetine—assuming the Italian observers were right. The glands in this case yielded to radium treatment, and, except for anaemia, the patient is well and has been able to attend to his duties and work since. Further, the article states that the nature of the co-operation between the remedial agent and the living tissues is hard to unravel; no doubt Ehrlich's side-chain theory is biochemically very right as it stands, but the ultimate fact is the action of remedial agents causing glandular hormonal balance.—I am, etc.,

London, S.E., May 22nd.

REGINALD LARKIN, M.D. Lond.

DETOXICATED VACCINE.

SIR,—Dr. Jenkins, in a letter in your issue of May 27th (p. 858), says: "The fact that they [that is, bacterial split products] may act as efficient antigens proves nothing." This statement is too sweeping, and receives no justification from his allusion to the Wassermann reaction, since no one pretends that the extract in this test is an antigen or the body tested for an antibody.

The presence of a true antibody when tested for by a true antigen, as in the gonococcus complement-fixation test, may be taken as evidence of an attempt at immunization of some sort. But whether this is immunization against the whole bacterial protoplasm or only part of it is another matter. I believe that in the case of chemically treated vaccines an alteration of antigen takes place, yielding only a partial antigen, or at least leaving only a portion of the original antigen unchanged, the result being only partial immunization. This, I think, accounts for the disappointing results of detoxicated vaccines, even though some kind of antibody may be found in considerable amount. H. G. Wells and others have shown the possibility of splitting up proteins into several specific antigenic fractions.

A BUILDING is to be erected in Winnipeg to be used exclusively by medical practitioners and dentists; it is stated that the rents will be controlled by those who take part in the enterprise and that the building will be erected in a side street to avoid high charges.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Boyle Lecture.

THE Boyle Lecture of the Oxford University Junior Scientific Club will be held on Tuesday evening, June 7th, at 9 o'clock, in the D.Sc. "Life" by Professor W. M. Bayliss, M.A., "The subject of the lecture is

UNIVERSITY OF CAMBRIDGE.

Diploma in Psychological Medicine.

A SHORT course of instruction for the D.P.M. examination will be held in Cambridge from July 12th to August 17th. The following lectures, etc., will be given: (a) Anatomy and Physiology of the Central Nervous System, with practical work (Dr. Roberts). (b) Psychology, with practical work (Mr. Bartlett and Dr. Miller), mental tests (Miss Fildes). (c) Psychopathology and Psychotherapy (Dr. MacCurdy, Dr. Noble). (d) Psychology and Pathology of Dreams (Dr. Rivers). (e) Mental Diseases, with clinical work (Dr. Archdale). (f) Mental Deficiency (Dr. Tredgold). The names of those who wish to take the course should be sent to the Secretary, D.P.M. Committee, Psychological Laboratory, Cambridge, by July 5th if possible.

Dr. H. B. Roderick, O.B.E., has been reappointed Demonstrator in Surgery for three years.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

THIRD M.B., B.S.—Honours: *E. C. Dodds, J. C. M. Gwilliam, Lily G. Hiff, *M. Maizels, J. G. Massie, *Merrell P. Middlemore, J. D. C. Norris, *J. A. C. Perry (University Medal), *Philipa P. Pugh, *E. H. Richards, *H. H. Weatherall, *A. D. Wright.
Pass: Janet Kaitken, Helen R. Ashton, E. T. Bailey, K. N. G. Bailey, E. Biddle, Hilda C. Bowser, Edith K. Budden, Jean E. Callander, P. C. L. Carrier, Anaple F. M. Christie, Alison M. Collie, Gwendolen C. Cotton, A. H. Douthwaite, Elizabeth C. Eaves, K. V. Edwards, F. T. Evans, Hilda M. Garlick, J. F. Hackwood, Doris M. Hammond, O. S. Hillman, Margaret O. Howell, F. C. Hunt, Erna H. Jebens, Winifred M. Jenkins, J. N. Kerr, H. T. Leveux, C. G. Lewis, R. C. Lightwood, D. McClean, H. J. McCurich, E. K. Macdonald, S. A. S. Malkin, Eva J. Newton, Winifred C. UNIVERSITY COLLEGE.

Applications for the Sharpey Physiological Scholarship, value £200 a year, must be received by the Secretary of the College, Gower Street, London, W.C., by June 15th.

The Services.

ROYAL NAVY AND ARMY MEDICAL SERVICES.

Parkes Memorial Prize.

THE Parkes Memorial Prize of 75 guineas in money with a gold medal is due to be awarded in 1923. The subject for the next competition is, "The principles of the prophylaxis of malaria, with the administrative and other measures for their application on active service." Essays must reach the Secretary of the Prizes Committee, Royal Army Medical College, Millbank, S.W.1, on or before August 1st, 1923. Each essay must bear a brief motto, and must be accompanied by a sealed envelope similarly superscribed and containing the name and address of the author. The Prizes Committee reserves the right to withhold the award should, in the opinion of the assessors, no essay attain a sufficiently high standard of merit. The successful essay becomes the property of the Prizes Committee.

The competition is open to the medical officers of the Royal Navy, Army, and Indian Army, of executive rank on full pay, with the exception of the professors and assistant professors of the Royal Naval Medical School, Greenwich, and of the Royal Army Medical College, London, during their term of office.

Royal Army Medical Corps: Alexander Memorial Prize.

The Alexander Memorial Prize of £50 with a gold medal is also due to be awarded in 1923. The subject for the next prize is, "Secondary wound shock; its causation, prevention, and treatment." Essays to be sent to the secretary, "Alexander Memorial Prize," Royal Army Medical College, Millbank, S.W.1, on or before August 1st, 1923. Each essay to have a motto and to be accompanied with a sealed envelope bearing the same motto and containing the name of the competitor. The competition is open to Medical Corps on full pay, with the exception of the professors and assistant professors of the Royal Army Medical College during their term of office.

I.M.S. DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 14th, at 7.45 p.m., with Lieut.-Colonel J. Anderson, C.I.E., in the chair. All particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 63, Addison Road, Kensington, W.14.

Medical News.

SIR JOHN ROSE BRADFORD has been elected vice-chairman of the University College Committee. He will represent the University of London at the unveiling of the memorial to Pasteur in Strasbourg next spring. Pasteur was born on December 17th, 1822, but the ceremony at Strasbourg will, we understand, take place in May.

THE annual general meeting of governors of Epsom College will be held at 49, Bedford Square, W.C., on Friday, June 23rd, at 4 p.m., when the result of the voting for pensioners and foundation scholars will be announced.

THE Yorkshire Association of Medical Women held a dinner in the Leeds Medical School on Saturday, May 27th. Miss Aldrich-Blake, M.D., M.S., was the guest of the evening, and spoke on some of the aims and ideals of the Federation.

It has been proposed by Dr. Freeland Fergus of Glasgow that members of the Hunterian Society (of London) who are present at the Annual Meeting of the British Medical Association in Glasgow should have the preference for an excursion to Long Calderwood, the birthplace of John Hunter. Various places of interest will be pointed out by Dr. Fergus, who will proceed with the excursion—such as the birthplace of David Livingstone, and the village of Bothwell, associated with the names of Joanna Bayley and Matthew Bayley. The exact cost of the excursion is not known, but it is thought that it will be considerably under £1. Will those members of the Hunterian Society who wish to take advantage of this invitation kindly communicate with Dr. Freeland Fergus, of 14, Newton Place, Charing Cross, Glasgow?

THE late Colonel Harry Littlewood, C.M.G., F.R.C.S., formerly of Leeds, has by his will bequeathed £1,000 to the University of Leeds upon trust for investment, and to apply the income in providing annual or biennial prizes in the anatomy department, to be awarded by and at the discretion of the professor of anatomy for the time being. The value of the testator's estate was sworn at £85,785, with net personality of £70,905.

THE Congress of Radiology and Physiotherapy commences at the house of the Royal Society of Medicine (1, Wimpole Street, W.1) on Wednesday next, June 7th, and continues to June 10th. There will be three sections—radiology, physiotherapy, and electrology. At the morning meeting of the first section a discussion on the conditions of the normal stomach will be opened by Dr. Barelay (Manchester), Dr. Peremans (Antwerp), and Drs. Colombier and Tribout (Paris). At the afternoon meeting of the section Dr. Bèclère (Paris), Dr. Murdoch (Brussels), and Sir Archibald Reid will open a discussion on the abnormal stomach. On Thursday and Friday deep therapy by x-rays and radium will be discussed by this section. In the afternoon of June 9th demonstrations will be given at various hospitals, including one at St. Bartholomew's Hospital on intraperitoneal injection of oxygen. In the section of electrology Dr. Turrell (Oxford) will open on June 7th a discussion on the action of direct current (constant) on the tissues beneath the skin and mucous membrane. On the following day Dr. R. Woods (London) and Dr. Bonrguignon (Paris) will introduce a debate on the uses of electrical methods in the diagnosis and prognosis of paralysis, and on Friday, June 9th, Dr. Cumberbatch (London) and Dr. Nobelet (Ghent) will discuss the physiological and therapeutic uses of high-frequency currents. The section of physiotherapy has selected cardiac disorders as the first subject for discussion, to be introduced by Professor Bergonié (Bordeaux) and Drs. Justina Wilson, Parsons Smith, and Hunt (London). On June 8th the re-education of muscles and the treatment of scoliosis will be discussed, and on Friday, June 9th, the discussion will refer to backache and referred pain.

A TWO-DAY conference on mental deficiency will be held at Caxton Hall, Westminster, on Wednesday and Thursday, July 26th and 27th, 1922, under the auspices of the Central Association for Mental Welfare (formerly the Central Association for the Care of the Mentally Defective). The first day will be devoted to discussion of "Mental deficiency in relation to crime," and Lord Justice Atkin will give a concluding address. The second day will be devoted to educational matters, and the Right Hon. H. A. L. Fisher will attend and address the conference. Further details may be obtained from the honorary secretary, Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1.

THE Ministry of Pensions announces that arrangements have been made, in co-operation with the Ministry of Health, for the provision at certain institutions for the treatment of tuberculosis, of facilities for vocational training, combined with treatment, which if satisfactorily completed should enable disabled men to become efficient workmen and to earn a livelihood at the occupation in which they have been trained. Applications for admission to the training courses will be considered if the applicant is resident in England; if he is suffering from tuberculosis accepted as attributable to or still aggravated by service in the great war; and if he is certified to be in consequence of that disability unable to follow his pre-war occupation or (without a course of training) any other suitable occupation, and it is necessary that he should be trained for another occupation. With certain exceptions applications must be made on a prescribed form through any Local War Pensions Committee not later than June 30th, 1922. No man will be admitted to training whose course cannot be completed by June 30th, 1924. These arrangements do not apply to officers or nurses.

THE Voluntary Hospitals Commission announces that it has decided to convene a conference of representatives of local hospital committees on Tuesday and Wednesday, July 18th and 19th, at the Ministry of Health. It is hoped that all local hospital committees will be represented by their chairman and secretary, but other members of committees will be welcome if they care to attend, and no limit will be placed upon the number of representatives from any particular committee. Cards of admission will only be sent to those persons whose names have been notified to the Commission not later than July 10th.

A GIFT of £10,000 has been made to aid cancer research by Mr. and Mrs. G. F. Todman, of Sydney, N.S.W., in memory of their daughter. At the request of the donors Sir Joseph Hood, M.P., has allocated the sum as follows: £4,000 to the Imperial Cancer Research Fund, Queen Square, Bloomsbury; £1,000 each to the Middlesex Hospital, the Cancer Hospital, Fulham Road, London, the Christie Hospital, Manchester, the MacRobert Endowment, Aberdeen University, and the Cancer Hospital, Glasgow; and £500 each to the Radium Institutes of London and of Manchester.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attitology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

SYMPTOMS PRODUCED BY PARATHYROID.

"W." who finds in the paper on calcium deficiencies treated by parathyroid published by Drs. Grove and Vines in our issue of May 20th (p. 791) the statement that "in no case has there been any symptom of overdosage," asks for information as to the nature of such symptoms.

** We referred the question to Dr. Grove, who writes: The literature is very indefinite on the subject of overdosage by parathyroid; what has been recorded is mental rather than physical, following enormous doses long continued, and was probably *post* rather than *propter*. In none of our cases (several hundreds) with the doses we have recommended were any untoward symptoms noticed or complained of, but one of our correspondents says that a female patient gave up treatment because she thought it gave her headache. We have obtained the definite result of normal blood with the small dose (a tablet a day), and where the blood has been long reaching normal we have not found that twice a day has hastened matters.

MEDICAL SECRECY.

A CORRESPONDENT asks us to add to the article on the Hippocratic Oath, published on May 20th, an account of "the practice in the courts about Hippocrates' time and subsequently in the matter of medical witnesses."

** We fear that his wish cannot be complied with, for no reports of medical evidence in ancient Greece appear to have survived. In the Roman Empire the medical witness must have had (pace the edict of Julius Caesar) whatever privileges belonged to a Roman citizen. There are scattered references in the middle ages—for example, Erasmus (1500) states "the sublime imperial and pontifical laws voluntarily submit to the judgement of the physicians in questions of puberty, birth, and poisoning, and also in some matrimonial questions."

OSMICS AND PSYCHO-ANALYSIS.

MR. JOHN H. KENNETH, M.A., F.R.S.G.S. (Animal Breeding Research Department, High School Yards, The University, Edinburgh), who thinks that osmics—the science of smell—may be of use in psychotherapeutic practice, asks medical practitioners for their experience of the practical use of olfactory stimuli in psychotherapy. He writes: In the course of experiments on olfactory fatigue and on associations and affects evoked by different smells, the remarkable visual and (to a lesser degree) auditory recollections of scenes and events, in some cases of more than twenty years ago, hitherto forming part of unconscious memory, were extremely vivid, as expected. The same olfactory stimulus may, of course, release varied associations or groups of associations in minute detail. An emotional disturbance may be produced, and in the presence of a complex a marked resistance is noticeable, the smell stimulus being quite as potent as a word stimulus. Of the odorous substances experimented with, musk, otto of roses, tonka bean (cumarin), and cedar-wood oil gave the most vivid results, while resistances were encountered in certain cases with musk, clove oil, and asafoetida. Experiments with the galvanometer will be carried out in due course.

INCOME TAX.

"J. F." inquires whether he is entitled to deduct, for the purposes of an assessment under Schedule D, expenses incurred in travelling in and about London to attend at two centres where he did Ministry of Pensions work on a fee basis.

** If he is assessed under Case I, Schedule D, as for profits of carrying on a profession, we think that the expenses could be deducted; if he is assessed under Case III, Schedule D, we consider that the only expense that can legally be deducted is the expense of travelling between the two centres.

"T. McC." for many years did not claim all the expenses to which he was entitled—for example, he did not claim a deduction for the board and wages of an indoor servant. He asks what remedy he is now entitled to claim.

** Unfortunately none; in the circumstances of his practice he could properly have claimed one-half of his total rent and rates and the cost of one maidservant, but his right of objection to an assessment is limited to the period of twenty-one days from the date of the formal notice of assessment, which was presumably sent to him. In all the circumstances the local inspector might reasonably concede an adjustment of the assessment for 1921-22—by reducing the July instalment of tax—but "T. McC." has no legal title even to that.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at pp. 219, 220.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page...	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

521. Re-educational Treatment of Confirmed Stammerers.

CLARK (*Med. Record*, April 15th, 1922) considers that the essential fault in confirmed stammering lies deep in the character formation, of which the stammering is merely a symptom, and that success in treatment depends upon a painstaking analysis and synthesis of the personality, as well as upon proper speech gymnastics—in short, the individual must be treated and not the stammering. In order to deal with the condition upon psycho-biologic lines a psychiatric training is essential, and, following upon a thorough analysis of the morbid trend in the developing character, synthetic re-education is needed. The condition must be regarded as a syndrome of the effective life of self-expression, and nothing short of a neuro-psychiatric training treatment will permanently relieve it. Notes of three cases are given at length, specially indicating that part of the history in each which bears upon the contention that the inherent defect is due to an arrest of the whole instinct of self-expression. By finding first the basic interest, and then moulding it into a trial social group, is the direction in which lasting improvement must be sought. In the three cases recorded this was attained in one patient by the social usefulness of a medical career, in another through athletic and engineering interests, and in the third in a business training and possible financial career. The speech disorder of the confirmed stammerer is quite different from the faulful speech defect of the neurotic and hysteric, the neurotic element in the confirmed stammerer being confined solely to his substitutive reactions in seeking expression, and not to the fundamental defect of speech itself. The analysis should synchronize with the synthesis rather than precede it, the analysis being used after a time only to get at the deeper roots of some morbid trend of manner or speech. The basic character fault which precedes the stammering is in the main summated in a shyness and timidity toward all forms of self-expression, and the feeling of inferiority becomes accentuated by the active or passive resistance exercised toward "the great nucleus of authority in the home" which has repeatedly repressed the self-expression of the constitutional stammerer. The habit training should begin simultaneously with the first efforts to overcome articulatory defects, the manner and substance of the first lesson in training being suited to the individual, illustrated by examples of free and easy speech in newspaper accounts, and finally by creating situations requiring spontaneous natural effort at self-expression. Thus, says the author, by analysis and re-education of the personality defect as a whole, together with intensive special speech gymnastics, can a cure be effected.

525. Industrial Dermatitis.

McLACHLAN (*Glasgow Med. Journ.*, April, 1922) calls attention to a dermatitis of the hands and forearms occurring among workers in lubricants used in cutting metal, various oily mixtures and greasy pastes mixed with water being utilized for cooling, lubricating, producing smooth finish, washing away chips, and protecting from rust and corrosion. Working with carefully prepared sulphated compounds, or those made from any good potash or soda, soap, or natural petroleum oil, is comparatively free from risk, the danger lying in the continual wetting of the skin by watery fluid, often dirty and containing metallic chippings, the presence of an excess of free alkali or impure anthracene oil, or some ingredient in the composition. Three distinct types of lesion occur: (1) A folliculitis arising apparently from plugging of the follicles with oil or dirt; (2) an eczematoid eruption exhibiting either erythematous-sealy patches or a vesicular or pustular dermatitis; and (3) pigmentation and infiltration of the skin, keratotic patches, wart-like growths, ulcerations, and occasionally epitheliomatous changes. Symmetrical in distribution, the lesions occur on the backs of the hands, especially in the interdigital spaces, and on the forearms. Improvement rapidly follows cessation from work and treatment with simple boracic dressing. Bacterial contamination through the habits of the worker is a possible risk, and may be a source of secondary infection of a dermatitis originated by the chemical irritant in the oil. All the mixtures used were found to contain free fatty acid and copper, and the metal worked upon may be a participating causal factor, particularly if it is copper in the presence of free fatty acid; individual

idiosyncrasy may have an important bearing upon the causation and development of the condition. Personal and occupational hygiene is essential in prophylaxis, and temporary cessation from work in treatment.

525. Occipital Lobe Embolism.

WOODS (*Journ. Nerv. and Mental Dis.*, February, 1922) records two cases of occipital lobe embolism, in the first of which a traumatism of an inflammatory focus in the upper cervical vertebrae caused immediate paraesthesia and weakness in the left arm and leg, and sudden loss of vision in the fields subserved by the calcareous region of the left occipital cortex, with recovery in the lower quadrant. The second case was a man with slight valvular heart disease, sudden dizziness with hemianopsia, visual paraesthesia, and tingling in the extremities; some disorientation occurred while riding, and was followed later by partial recovery of the visual fields. Prognosis in such cases depends upon the immediate cerebral lesion, and the nature and gravity of associated lesions elsewhere. Emboli in the posterior cerebral region may travel through the carotids or vertebrals, since the direction of the current through the posterior communicating arteries in the circle of Willis may vary according to the demands for blood from the anterior or posterior portions of the hemispheres. Though the insufficiency of collateral connections of the terminal cortical arterioles makes infarction almost inevitable, partial recovery of function is explained by the existence of a slight collateral circulation, and by the fact that in traumatic cases there is gradual recovery from any concurrent concussion of neighbouring cells.

526. Iron in Post-Influenza Anaemia.

LINDBERG (*Acta Medica Scandinavica*, vol. lvi, fasc. ii, 1922) has observed 19 cases of profound anaemia which he traces to a recent attack of influenza. In as many as 18 cases the patients were women, and most of them were middle-aged. The anaemia did not in any case develop in direct continuity with the attack of influenza, but some months later. In 17 cases the influenza itself had been of an apparently mild and benign character, and only in two cases had there been serious complications. The most prominent symptom was lassitude, and in a few cases there was shortness of breath. In no case was the haemoglobin above 50 per cent., and in 12 cases it ranged from 15 to 30 per cent. In 10 cases the number of red cells was below 24 million. The leucocytes showed no pathological changes, but the red cells showed various abnormalities. There was, however, no evidence of pernicious anaemia, such as a high colour index. Encouraged by the researches of Lichtenstein into the effects of large doses of iron on the anaemia of infancy, the author treated his cases with heroic doses of reduced iron, 1 gram being given three times a day before meals as a powder with 0.5 gram of sugar. The results were prompt and obvious; in about 70 per cent. of his cases the haemoglobin was doubled within two months, and in three cases it was trebled within six weeks. With this improvement in the blood picture there was a notable change for the better in the clinical picture, and in no case were symptoms of poisoning by the iron observed. It did not even induce constipation. The cheapness and simplicity of this line of treatment are also stressed by the author, who found that arsenic and the timid exhibition of small doses of organic preparations of iron were useless in this class of anaemia.

527. Syphilis of the Bronchi and Lungs.

BALZER (*Paris med.*, January 21st, 1922) states that modern methods of investigation have shown that syphilitic affection of the respiratory system is more frequent than was formerly supposed. Tertiary tracheo-bronchitis leading to ulceration and stenosis has long been known; but it is only within the last few years that chronic bronchitis with emphysema of the bases and more or less bronchial dilatation has been described in the secondary and tertiary stages. The symptoms are dyspnoea and paroxysmal cough. The dyspnoea is often of long standing, and may even date from childhood. It is increased by effort and gives rise to attacks at night resembling asthma. There is little or no fever. There may be impairment of resonance at the apices, with harsh inspiration, prolonged expiration, and diffuse bronchitic râles. The sputum does not contain tubercle bacilli. In syphilis, as in tuberculosis, the specific inflammation is centred in the bronchi. This explains why bronchial dilatation is observed in a variable degree in most cases of pulmonary syphilis.

In congenital syphilis the lung may be affected as early as the third, fifth, or sixth month. At a later stage it is observed between 3 and 15 years, and even between 15 and 20 (Castex and Queirel). Cases of pulmonary hereditary syphilis have been seen as late as 34 or even 40 years (Lancereaux). In the child, as in the adult, pulmonary hereditary syphilis sometimes presents a latent prodromal stage, which is sometimes very long, in which the only noticeable feature is impairment of the general condition and a tendency to bronchitis. Cough with muco-purulent expectoration, chiefly at night, is observed. The dyspnoea, which also occurs at night, is aggravated by effort and becomes permanent. The patient may suffer from vague pain in the back, perhaps due to pleural lesions. The usual site of the lesion is at the base or hilum of the right lung, and sometimes at both bases and apices. In an advanced stage bronchiectasis almost always occurs which is more or less localized in the bronchi of a pulmonary lobe. In the adult the following forms may be found: (1) Circumscribed gummatous or sclero-gummatous pulmonary syphilis, which may be associated with pleural or glandular lesions. (2) Diffuse pulmonary syphilis or subacute or chronic bronchopneumonia. (3) Rarer varieties resembling the pneumonia of the newborn. (4) Brown induration. (5) Bronchial and mediastinal adenopathy associated with pulmonary syphilis. The principal anatomical distinction between pulmonary syphilis and tuberculosis is that in tuberculosis all the three coats of the arteries are attacked, while in syphilis the tunica media resists for a long time and may escape altogether. The process is definitely syphilitic when the adventitia presents groups of plasma cells, newly formed capillaries, and elastic fibres.

528. Treatment of Trigeminal Neuralgia with Trichlorethylene.

MAGUNNA (*Klinische Wochenschrift*, March 25th, 1922) mentions the previous observations on this treatment. Plessner in 1915 reported 4 cases of poisoning through trichlorethylene in which the chief symptom was anaesthesia in the distribution of the trigeminal nerve. On account of this symptom Oppenheim urged its trial in trigeminal neuralgia. Plessner tried it in 17 cases of neuralgia and found it of service in 12. Magunna records the results in the treatment of 20 cases of true trigeminal neuralgia: 10 to 20 drops of trichlorethylene, occasionally more, are dropped on to cotton-wool; the patient breathes it for several days in succession, sometimes twice a day or more frequently. Of the 20 cases, 5 cases were completely cured, 6 considerably improved; in 9 cases the treatment failed. Sometimes this treatment is of service for the relief of the headache and sickness which occasionally follow lumbar puncture. The author concludes that trichlorethylene is of service in many cases of true trigeminal neuralgia, or at least diminishes the pain, and as no undesirable effects are observed, this treatment is worthy of further trial.

SURGERY.

529. Carcinoma of the Jejunum.

DENIS and CHARRIER (*Journ. de Méd. de Bordeaux*, April 10th, 1922) describe the case of a woman, aged 55 years, suffering from gastric disturbances. The chief symptom was profuse greenish vomiting. In addition to this she exhibited all the signs of dehydration: dry tongue, dry skin, scanty urino, and loss of flesh. Examination of the abdomen revealed nothing abnormal; x-ray examination showed no signs beyond an inability to distinguish clearly the pyloro-duodenal region. An operation was performed later, and a neoplasm was found in the jejunum, 15 cm. from its origin, encircling the gut. Resection of the growth was carried out and an anastomosis performed. The patient made a satisfactory recovery, but the growth recurred four months later in the spine. The authors point out that in this case there was a single characteristic symptom—namely, abundant greenish-coloured vomiting containing, as in cases of pyloric stenosis, undigested portions of food. The relative infrequency of cases showing the signs of duodenal occlusion makes this case of interest. In addition to the profuse vomiting one may find in this condition symptoms of gastric disturbance, such as pain without any relation to food sensation, of fullness, and constant nausea; signs of intoxication, such as are usually found in cases of duodenal stasis, jaundice, wasting, and evidence of dehydration. The x-ray signs are variable, but if present they are very definite; in this case the bismuth meal reached the duodenum, but there it remained or passed very slowly. In most cases the cause of this condition is due to peritoneal adhesions or a congenital defect of the primitive mesentery. It is extremely rare to find it develop in the case of a growth of the small intestine. The

explanation suggested is that the bile itself produces a spasm at the site of the growth, causing complete obstruction. This case shows that an obstruction in the jejunum may give all the signs of duodenal stenosis.

530. Non-Operative Treatment of Ureteral Calculi.

BUERGER (*Med. Record*, April 1st, 1922) advises cystoscopic intervention in almost all cases of ureteral calculus, soon after the stone has become lodged in the ureter, as opposed to the method of awaiting spontaneous expulsion, when the stone is not too large to pass. By the passage of ureteral catheters of varying sizes, or by the simultaneous passage of bougies and catheters, or bougies alone, drainage of the ureter can be established, and the descent of the stone facilitated. By emptying the renal pelvis such catheterization is most effective in the relief of pain and in the prevention of renal complications, and the establishment of chronic hydro-nephrosis, which might result while awaiting spontaneous expulsion, is thereby prevented. In all cases of calculus obstruction cystoscopic treatment should be carried out unless the stone is passed within three days. Recurring attacks of pain usually indicate retention of urine, and treatment should be given during the free interval.

531. Decapsulation of the Kidneys.

FAWCETT (*Guy's Hospital Gazette*, January 21st, 1922) discusses decapsulation of the kidneys in subacute or chronic parenchymatous nephritis, and quotes the case of a man, aged 39, suffering from subacute tubal nephritis, with some interstitial change and naemia. Under treatment in hospital for three months the blood urea fell to normal—namely, 0.29 gram per litre—and his general condition improved, the haematuria disappeared, and the oedema, headache, and dyspnoea became less, though the quantity of albumin remained high at 8 to 10 parts per 1,000. During two months' absence from hospital the symptoms returned and decapsulation of both kidneys was performed. The patient rapidly recovered from the operation, and within three or four days the oedema and albumin became considerably lessened, though not entirely disappearing, and his general condition has remained satisfactory. The presence of cardiovascular and interstitial changes in addition to the tubal nephritis accounted for there not being still greater improvement, since such good results cannot be expected in the former type of case as in the latter. Decapsulation is contra-indicated in all cases of advanced granular kidney with high blood urea and deficient urea excretion.

532. After-Treatment of Small-flap Sclerotomy.

HERBERT (*British Journ. of Ophthalmol.*, February, 1922) considers that the best results obtained in small-flap sclerotomy, and in increasing the effect of an ill-cut flap follow Cruise's method of after-treatment by the application of finger pressure to the eye from the beginning, thereby preventing immediate healing. This principle of very early interference with healing probably accounts for the good results which follow allowing the patient to be up and about the day after operation, so that almost from the beginning the frequent blinking movements operate in much the same way as the more infrequent finger pressure. Such application of gently sustained pressure through the lower lid may be begun on the afternoon of the operation and be repeated two or three times daily, thus partly emptying the anterior chamber. The patient should be encouraged to keep the eyes open and to blink frequently, a pad being placed over the eye which has been operated on for the first night or two, and a shield through the day. This simple procedure makes all the difference between failure and success in some cases, and it ensures success in the majority of primary glaucomas needing operation.

533. Diaphragmatic Hernia.

DURING recent years the study of hernia through the diaphragm has received marked stimulus, for two reasons: a number of cases have been observed as the result of the great war, whilst x-rays have demonstrated the condition on numerous occasions. BORDEN (*Annals of Surgery*, April, 1922) records a case of this nature, possibly congenital or following an acquired rupture. The condition may be due to congenital defect of the dome of the diaphragm, or it may occur round the oesophageal opening, due to an absence of muscular tissue. The causes of acquired herniae are increased intra-abdominal pressure and direct injury. The former may occur in crushing accidents, difficult labour, or from straining. Direct trauma follows a penetrating wound. The stomach is most commonly found in the hernia, whilst most of the other abdominal viscera have been recorded there. A hernial sac may be present. The hernia always passes from the abdomen to the thorax because of the negative pressure in the chest during inspiration and positive pressure

in the abdomen. No definite symptom complex can be given. The symptoms depend on the size of the defect and the effect on the organs involved. X rays are of the greatest value, and careful physical examination often helps in diagnosis. Surgery is the only curative treatment, and the abdominal route is undoubtedly the best means of approach. When reduction is difficult a thoracotomy may be necessary in addition. A left rectus incision is recommended for good exposure, and the hernia usually reduces without difficulty. Repair of the diaphragm is effected by bringing together the pillars of the opening with catgut sutures; if too large for suture perhaps the stomach or mesentery may be used to close the rupture effectually.

534. The Danger of General Anaesthesia in Cyclic Vomiting.

ISELIN (*Schweiz. med. Woch.*, April 6th, 1922) diagnosed acute appendicitis in a girl between 4 and 5 years old, whose symptoms included frequent vomiting. A general anaesthetic (chloroform) was given and appendicectomy performed: the appendix proved to be macroscopically healthy. Death occurred on the evening of the following day, during which the child was much cyanosed. With this disastrous mistaken diagnosis as his text the author discusses the differential diagnosis of acute appendicitis and periodic vomiting due to acetonæmia, which, particularly in slight cases, is apt to be confused with appendicitis. The contrast between the severity of the general intestinal symptoms and the slightness of the local signs is very suggestive of acetonæmia, and as this may be associated with fatty changes in the liver it is obvious why the administration of chloroform is absolutely contraindicated. Since he operated in April, 1918, on the case referred to, the author has never ventured to operate for appendicitis under general anaesthesia when the urine contained acetone, and his systematic examination of the urine for acetone has taught him that even in cases of genuine appendicitis acetonuria is fairly common. The differential diagnosis in such cases is, however, not difficult. If, in addition to acetonuria, the child's breath smells of acetone, and if the clinical picture is dominated by vomiting, and the local signs of appendicitis are not well defined, it is fairly safe to exclude appendicitis. The disappearance of the symptoms within two days' treatment with alkalis should leave little doubt as to the cause of the vomiting. In doubtful cases there is the alternative of appendicectomy under local anaesthesia, with the triple object of verifying the diagnosis, eliminating the risk of a future appendicitis, and saving the child from operation under chloroform at some later date by a surgeon ignorant of this particular danger.

OBSTETRICS AND GYNAECOLOGY.

535. Chemical Investigation of Pregnancy Toxaemias.

DE WESSELOW (*Journ. Obstet. and Gynaec. of the British Empire*, 1922, 29, 1) gives a critical estimate of the value of chemical methods in the investigation of pregnancy toxaemias. He points out that data from chemical examination of the blood and urine during normal pregnancy are scanty, especially regarding the nitrogen partition of the urine. In thirteen healthy pregnant subjects examined when taking 60 to 70 grams of protein daily during the last two months of pregnancy, the blood urea was found to be on the average 17.5 mg. per 100 c.cm. as compared with 20 to 26 mg. in non-pregnant women; this is in accord with Folin's figures. Since in healthy pregnant patients the urea concentration test gives normal results, the low urea content of the blood is not due to increased excretion; possibly it is due to nitrogen retention for purposes of foetal and maternal anabolism. In spite of the low urea-blood content, non-protein nitrogen showed normal amounts; it is therefore unjustifiable to regard a lower ratio of urea to total non-protein nitrogen in the blood of a pregnant subject as pathological. Fibrinogen in the blood plasma showed an increase, being 55 to 100 mg. per 100 c.cm., against 40 mg. in the absence of pregnancy; the increase of fibrinogen during pregnancy has been regarded as a sign of hepatic derangement or as a response to the influence of foreign proteins of placental or foetal origin, and has been quoted as a causative factor in the production of intravascular clotting and eclampsia. The nitrogenous partition in the urine was not atypical; the urinary diastatic index was within normal limits, and the efficiency of the kidney, as judged by the urea concentration test, was not impaired. During labour the urine showed increased ammonia and diminished urea nitrogen (52 per cent. for the latter in one case); diminished protein intake and increased muscular exertion with formation of lactic acid probably are concerned in this. Slight albuminuria was usually present

towards the end of labour. In de Wesselow's twelve cases of pregnancy with mild albuminuria, nine with severe albuminuria, and six with eclampsia, the urea content of the blood was not as a rule greatly increased above that found normally during pregnancy, but the urea concentration test showed a definite fall to be present almost invariably in the concentrating power of the kidney for urea. The writer believes that with respect to prognosis and therapeutic indications the urea concentration test is of greater value than estimation of the nitrogen partition in the blood. The nephritis of pregnancy toxaemias is a combination of the hydraemic and azotaemic types, as shown respectively by the oedema and the impaired urea concentration, and does not differ functionally from the mixed type of nephritis seen in the non-pregnant. Increased blood pressure was found to exhibit much less parallelism with increase of non-protein nitrogen in the blood than with impaired urea concentration as shown by Maclellan's test; the clinical finding that blood-pressure estimations constitute a valuable indication of renal impairment is thus confirmed. In the cases of pregnancy toxaemia the plasma fibrinogen content was notably increased, but this occurs in *B. coli* pyelitis or syphilis complicating pregnancy, as well as in cases of nephritis in the non-pregnant. Changes in the nitrogen partition of the urine which could not be paralleled by those incidental to pregnancy and labour were not usually present, and are to be regarded as less important than the results of the urea concentration test. De Wesselow found that rapid improvement, as shown clinically and by functional tests, followed termination of the pregnancy or intruterine death of the foetus. He suggests that a blood-urea content of more than 40 mg. per 100 c.cm. is an indication for induction, which in the absence of this test may also be considered when the urea concentration test gives a figure below 2 per cent. Repetition of both tests is useful, for rising blood-urea concentration together with falling concentration capacity indicate a progressive lesion.

536. Treatment of Ovarian Carcinoma.

STRASSMANN (*Zentralbl. f. Gynäk.*, April 1st, 1922), having regard to the unsatisfactory results of treating ovarian carcinoma when associated with metastases by simple laparotomy, advocates that at operation extirpation of morbid tissue should be as widespread as possible. When it is possible both adnexa should be removed together with the uterus, and it is particularly important to remove secondary deposits in the omentum; when this has been effected, ascites, which to a greater or less extent always accompanies ovarian carcinoma, is said not to recur. The prognosis of these cases has improved since in late years post-operative x-ray treatment has been given; of the author's 17 cases so treated 4 survived two and 2 survived six years. SCHÄFER (*Ibid.*) had a primary mortality of 17 per cent. and a similar percentage of from five to ten years' cures in a series of 70 cases operated on for primary ovarian cancer; of 25 cases of unilateral ovarian cancer a cure was obtained in 40 per cent.

537. Indications for Vaginal Caesarean Section.

PHANKEU (*Boston Med. and Surg. Journ.*, April 13th, 1922) has found indications for vaginal Caesarean section in cases in which cervical rigidity failed to be influenced by introduction of a dilating bag; in cases of eclampsia in which *anconeum* force was indicated or in which dilatation by means of a bag was found impracticable; in cases of pregnancy toxaemia of the non-convulsive type, characterized by premature placental detachment or by grave prognostic signs, such as amblyopia or persistently and increasingly high blood pressure; in severe cases of pyelitis; and in cases in which removal of a macerated foetus is indicated—for example, by advanced maternal pulmonary tuberculosis, or by reason of the patients having only one kidney. Except in one instance, he has performed the operation from the fourth to the eighth month of pregnancy; it is described as the ideal procedure when, before the ninth month, there is an indication for immediate delivery in a patient with a long, rigid, undilated cervix. Before term, it is not usually necessary to incise the cervix behind. The operation is followed by comparatively few symptoms of disordered nutrition.

538. Brow Presentations.

ACCORDING to EYMER (*Zentralbl. f. Gynäk.*, April 29th, 1922) persistent brow presentation occurred thirteen times in 10,000 labours at the Heidelberg clinic. In two cases each, contracted pelvis, pendulous abdomen, or twin birth was concerned etiologically. The average duration of labour was seventy-nine hours, and birth took place spontaneously in six instances, in half of which the child was born alive. The operative procedures found necessary were osteotomy in three instances, Caesarean section in one, perforation in one, and forceps delivery in two. There was no maternal mortality

and the foetal mortality (two syphilitic cases being excluded) was unusually low—namely, 11 per cent. A conservative attitude is recommended with regard to treatment. Prophylactic correction is not recommended; it is fraught with considerable maternal risks, and is only applicable in early stages at a time when spontaneous correction may ensue. Caesarean section is not justifiable except in cases in which it is indicated on maternal or foetal grounds, which are independent of the existence of the brow presentation. Spontaneous birth of a living child after protracted labour was observed in two cases in which before admission to the clinic fruitless endeavours to deliver by forceps had been made. SEITZ (*Ibid.*) records thirteen cases from the Giessen clinic without maternal or foetal mortality. This exceptionally favourable record is quoted in support of expectant treatment, but it is admitted that in cases of contracted pelvis, which predisposes to brow presentation and complicates its management, delivery although possible in occipito-posterior presentation, may be impossible *per vias naturales* in brow presentation.

539. Syphilis as a Cause of Foetal Malformations.

HENROTAY (*Gynéc. et Obstét.*, 1922, v, 4) believes that syphilis is more commonly the cause of foetal malformations than is usually supposed. He quotes as examples a case of ectopia of the abdominal viscera with bilateral talipes and pina bifida, one of cephalocele combined with meningocele, one of hydatidiform mole, and one of harelip and cleft palate; the mothers in all cases were free from manifest syphilitic stigmata, but their blood serum showed one or other of the biological tests to be positive (Hecht's or Levaditi's being sometimes positive when the Bordet-Vassermann was negative). The case is also related of two sisters-in-law of whom one had successive pregnancies giving rise respectively to stillbirths of macerated foetuses (one with cranial deformity), two living children successively, and a child suffering from pemphigus and later developing signs of congenital syphilis; the other gave birth in her first pregnancy to an anencephalic monster. Serological tests showed syphilitic infection (afterwards proved to be hereditary) of each of the fathers concerned; in the mothers the Bordet-Vassermann test was negative, but other tests were positive. Antisyphilitic medication was instituted both in a third brother and in his wife, who was in her first pregnancy; both parents showed a positive Hecht's reaction.

PATHOLOGY.

540. Adrenaline and Shock.

RICE (*Bull. of the Johns Hopkins Hosp.*, March, 1922) has made a study of the relation of the adrenal glands to experimentally produced shock for the purpose of testing the truth of the statement that shock may be due to disordered function of the adrenals—a widely current conception based on the facts that epinephrin injected intravenously has such a remarkable effect on blood pressure, whereas removal of the adrenals brings about a condition of hypotension similar to that found in shock. Anaesthetized cats were subjected to shock-producing trauma, and the time taken for the blood pressure to fall to 60 mm. and the symptoms of shock to appear were recorded. Similar experiments were carried out on animals whose adrenals had been previously removed by the extra-peritoneal route, and the following results were obtained. The time required for the production of shock and the character of the blood-pressure curves was the same in animals whose adrenals had just been removed as in normal controls, which proves that disordered adrenal function is not a factor in the production of shock. On the other hand, the blood pressure of the adrenalectomized animal begins to fall about four hours after the adrenals are removed, and within the first twelve hours after adrenalectomy the blood pressure in the unanaesthetized animal invariably falls to a very low level and progressively declines until death. This fall in blood pressure is independent of operative trauma and begins before asthenia has appeared, which suggests that the adrenals are concerned in the maintenance of the blood pressure at the normal level. With regard to the influence of the anaesthetic it was found that animals which were kept lightly anaesthetized with ether for an hour immediately before the abdomen was opened were very resistant to the shock-producing effect of intestinal manipulation. On the other hand, if identical intestinal manipulations were commenced immediately after anaesthetization then symptoms of shock appeared more rapidly. This protective effect of preliminary ether anaesthetization was met with repeatedly, but once the blood pressure had commenced to decline ether anaesthesia had a distinct tendency to hasten the onset of shock. The author could find no evidence that cardiac failure is a factor in the

production of shock, or that failure of the vasomotor centre is a primary factor in shock. The cardio-inhibitory centre was shown to respond to stimuli and also to function independently in deep shock.

541. Apparent Increase of Tubercle Bacilli in Sputum undergoing Putrefaction.

ACCORDING to BEZANÇON, MATHIEU, and PHILIBERT (*C. R. Soc. Biologie*, March 25th, 1922), it was found that if tuberculous sputum be placed in a test tube and incubated at 37° C. for twenty-four hours to four days, there is a progressive increase in the number of tubercle bacilli which can be demonstrated in a slide preparation. This increase is confined to the clot at the bottom of the tube. After allowing putrefaction to proceed for from four to seven days a diminution in the number occurs, till after a period of about six weeks no more bacilli are to be found. The most favourable time for examination appears to be at the end of four days, for then as many as ten to fifty times the number of bacilli can be demonstrated, as can be seen by direct examination without previous incubation. That an actual increase in the bacilli occurs is regarded as improbable, since animal tests are only positive for about two days, showing that in all probability the bacilli die out fairly rapidly. What actually takes place is that the autolysis and liquefaction of the sputum allows the bacilli to settle and collect in greater numbers at the bottom of the tube. Comparing this method with that of homogenization, it is found that nearly 9 per cent. of sputa, when subjected to the latter method, are positive when putrefaction technique. The main advantage of the method seems to be in the larger quantities—10 to 20 c.cm.—of sputum which can be dealt with, thus increasing the chances of obtaining a positive result.

542. Rhinoscleroma.

PARDO-CASTELLO and DOMINGUEZ (*Arch. of Derm. and Syph.*, April, 1922) have had the opportunity of examining histologically and bacteriologically material removed from an advanced case of rhinoscleroma. This disease is common in eastern Europe but is rare in America, and this is the first case reported there in a person who had never been abroad; she was a negress living in Havana. Clinically it was observed that the right nasal cavity was filled with a reddish mass, obstructing the breathing and tender on pressure; the mass was dark red and covered with a thin epidermis that wrinkled when the tumour was taken between the fingers; there was no ulceration or bleeding, but when a portion of the tumour was removed by biopsy the haemorrhage was profuse but easily stopped. Histological examination showed the tumour to be a typical granuloma with the occurrence of vacuolated cells of Mikulicz and plasma cells in hyaline degeneration—a characteristic picture in rhinoscleroma. Bacteriological examination failed to show any evidence of the presence of the different organisms to whose influence this disease has been attributed in the past. On the other hand, there was demonstrated within the tumour cells, and recovered by culture, a Gram-negative bacillus which, from its biological characters, proved to be a member of the *B. lactis aerogenes* group. Cultures of this organism produced an intense febrile reaction and inflammation when injected into guinea-pigs, but failed to reproduce rhinoscleroma.

543. The Pathology of Diabetes Insipidus.

A CONTRIBUTION to the study of this interesting disease is made by CAMUS, ROUSSY, and LE GRAND (*C. R. Soc. Biologie*, April 1st, 1922), who report the results of the pathological findings of a case which came to autopsy. During life the patient had suffered from epileptiform crises, transient paralyses, and a polyuria of 7 to 8 litres per diem. The cerebro-spinal fluid showed a slight lymphocytosis and increased albumin; the Wassermann reaction was negative. Treatment was without avail, and he died after a severe attack of headache and vomiting. *Post mortem*, a small abscess was found in the sella turcica, replacing the whole of the pituitary body; the rest of the brain appeared macroscopically to be normal. Histological examination, however, of serial sections passing through the optic-peduncular region revealed marked lesions of an inflammatory and degenerative nature at the level of the paraventricular nuclei. Both sides were affected. Small foci of perivascular haemorrhage, infiltrated with polymorphonuclear leucocytes, were encountered, while the surrounding nerve cells were in a state of chromatolysis, with peripheral displacement of the nucleus and vacuolation. These findings are in accord with observations reported on other cases, and lead the authors to suggest that the origin of the polyuric syndrome should be placed not in the pituitary, but in the grey matter of the nuclei of the infundibulum and the tuber cinereum—an hypothesis which is supported by a considerable amount of experimental evidence.

A British Medical Association Lecture

ON
HYPERTHYROIDISM.*

GEORGE R. MURRAY, M.D., D.C.L., F.R.C.P.,

PROFESSOR OF SYSTEMATIC MEDICINE IN THE VICTORIA UNIVERSITY AND
SENIOR PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

In the great majority of chronic diseases we are called upon to recognize and remedy deficiencies of function resulting from morbid changes in individual organs. These structural changes may produce alterations in the size of the organ involved which may have mechanical effects—as, for example, retention of urine due to enlargement of the prostate gland. Mechanical effects of this kind are, however, in many cases of less importance than the functional disabilities. We have been apt in the past to pay great attention to both gross and minute changes in structure without fully appreciating their effects upon functional efficiency. We are learning by degrees to estimate more accurately the changes in function in a diseased organ and to realize their importance. Professor Hugh Maclean¹ has shown how this may be done in the case of the kidney by methods which are applicable in practice and, when taken into consideration along with the symptoms, afford valuable information as to the extent of impairment of function in cases of renal disease. In diseases of the endocrine glands we have to consider the results not only of changes in their size and shape, but also of alterations in their functional activity which may be either exalted or depressed. Enlargement of an endocrine gland may produce important effects owing to its anatomical position. Thus owing to its confined position a comparatively moderate enlargement of the pituitary gland may produce the serious pressure effects known as “neighbourhood” symptoms, which occur in some cases of acromegaly. In medicine we are more directly concerned with the results of changes in functional activity, which may be either greater or less than normal. The results of too great functional activity are, in the case of the thyroid gland, only too well seen in cases of Graves's disease. The dire results of loss of function in the case of the suprarenal glands are familiar to all in the form of Addison's disease.

In a former British Medical Association lecture² a general account was given both of the methods of ascertaining, as far as possible, the physical condition of the endocrine glands and of the symptoms which are due to changes in their functional activities. On this occasion the varieties and results of glandular overactivity, as illustrated by the thyroid gland, will be considered as well as the principles which should guide us in our endeavour to relieve them. Overaction of a secretory gland is in the first instance probably due to nervous influence. The effect of fear in arresting the action of the salivary glands is a familiar example of inhibition of secretion, whereas salivation at the sight of food illustrates the results of nervous stimulation. In the case of the thyroid gland hypersecretion in the first instance is probably due to nervous overstimulation, though stimulation by chemical messengers brought by the blood is also possible. Later on definite changes in size and structure enable the gland to maintain for months, or even years, the increased activity which is now generally known as hyperthyroidism.

The cases in which hyperthyroidism is a prominent feature may conveniently be divided into three groups:

1. Simple hyperthyroidism.
2. Toxic adenoma of the thyroid gland with hyperthyroidism.
3. Exophthalmic goitre or Graves's disease.

There is no hard and fast division between these groups, but the great majority of cases in which symptoms of hyperthyroidism are present fall into one or other of them. In hyperthyroidism there is an overproduction of the normal thyroidal secretion which contains its hormones. It is possible, though not yet proved, that the secretion in some cases is not only increased in quantity, but is also altered in quality, so that there may be dysthyroidism as well. There is good reason to believe that “thyroxin,” which has been isolated by Dr. Kendall, is the chief, if not the only active hormone secreted by the gland. This substance, he has shown to be tri-hydro-tri-iodo-alpha-oxy-indol propionic acid

($C_{11}H_{10}O_3N_1I_3$). It is present in very small quantities, as two tons of fresh thyroid glands only yield 18 grams or 280 grains of thyroxin.

The most marked hyperthyroidism is seen in fully developed cases of Graves's disease. Here the microscopical changes in the gland are indicative of great secretory activity. The cells lining the alveoli are columnar instead of cubical, and the wall of the alveolus becomes plicated so that the secreting surface is increased while the colloid is changed in appearance. Similar but slighter changes in the gland can be produced experimentally. If part of the gland in the monkey is removed the remainder becomes more active as a compensatory change. A section of part of the right lobe of the thyroid gland of a rhesus monkey from which I removed the whole of the left lobe and part of the right lobe fourteen months before it was killed, shows similar changes in lesser degree, such as probably occur in the milder forms of hyperthyroidism in man.

Recent determinations of the basal metabolic rate, especially by Dr. W. M. Boothby³ of Rochester and by Dr. J. H. Means⁴ of Boston, have enabled the different degrees of hyperthyroidism to be measured in percentages, and it is claimed that the results are as valuable an indication of thyroidal activity as the readings of the thermometer are of the course of a fever. This determination takes a good deal of time, and has not as yet been extensively employed in this country. In hyperthyroidism there is an increased production of heat which may be estimated by indirect calorimetry. By this method the determination of the carbon dioxide production or of the consumption of oxygen gives information from which the basal metabolic rate can be calculated, and stated in percentages above or below an average normal rate. It has been found that in mild forms of myxoedema the basic metabolic rate is from -20 per cent. to -40 per cent. of the normal. Slight forms of hyperthyroidism have a metabolic rate from +20 per cent. to +40 per cent.; moderate cases of Graves's disease from +40 per cent. to +60 per cent., severe cases from +60 per cent. to +100 per cent.

As the result of more than 2,500 observations, on about 1,200 subjects A. Peterson and W. Walter⁵ have shown that there is a general relationship between the pulse rate, taken in the resting and fasting condition required for determining basal metabolism, and the metabolic rate. As the basal metabolism increases from normal to +40 per cent. the pulse rate increases from 80 to 110. In determining this general relationship, cases in which there is cardio-vascular disease or other obvious cause of tachycardia are omitted.

The determination of the basal metabolism at regular intervals affords a useful indication of the progress of the patient under treatment. It has been shown by E. M. and D. Wilson that in a case of myxoedema under treatment the rate rises from -41 per cent. to -10.1 per cent., and in Graves's disease rest in bed for a month may cause a fall in the rate from +42 per cent. to +25 per cent. We are thus furnished with a method of measuring the severity of the malady and of recording the progress under treatment month by month on a chart, much in the same manner as the course of a fever is recorded day by day. In many cases these observations show that roughly the pulse rate varies directly, while the weight varies inversely with the metabolic rate. This is important, as it indicates that when the metabolic rate cannot be measured the variations in weight and pulse rate are useful indications as to the progress of a malady due to changes in the functional activity of the thyroid.

The changes in metabolism are still further illustrated by two of my cases of myxoedema and exophthalmic goitre in which a detailed analysis of the urine passed in twenty-four hours was made by Dr. C. Powell White before and after treatment. The patients were taking ordinary hospital diet, and the findings are of interest more in their comparative than their absolute values.

A woman, aged 39, was admitted to the Manchester Royal Infirmary suffering from well-marked myxoedema. A sample of the twenty-four hours' urine was taken for examination on March 17th, 1920, before treatment was commenced. The patient was then given one 2½ grain thyroid tablet a day. On March 24th the dose was increased to 5 grains, on April 9th to 10 grains, and finally, on April 22nd, to 15 grains a day. The symptoms steadily diminished, and had practically disappeared when another sample of the urine was taken on May 7th, after treatment for fifty days.

Dr. White found the amount of nitrogen from urea was increased from 3,501 mg. a day in the first sample to 6,948 mg. a day in the second, or to almost exactly double the amount. The nitrogen from ammonia, creatinin, and uric acid was

[3206]

* Delivered to the Worcestershire and Herefordshire Branch.

also increased, the total nitrogen being increased from 5,208 to 8,444 mg. a day. This gives an indication of the increased metabolism under the stimulating effect of the thyroidal hormone.

The second case was that of a girl, aged 19, who was admitted to the Royal Infirmary on January 29th, 1920, with well-marked Graves's disease. The pulse rate varied from 98 to 120. She was kept at rest in bed and had two doses of α rays before the first sample of urino was collected on February 10th. Between this date and March 2nd, when the second sample of urine was taken, she received seven doses of α rays. The goitre and the exophthalmos both diminished a little, and the pulse rate fell to 96 but increased again to 108, and she lost 7 lb. in weight.

It is of interest to note that during this interval the urea nitrogen diminished from 7,550 to 2,744 mg. a day—that is, to nearly one-third of the former amount. The nitrogen from ammonia, creatinin, and uric acid had also diminished. The total nitrogen fell from 10,819 to 4,390 mg.—that is, to considerably less than one-half. As far as they go, these findings indicate the fall in metabolism which may occur in Graves's disease under the influence of rest and α -ray treatment.

The three clinical varieties of hyperthyroidism already mentioned will next be considered separately.

1. Simple Hyperthyroidism.

In this condition there is a slight uniform enlargement of the thyroid gland similar to that which occurs in the simple parenchymatous goitre of puberty, but it is accompanied by symptoms of hyperthyroidism. The pulse rate is accelerated and may be from 90 to 120 a minute. There is mental alertness, with agitation in some cases, and a fine tremor of the extended hands is visible. The skin is warm, and may be moist. There are no eye symptoms. This condition corresponds to what used to be described by French writers as the *formes frustes* of Graves's disease. Fatigue is easily induced, but many patients are still able to carry on their usual occupation. The metabolic rate may be increased to over +60 per cent. In these cases early and prompt treatment is most important. Untreated, the symptoms are apt to become more marked, and some of the cases pass on into fully developed Graves's disease.

Surgical treatment is not required. Rest in bed for a week or two or longer according to the severity of the symptoms is followed by marked improvement and a fall takes place in the metabolic rate. Prolonged rest in bed is not required in these cases, and in the milder forms of the malady it is sufficient to ensure that ten to twelve hours are spent lying down. Medicinal treatment is useful and a prolonged course of arsenic in small doses of from 3 to 5 minims of Fowler's solution is often beneficial. If there is much excitability bromides may be given with the arsenic in small doses. Quinine hydrobromide in doses of 3 to 5 grains is also valuable and may be given alone or with arsenic. X-ray treatment is more reliable than any medicinal treatment in these cases. Details of this vary according to circumstances. A full dose may be given twice a week for the first few weeks and then once a week, the amount and frequency of the dosage being regulated by the progress, and it is advisable to give a few doses at lengthened intervals at the end of the course rather than to end it abruptly.

2. Toxic Goitre with Hyperthyroidism.

In this condition a goitre which may be either parenchymatous or adenoparenchymatous has usually been present for several years without causing any general symptoms. At the end of this quiescent period, which may be as long as ten years, the gland begins to show signs of overactivity. This may be the result of some sudden emotional shock or accident, or it may follow a prolonged period of nervous strain. The goitre may or may not be further increased in size. The symptoms of hyperthyroidism are those we have already considered, but they may become severe and all the symptoms of Graves's disease may appear—a variety of the malady which has also been described as secondary Graves's disease.

If such an increase in the size of the goitre takes place as to cause pressure on the trachea, clearly operative treatment must be adopted. In cases in which there are no pressure signs the indications are not so clear. My own view is that these cases of toxic adenoma should be treated by operation if the goitre is large, and especially if it is an adenoparenchymatous or cystic goitre, as soon as marked symptoms of hyperthyroidism appear. The extent and character of the operation must be adapted to the needs of the case. Removal

of one lobe is apt to leave displacement of the trachea by the lobe which is left. Bilateral partial resection seems best to meet the needs of these cases. If operation is declined, or the condition of the patient prevents operation, treatment of the hyperthyroidism must be carried out on the lines already described. Improvement will take place, but the goitre is not appreciably diminished in size and the results are not very satisfactory.

3. Exophthalmic Goitre.

The symptoms of this malady are so well known that no description is necessary. In the treatment of fully developed Graves's disease we are faced by a difficult problem. Opinions differ widely as to the relative merits of medical and surgical treatment. I shall therefore endeavour to give shortly the results of personal experience. With regard to medical treatment all that I have already said about the treatment of simple hyperthyroidism holds good in the case of Graves's disease, though the greater severity of the symptoms entails a stricter régime. At first complete rest in bed in moderate and severe cases is essential, and may have to be continued for several weeks or even months.

The question of the influence of diet in the treatment of this malady is of importance owing to the work of Chalmers Watson, McCarrison, and Professor and Mrs. Mellanby. It has been shown by Chalmers Watson that a meat diet produces changes in the thyroid gland in animals suggestive of hyperthyroidism. Colonel McCarrison⁶ has shown that excess of fats or of unsaturated oleic acid in the diet may cause a relative deficiency of iodine and enlargement of the thyroid gland, and it has been suggested that fats should be reduced in these cases. Professor and Mrs. Mellanby⁷ found in their work on experimental rickets that when butter was included in the diet a fivefold increase in the size of the thyroid took place, the hyperplasia in some cases affecting chiefly the secretory cells of the alveoli, and in others the intervascular cells. Increasing the fat in the diet of puppies from 10 to 20 grams intensified the change, and on a diet containing 20 to 25 grams of butter the weight of the thyroid gland was found to be fourteen times the weight of the gland in puppies which were fed on cod-liver oil instead of butter, and in which no increase in the size of the gland took place. They have found that in cases of Graves's disease the addition of butter intensified the tachycardia and nervousness, and was followed by loss of weight. They advocate, therefore, a diet of separated milk powder, porridge, bread, green vegetables, eggs, and lean meat, with 15 c.c.m. of cod-liver oil each day. I have usually advised the exclusion of red meat and their extractives from the diet. On the other hand, I have given fats, especially if there is loss of weight, in the form of milk (up to three or four pints), cream, butter, and animal fats. I also allow fish, eggs, bread, vegetables, and fruit. It is evident that further investigations are required to ascertain the most suitable diet in these cases, as it does not necessarily follow that a diet which induces hypertrophy of the gland in healthy animals is unsuitable for the treatment of Graves's disease in man.

With regard to medicinal treatment, the special organic preparations such as rotagen, antithyroidin, or thyroidectin, have not given any specially good results. Milk of a thyroidless goat has, however, been helpful in some cases, but it is difficult to obtain and hardly worth the trouble and expense entailed. Of drugs, arsenic, bromides, belladonna, convallaria, and quinine hydrobromide are the most useful.

X-ray treatment has proved to be of great value, and there can be no doubt as to its power to reduce the activity of the gland. This was clearly shown in a case recently recorded by Mr. H. Stratford,⁸ in which radiation of the scar and supraclavicular region for a year after removal of the breast for carcinoma had induced such extensive atrophy in a previously healthy thyroid gland that the patient developed myxoedema. The amount and frequency of the dose and the total duration of the treatment must be adapted to the needs of each case. The treatment may be continued for six months or a year, or even longer if improvement is taking place. As a fair example the following case may be mentioned:

Miss W., aged 36. When seen on January 18th, 1918, she had a slight goitre which had been present for about three months. There was exophthalmos, with tremors and loss of hair, and the pulse rate was 140. X-ray treatment, which had been given twice a week from December 14th, 1917, was continued till September, 1918. It was then continued once weekly till May, 1919. Steady improvement took place, as is shown by the increase in weight

from 8st. 10lb. on March 2nd, 1918, to 12 st. 11 lb. in May, 1919, and to 13st. 21lb. in October, 1920—a gain of 4st. 6lb. When seen last, on February 3rd, 1922, she had been steadily at work as a school teacher since May, 1919. She occasionally has palpitation, but is otherwise well, the pulse rate being 88.

In this case the treatment occupied seventeen months, during which she received about 100 doses of x rays. Dr. Barclay informs me that on an average some twenty-five doses are sufficient to produce a good result. It is, however, quite worth while to continue the treatment up to one hundred doses if necessary.

Dr. A. E. Barclay and Dr. Woodburn Morrison have treated many of my cases, and by the kindness of Dr. Morrison I am able to give you the general results which followed this treatment in one hundred consecutive cases of exophthalmic goitre treated by them with x rays. In some seventy of these cases this treatment was carried out on my advice. Of these cases, 82 were women and 18 men. In 4 men and in 17 women the symptoms were mild; in 9 men and in 34 women they were of medium severity; and in 5 men and in 31 women severe. In the men the duration of treatment was from five months to two years in the mild cases, from three months to three years in the medium cases, and from one to four years in the severe cases. In the women the treatment lasted from five months to two years in the mild cases, from six months to four and a half years in the medium cases, and from six months to five years in the severe cases. The condition of these cases after treatment is briefly shown by dividing them into three classes. In the first class are placed only those in whom complete recovery has taken place; thus 2 mild and 2 medium cases in men, 8 mild, 7 medium, and 8 severe cases in women, or 27 per cent. in all, completely recovered. In the second class are grouped all the cases in which a good functional result was obtained—that is to say, those cases in which, although some symptoms still persisted, such marked improvement had taken place that a living could be earned and a normal life could be lived. This result was obtained in 11 men, 2 being mild cases, 6 of medium severity, and 3 severe cases; 38 women were placed in this class—8 slight cases, 20 of moderate severity, and 10 severe cases; so that altogether a good functional result was obtained in 49 per cent. The third class contained those who continued the treatment but only showed slight improvement: two men, one being a medium case and the other a mild one, and 17 women—1 mild, 6 medium, and 10 severe cases—came into this group, making 19 per cent. The remaining four women gave up the treatment without showing any improvement.

It is extremely difficult to assess fairly the results of medical treatment in a disease such as exophthalmic goitre. In the opposite condition of myxoedema the value of treatment is at once evident because we are dealing with a malady which, before I first suggested and introduced the treatment by thyroid extract thirty-one years ago, inevitably got worse and ended in death; whereas under treatment health is now regained and life can be prolonged to its normal limit. Exophthalmic goitre in a certain proportion of cases tends to improve and even disappear under any rational line of treatment or even without it. Different series of cases have shown the following results. The course of exophthalmic goitre under medicinal treatment has been described by several writers. Dr. H. Mackenzie⁹ gives a table of 33 cases combined with 24 cases recorded by Dr. R. T. Williamson, in the Manchester Royal Infirmary. Of these 57 cases, 14 died and 10 recovered completely, which gives a complete recovery of 17.5 per cent. and a mortality of 24.5 per cent. Of 169 cases admitted into Guy's Hospital during 1888-1907 (both inclusive) collected by Sir William Hale-White,¹⁰ 75 were accounted for. Of these, excluding cases which were operated on, there were 67, of whom 26 were dead, whereas among 53 private patients only 7 died. Dr. J. H. Campbell,¹¹ who collected the cases treated at the same hospital between 1908 and 1917, was able to trace 89 out of 127. Dr. Campbell gives his results in round figures as: almost cured, 40 per cent.; very much improved, 30 per cent. (these 70 per cent. would correspond to the two first classes of Drs. Barclay and Morrison's tables); died, 15 per cent.; not much improved or worse, 15 per cent.

Broadly speaking, then, under the influence of rest and medicinal treatment some 25 per cent. of cases are fatal, a similar percentage recover, and the remaining 50 per cent. improve to a greater or less extent. Returning to the group of 100 cases treated by x rays, as far as I know, all are living, and we see that 76 per cent. either recovered completely or regained good functional activity suitable for ordinary life.

It may fairly be claimed that more cases recover and that the period of disease or invalidism is materially shortened under x-ray treatment than without it. The risk of causing myxoedema by too much radiation is small, but it has occurred in one case which I have seen. I have, however, seen myxoedema follow recovery from exophthalmic goitre without the use of x rays, and other similar cases have been recorded.

In some of my cases, and especially in those residing at a distance, radium has been used, the applications being usually made once every six weeks. This treatment appears to be unsuitable for very severe or acute cases, as the primary effect may be to temporarily increase the hyperthyroidism. In one acute case which was under my care in the Manchester Royal Infirmary the first application of radium was followed by a rapid exacerbation of the symptoms and the patient died. Dr. E. S. Reynolds informs me that he knows of two sisters who both died under similar circumstances. In many cases good results are obtained, and the following may be given as a fair example of the effects of this treatment.

A man of 25 was seen in June, 1919. He had a small goitre, slight exophthalmos, tremors, nervousness, and a pulse rate of 136. He had seven or eight doses of radium in the course of a year. When last seen in February, 1922, he was feeling well, and had been able to undertake the work of a secretary to a company. He had gained 2 st. in weight. The pulse was 70 in bed, 80 when up at home, but it was 120 when he came to see me.

Dr. A. Burrows¹² has recently tabulated the cases of exophthalmic goitre treated with radium at the Manchester and District Radium Institute during the years 1915-19. During this period 180 cases were treated. His conclusions are as follows: "Fifty-two of these cases are recorded as cured—that is to say, all symptoms and signs of disease have disappeared, except sometimes some slight exophthalmos, for over two years, and only one recurrence is recorded. Many cases have already when they come for treatment definite myocardial failure, which may persist, and although the hyperthyroidism is cured they cannot be recorded as cured cases. The application of radium is a prolonged process, and much patience is needed because the treatment may last from two to three years." Five cases were well for six months or more, but had not been recently traced. If these cases are included we find that 31.6 per cent. recovered under radium treatment. The remaining 122 cases are all returned in one group as improved, not improved, or died, so that we are unable to compare the results, as far as improvement is concerned, with those obtained by x-ray treatment, and the number of deaths is not recorded.

Surgical Treatment.

In adopting surgical treatment in exophthalmic goitre we endeavour to effect a rapid reduction of the overactivity of the gland to a normal level by the removal of a sufficiently large amount of the secreting tissue. This may be achieved by ligation of the superior arteries, followed by a subtotal thyroidectomy at a later stage, or the thyroidectomy may be done forthwith. My early experience of operation was unfortunate, as the first three cases all died. The mortality is now stated to be from 2 to 5 per cent. In mild cases operation is not required; in cases in which the trachea is compressed it is essential. It is in moderate and in severe cases that opinion is divided. In any case, medical treatment should have a full trial for six months; if no improvement has then taken place operation should be considered. The most suitable cases are those in which the goitre is of considerable size, as they do not do well under medical or radiological treatment.

Briefly, the advantages of operation are:

1. The saving of time by the rapid reduction of the hyperthyroidism and relief of the symptoms.
2. The diminution of the risk of irreparable damage to the heart in the form of the chronic myocarditis which develops in severe and in prolonged cases.
3. The complete and rapid recovery in some cases.

The disadvantages are:

1. The risk to life.
2. The uncertainty of the ultimate result owing to the difficulty in determining the right amount of the gland which should be removed in each case. For example, one of my cases had two partial thyroidectomies performed, but at the end of ten years still showed marked symptoms of the malady, which finally subsided under x-ray treatment.
3. The tendency to recurrence at the end of a year.

As an example of a successful operation advised under special circumstances the following case may be mentioned:

Mrs. M., aged 27, seen on February 14th, 1921. A goitre had first appeared eighteen months before; this was followed by dyspnoea on exertion and occasional palpitation. She had a moderate uniform enlargement of the thyroid gland with tremors of the hands. The pulse rate was 150 and the cardiac impulse extended two fingerbreadths outside the left nipple line. There was exophthalmos. As this patient wished to go to China as soon as possible with her husband to reside in a district some 7,000 ft. above sea-level, and was about to visit relations in Minnesota, I advised her to go to the Mayo clinic for operation. In June last the basal metabolic rate was *plus* 40, when Dr. Verne C. Hunt of Rochester did a ligation of both superior thyroid vessels. After this she gained 20 lb. in weight and improved in general condition, but the basal metabolic rate was *plus* 45. Dr. Hunt has kindly informed me that on September 6th a double resection of the gland with removal of the isthmus was done. She had an uneventful convalescence and was able to go to Japan in November. The latest report received from Mrs. M. in Japan stated that she was perfectly well. I advised early operation in this case owing to the special circumstances already mentioned, and the result has been most satisfactory.

A PULMONARY SIGN IN ACUTE INFECTIONS OF THE BILIARY TRACT.

BY

D. P. D. WILKIE, M.Ch., F.R.C.S.,

ASSISTANT SURGEON, ROYAL INFIRMARY, EDINBURGH.

Most medical men are familiar with the deceptive abdominal symptoms and signs which may sometimes dominate the clinical picture in the early stages of pleuropneumonia. Most can recall mistaken diagnoses as well as the feeling of satisfaction which has followed a successful detection of the trouble above the diaphragm and the sparing of the patient an abdominal exploration both unnecessary and fraught with risk. On the other hand, I find that very few are familiar with the converse picture—namely, the case presenting pulmonary symptoms and signs in which the primary and focal lesion is in the upper abdomen.

That acute infections of the gall bladder and bile ducts are frequently associated with definite physical signs at the base of the right lung is a fact I have repeatedly observed; in a number of cases it has led to an incorrect diagnosis, a primary lung lesion being suspected and the pain in the right hypochondrium being regarded as referred from the pleura.

My attention was first directed to this sign some ten years ago by the case of a gentleman on whom I had operated for inguinal hernia:

Mr. T. D., aged 65, was operated on (December 15th, 1912) for a right inguinal hernia. Four days later (December 16th) he complained of severe pain on the right side of his chest and in the right hypochondriac region of the abdomen; temperature 100°, pulse 90, respirations 26. There were very definite tenderness and rigidity just below the right costal margin, and a deep inspiration caused great pain in this region. I made a diagnosis of acute cholecystitis probably associated with gall stones, and recommended the local application of heat. At the request of his relatives a physician was called in to see him, and he discovered that there were numerous crepitations at the base of the right lung, and diagnosed congestion of the right base with referred abdominal pain. Two days later a definite tinge of jaundice appeared, and the original diagnosis received strong support. In a week the infra-costal pain and tenderness had subsided.

In January, 1914, I was called to see the patient again. He had had three attacks similar to that described above, and in this, the fourth, attack the symptoms were much more urgent than ever before. I operated and found a partially gangrenous gall bladder, containing pus and over 100 calculi.

Since then I have made a habit of examining the bases of the lungs in cases of acute biliary infections, and have found that crepitations at the right base occur in quite a fair percentage of cases. The following case illustrates the importance of recognizing the significance of this physical sign:

Mrs. F., aged 53, was operated on for gall stones on November 10th, 1920. She gave a typical history of recurrent attacks of gall-stone colic extending over a period of five years. At the operation ten gall stones were removed from the gall bladder, which was

drained. She left hospital at the end of four weeks with the wound healed. Five days after leaving hospital she had an attack of pain round the right side of the chest. Her doctor found crepitations and some pleural friction at the right base, and gave the opinion that this was a chest condition and not connected with the biliary tract. The patient, however, insisted that the pain was the same as she had had before operation. At intervals of a few weeks the attacks recurred; always accompanied by the basal pulmonary signs, and she had poultices applied round the right side of the chest.

On January 16th, 1921, she had a very severe attack, again with crepitations, but this time also with very acute tenderness in the right hypochondrium. Poultices over the right base gave no relief, and after a few days she had a definite tinge of jaundice. Her doctor diagnosed cholecystitis and sent her into hospital. A swelling was found in the right breast, and a swelling in the neck on pressure in this region. Numerous fine crepitations could be heard, and there was slight dullness on percussion. On January 19th, 1921, she was again operated on. The gall bladder, greatly enlarged and thickened, containing mucopus and one faceted calculus plugging the cystic duct, was removed. Since the second operation she has been entirely free from biliary and pulmonary symptoms.

This pulmonary sign may also be found where the infection is located in the ducts and where the gall bladder is not the chief seat of trouble, as the following case shows in a most instructive manner:

Mr. D., aged 67, had suffered for over a year from frequently recurring attacks of pain and discomfort in the epigastrium, accompanied by rigors and always followed by a faint tinge of jaundice. The pain was never very severe, but in each attack he felt ill, had a temperature of 100° to 101° F., and was confined to bed for several days—the latter mainly because his doctor always found signs of congestion at the base of the right lung. On several occasions the question of operation was discussed, but it was doubted whether it was justifiable on account of the pulmonary symptoms. Latterly the attacks recurred so jaundice though slight became so constant, operation. His doctor noted in each attack right base, none at the left.

Operation (January 9th, 1921).—A very large and somewhat thickened gall bladder was found. It contained no calculi. The common duct was very dilated and thick-walled, the head of the pancreas was hard—the seat of chronic interstitial pancreatitis. The common duct was opened and a large quantity of granular debris and bile-sand scooped out. No calculi of any size were present. A probe passed readily into the duodenum. The common duct was drained, and in view of the sclerosing pancreatitis a cholecysto-duodenostomy was performed. The patient made an uneventful recovery, rapidly put on weight, and a year later reported that he had been entirely free from all biliary and pulmonary trouble.

The interesting point in regard to this case was the fact that the pulmonary signs accompanying his recurring attacks of cholangitis were for a time regarded as a contraindication to operation, and had no jaundice been present even more emphasis would certainly have been laid on the pulmonary as opposed to the biliary symptoms.

Etiology of the Pulmonary Congestion.

Three possible explanations for this must be considered:

(1) The infection in the gall bladder or bile ducts spreads by way of the peritoneum through the lymphatics of the diaphragm and so reaches the pleura and the base of the lung. Facts which favour this theory are that in two cases, besides the crepitations, pleural friction was detected over the right base, and in another case a well-marked pleurisy with effusion was present within twenty-four hours of the operation for removal of the infected gall bladder.

(2) That reflexly, from irritation of the sensory fibres of the phrenic nerve, the diaphragmatic excursion on the right side is diminished, the expansion of the base of the right lung is restricted, and some hypostatic congestion results. There can be no doubt that this factor of impaired movement of the diaphragm plays a considerable part, and whether it be a phrenic reflex or a mechanical difficulty owing to the boarding of the abdominal muscles and the plastic adhesions so frequently present about the lower border of the liver, or both, is of little moment. It is of interest, however, in this connexion to note that over 50 per cent. of those patients showing pulmonary signs complained of acute shoulder pain, usually attributed to a phrenic reflex.

(3) That the lung condition is a blood infection settling in a part of the lung the expansion of which is restricted by the factors mentioned in (2).

The work of Else and of Rosenow has shown how liable the gall bladder is to infection through the blood stream. It is therefore perfectly feasible that the blood-borne infection which settled in the gall bladder might secondarily light on a part of a lung crippled by deficient expansion.

Frequency of Pulmonary Signs.

Since my attention was attracted to the presence of basal congestion in biliary infections I have operated on 31 acute cases. In 8 of these there is no note of an examination of the bases; of the remaining 23 crepitations were noted at the right base in 12, in 11 the examination was negative. In two cases pleural friction was present in addition to the moist sounds.

Influence on Prognosis.

In no case did any pneumonic complication follow operation. In one case a pleurisy with effusion was found on the day following the removal of a gall bladder full of pus. The bases of the lungs had not been examined in this case prior to operation, otherwise some abnormal physical signs would doubtless have been discovered.

There was no death in the series of 31 cases. In 24 cases ether anaesthesia was used, in 7 chloroform.

Conclusions.

The conclusions to be drawn from the study of these cases are:

1. That in a patient complaining of pain at the right costal margin and round the right side of the chest the discovery of crepitations or even of pleural friction at the right base does not preclude, but may support, the diagnosis of an acute biliary infection.

2. That such pulmonary signs are secondary to the biliary infection, and, far from contraindicating operation, will be effectively treated by dealing surgically with the primary focus of disease.

CAESAREAN SECTION:

WITH SPECIAL REFERENCE TO PRESENT-DAY INDICATIONS FOR OPERATION.*

BY

CHARLES J. G. TAYLOR, M.A., M.D. (OXON.),
HONORARY SURGEON TO THE NUNCEATON AND DISTRICT GENERAL HOSPITAL.

The operation of Caesarean section must always be a matter of supreme interest to general practitioners, as upon them rests the responsibility for the care and safety of the majority of mothers and their infants at the time of parturition. Herman classified the indications broadly into absolute and relative. Under the heading of absolute he included those conditions only which cause such a narrowing of the birth canal that the child, even after embryotomy, cannot be made to pass through the pelvis. All other conditions fall within the category of relative indications. During the past few years the list of relative indications has been enormously amplified, and careful judgement is called for in making a decision in individual cases between this operation and alternative methods of treatment.

Absolute Indications.

1. Extreme forms of pelvic deformity. As a general rule a space measuring 2 by 4 inches represents the very minimum through which delivery can be effected successfully either by cephalotribe or craniotomy forceps. It is safe to say that Caesarean section is absolutely imperative if the conjugate is 2 inches or less. Probably it would be more accurate to place the figure at $2\frac{1}{2}$ inches or less.

2. Hard solid tumours, fixed in the pelvis and causing narrowing to the extent that delivery through the pelvis is quite impossible.

Relative Indications.

1. *Contracted Pelvis.*—This is the most common condition for which Caesarean section is called for. It is generally agreed that a true conjugate of between $3\frac{1}{2}$ and $3\frac{3}{4}$ inches is the lowest limit permitting delivery of a living child. There is some slight variation of opinion among the experts as to which figure should be taken. I think myself we should accept the $3\frac{1}{2}$ inches true conjugate. But it is not enough to measure the conjugate only—the size of the child must be taken into consideration, and especially the size of the head, and whether the head can be made to engage comfortably in the brim. With a large child it may be advisable to choose Caesarean section with a true conjugate even of $3\frac{3}{4}$ inches, while it may be possible to deliver naturally a small child through a con-

jugate of $3\frac{1}{2}$ inches or less. Every individual case must be considered on its merits. What are the alternatives in these cases to Caesarean section? (a) Craniotomy—a barbarous operation not without risk to the mother, which might be avoided entirely if only the public and many practitioners were educated up to the supreme importance of the careful examination of the pregnant woman, especially all primiparae and all who have experienced previous trouble in labour. (b) Pubiotomy. I believe the scope of this operation to be very strictly limited to cases of minor contraction at the pelvic outlet. (c) Induction of premature labour. This is really useful only in minor cases of pelvic contraction. Obviously it is inadvisable to induce labour long before full term, as in all probability the child will die. I think we should practise this method as a rule only on women whom we have attended at a previous confinement and delivered by forceps after a struggle. We know then that a slightly smaller head will pass through the pelvis naturally, and, when pregnancy occurs again, by carefully estimating the size of the head from time to time we should be able to judge the correct moment for inducing labour. After induction of labour, maternal mortality averages 1 per cent., infantile mortality 30 per cent.—some say even from 50 to 60 per cent.

All that I have said up to now presupposes that we have been given the opportunity to examine our cases before labour has begun, and that we have diagnosed correctly the degree of deformity with which we have to deal. Unfortunately, as things are constituted at present, we do not often enjoy such opportunity; far more often we are summoned to a case with no more than a curt note from the midwife that "the baby is lodged." On examination we may find the membranes ruptured, the lochia drained away, and the head still above the brim. What are we to do if, after measuring the conjugate, we find that it is useless to attempt forceps delivery?

I think, having examined the available statistics, that in a case which we have every reason to suppose is grossly infected the safest procedure is craniotomy, and this follows as a matter of course if the child is already dead. If we know that examinations have not been frequent, the general circumstances satisfactory, and the child still alive, we should favour Caesarean section. Professor Munro Kerr thinks that the risks of setting up peritonitis may be considerably diminished by delivering the infant through the uterine incision, but leaving the placenta and membranes to be expelled by the vagina, thus avoiding contamination of the abdominal wound with the torn and almost certainly infected edges of the membranes. Others, again, advocate immediate hysterectomy in obviously septic cases. Whatever treatment we may adopt may involve considerable risk to the mother, consequently in dealing with a case of this kind we must weigh all the pros and cons with great care, and, above all, decide on a definite line of treatment without delay.

2. *Tumours.*—The most common tumours likely to interfere with the birth of the child are fibromyomata and ovarian cysts; other forms of tumours, such as enchondromata, osteomata, etc., are rare. Obviously if a fibroid blocks the passage of the foetus the only thing to do is to deliver by Caesarean section, and at the same time deal with the fibroid by hysterectomy. It not infrequently happens that a fibroid which in the early months of pregnancy appears to be obstructing the birth canal subsequently becomes drawn up out of the pelvis and ceases to cause any obstruction. It may be possible in these circumstances to remove the fibroid by myomectomy and allow the pregnancy to continue uninterrupted to term. There does not appear to be any undue risk of a miscarriage; of course the mere presence of a fibroid may bring on a miscarriage in any case.

In ovarian cysts as a rule Caesarean section is not called for. The cyst can be removed even after labour has begun, and parturition allowed to terminate naturally.

Other growths—of bone, cartilage, and so on—are of such rare occurrence that we need not waste any time discussing them. But there remains one very important form of growth which I think deserving of special mention. I refer of course to carcinoma, and more particularly, as the most common form met with, carcinoma of the cervix. Caesarean section for carcinoma of the cervix is not very frequently necessary. Pregnancy is likely to cause such a rapid exacerbation of the disease that in all likelihood our attention will have been called to it long before full term is reached. In such circumstances if the growth is operable we must urge the imperative necessity of a radical operation without delay and without regard to the life of the infant. In the event of the disease not being discovered until the late weeks

* A paper read before the Nuncaton and Tamworth Division of the British Medical Association.

of pregnancy, or supposing that, after having the circumstances and the dangers fully explained to them, the woman and her husband elect to risk all in favour of a living child, then delivery must be accomplished by Caesarean section, as the effect of a natural labour on the growth would be disastrous.

3. *Placenta Praevia*.—The treatment of this condition by Caesarean section was first advocated by Lawson Tait in 1898. His suggestion was jeered at by his colleagues, but he was less than twenty years ahead of his time. It is safe to say now that the majority of gynaecologists, though not all, regard Caesarean section as the standard method of treatment in practically all cases of central and lateral placenta praevia. In marginal placenta praevia the older methods are usually quite efficacious. In the central and lateral cases operation should be performed as soon as the diagnosis is made; there is usually an initial haemorrhage, probably not very serious, and on examination the os is sufficiently dilated to admit of the placenta being felt. Now is the time to do Caesarean section before a further serious haemorrhage makes the life of the mother precarious and that of the child hopeless. Foetal mortality by the older methods is between 50 and 70 per cent., and maternal mortality about 10 per cent.

4. *Eclampsia*.—During the last ten years Caesarean section has been frequently performed for eclampsia, but I cannot find that any of the experts give more than a somewhat qualified and guarded approval of the practice. Herman, who had a very large experience of this complication, makes the bold statement that four-fifths of all cases get well, and states with refreshing frankness his view that no treatment whatever is necessary—an opinion which was also shared by Matthews Duncan. Herman only justifies what he calls "meddling" as being the best means of keeping the patient's friends quiet. But I think Herman's figures err somewhat on the optimistic side. A considerable majority of eclamptics are primiparae, and the first stage of labour is often very considerably prolonged. Not infrequently a marked improvement sets in after delivery. I think, therefore, that Caesarean section is certainly justifiable, if not absolutely indicated, when the onset of eclampsia is early in labour and we are convinced from the way things are going that the first and second stages are going to be slow. Bleeding and transfusion of saline to dilute the toxins can quite well be carried out while the operation is in progress. I should like to mention one practical hint here which applies equally whether an anaesthetic is being given to control fits or for the operation—that is, not to give eclamptic patients chloroform. The morbid appearances after death from eclampsia are very similar to those produced by chloroform poisoning; both are set up by a condition of acidosis, and it is reasonable to argue that chloroform definitely does harm. Therefore, ether should always be given; it is just as simple and quite as efficacious.

In a sense allied to eclampsia we have the chronic nephritis of pregnancy, or chronic nephritis aggravated by pregnancy. It has been customary to teach that, should the condition of a patient not show considerable improvement under treatment by rest and strict milk diet, or should alarming symptoms develop, such as headache, vomiting, eye symptoms, or a marked diminution in the quantity of urine passed, the correct procedure is to terminate pregnancy by induction of labour. It is not as a rule necessary to do this till the later weeks of pregnancy. Induction of labour is not always a very certain proceeding, especially as regards time, so that in many of these cases Caesarean section may well be the method of choice, especially when we bear in mind that the mother in such cases is spared the undoubtedly great strain of ordinary labour.

5. *Concealed Accidental Haemorrhage*.—Caesarean section is only called for in the most severe forms of this condition in which other methods have been tried and failed. In these cases the baby is nearly always dead, so no efforts are called for on its behalf. The bleeding can generally be checked by complete rest, morphine, rupture of membranes, a binder, and injections of pituitary extract. If the mother does not improve then the only thing to do is hysterectomy, as the uterine muscle will have been so stretched and disorganized that retraction will be quite impossible.

6. *After Vento-fixation*.—Occasionally labour will be obstructed after this operation by reason of the cervix being so far tilted backwards that the presenting part cannot dilate it. Caesarean section then becomes necessary. The moral is, do not perform ventro-fixation on a woman of child-bearing age.

7. *Prolapse of the Cord*.—Caesarean section has been performed for this complication, but infant mortality does not appear to be thereby diminished, so it is hardly to be recommended as a routine practice. I think the same remark applies to—

8. *Impacted Shoulder Presentations*.—If the case is too far advanced for version I should imagine decapitation to be the best procedure, but Caesarean section has been performed very occasionally. The mortality rate is 50 per cent. for both mother and child in the few cases which have been recorded.

9. *Abnormal Conditions of the Child*.—A very large child even with a normal pelvis may occasionally best be delivered by the abdominal route, especially if it is presenting by the breech. Post-maturity is now, I think, generally accepted as a possible complication of pregnancy, and may not be of such infrequent occurrence as at one time was believed. Possibly a recent case heard in the law courts may be called to mind where, after taking expert evidence, the Lord Chancellor pronounced a child to be legitimate when it was born 331 days after the last possible chance of conception from the efforts of the lawful father. The child in such a case may be so large as to render Caesarean section necessary.

On rare occasions the operation has been performed for brow presentation, impacted breech, and persistent occipito-posterior positions. I think these cases should be regarded as constituting somewhat exceptional indications, and should require some other circumstance to justify operation.

10. *Retraction and Contraction Rings*.—It has happened that the after-coming head in a breech, and even the presenting head, has been caught and prevented from advancing by Bandl's ring. This might conceivably call for abdominal section.

11. *Scar Tissue and Rigid Cervix*.—Dilatation of the cervix may be unduly delayed by the toughness of scar tissue resulting from an operation or loss of elasticity of the normal tissue, the latter particularly in the case of elderly primiparae. Labour in some of these women is a terribly long business; if left to themselves the baby will probably die, and if forcible measures are adopted there may be very extensive laceration of the cervix and severe tearing of the perineum. I should imagine that a breech presentation in a primipara well advanced in her thirties or over forty causes more trouble and anxiety than any other problem of midwifery.

An unreduced occipito-posterior presentation may be almost as bad. Now, would it not be better to deliver many of these women by Caesarean section? The risk to the mother is very slight if operation is decided upon early, while the advantages may be enormous—a live and undamaged child, and results to the mother, both immediate and remote, very much more satisfactory. I do not, of course, advocate such heroic measures in every case of breech in a primipara—it is a difficult matter at the best of times to estimate the duration of a first labour—but I do think it would be worth while when we realize that a case is going to be protracted and we anticipate the kind of trouble I have described.

The operation has also been performed for extreme oedema of the vulva and very severe varix of the vagina and vulva. Obviously such cases must be treated purely on their individual merits.

12. *Serious Disease of the Mother*.—In such cases, particularly in fully developed mitral stenosis or advanced pulmonary tuberculosis, when the additional strain of labour may seriously imperil life, I have no doubt that the correct procedure is to perform Caesarean section. The shock of operation is far less than that arising from an ordinary labour of even moderate duration. From what I have seen in my own experience in other fields of surgery I would strongly advocate the use of a local infiltration anaesthesia in such cases.

Of *post-mortem* Caesarean section I need say no more than that it is possible to deliver a living child from twenty to twenty-five minutes after the death of the mother.

This completes the catalogue of indications, but there are still a few points to which reference should be made as having a distinct bearing on the subject of this paper.

First, as to the time of performing Caesarean section. Should we wait until labour has begun? On theoretical grounds it might be supposed that haemorrhage would be much less and more easily controlled during labour, but in practice it makes little or no difference. The manipulations of the uterus set up muscular contractions, and there need be no more haemorrhage in a case operated on before true labour has begun than after its onset. Again, should the patient be

sterilized at the time Caesarean section is performed, or should she be allowed to run the risk of becoming pregnant again? So recently as ten years ago it was widely held that the majority of cases should be sterilized at the time of the first Caesarean section. At the present day the general view is in complete opposition to this, and it is held to be rarely justifiable to sterilize a patient except in such circumstances as we have already considered, where the condition found at operation renders this course necessary in order to obtain a successful result—for example, hysterectomy for fibroids. Now that Caesarean section is so frequently performed for conditions other than obstruction in the pelvis, obviously there is no reason why many of the mothers should not have any number of subsequent labours—and a number do so. In cases of pelvic contraction, however, the view generally held is, "once a Caesarean always a Caesarean," and there are many cases on record of women undergoing Caesarean section four, five, or even more times, quite successfully. Unfortunately it is a fact that in a certain number of cases the uterine scar is not strong enough to withstand the strain of a subsequent pregnancy, and rupture of the uterus has been found to occur far too frequently. The direct cause of the weakness of the scar is sepsis at the time of the original operation.

Another fact to be noted is the relatively high rate of sterility following the operation. This, I think, is due not so much to the operation itself as to the fear that it engenders in the minds of the patients and their husbands and consequent avoidance of pregnancy.

In conclusion, I should like to emphasize, first, the supreme importance of educating ourselves and—a far more difficult matter—our patients and their mothers and mothers-in-law in the absolute necessity of keeping a careful watch on all women throughout the pregnancy. This is the only means of avoiding occasional emergencies. The urgent need for the provision of large towns and country districts. Possibly since the introduction of the panel system and the almost universal employment of midwives in maternity cases in industrial districts we may be able to view these questions in a more detached spirit than heretofore. In any case the remedy lies first and foremost in our own hands; if we make it our business to insist that beds for maternity cases are provided, I feel convinced that the time will not be far distant when women will clamour to be admitted to them.

CAESAREAN SECTION.*

BY

SAMUEL J. CAMERON, M.B., F.R.F.P. AND S.GLAS.,

ASSISTANT TO THE REGIUS PROFESSOR OF MIDWIFERY, GLASGOW UNIVERSITY; OBSTETRIC SURGEON AND GYNAECOLOGIST, GLASGOW MATERNITY AND WOMEN'S HOSPITAL.

CAESAREAN SECTION is one of the most spectacular but also one of the easiest of abdominal operations to perform if the patient has not undergone the operation on a previous occasion. With practice this operation can be accomplished rapidly; with an efficient staff of nurses and assistants I have performed the entire operation in seven minutes. A general practitioner with an average surgical training may safely perform it in cases of obstruction due to contracted pelvis, provided the case comes under observation early in labour and that he can secure thorough sterilization of instruments, suture materials, and gauze. On reviewing my more recent results I find that I have lost one patient in seventy-nine consecutive cases of Caesarean section. The only case which died succumbed to an ordinary bronchopneumonia ten days after operation. Ether alone had been administered in this case, and I would strongly urge that for purposes of anaesthesia chloroform should be used in preference to ether in the case of rachitic patients, as they are extremely susceptible to certain pulmonary disorders; a large number of them suffer from bronchitis and emphysema.

Within recent years the indications for the operation have been extended, and at the present time the obstetrician will be most liable to be called on to employ it in one of the following conditions:

1. In all cases of contracted pelvis where the obstruction prevents effectively the foetal head from engaging at the brim. In studying the causes of operative failure in my earlier cases of contracted pelvis I found that the chief danger was sepsis. At that time I performed the operation, even if forceps had been employed unsuccessfully by the practitioner, or if the membranes had been ruptured for many hours. As a rule the patients recovered, but a few died, and others had a prolonged convalescence due to septic infection. Accordingly I determined to operate only in cases which were probably free from contamination, and therefore I performed craniotomy in most cases which had been examined vaginally before admission to hospital, and in all of these cases if the membranes had been ruptured for longer than twelve hours.

2. Neoplasms in the uterus, ovaries, or pelvic bones sometimes cause such a degree of obstruction that Caesarean section has to be performed. As a general rule, cystic tumours of the ovary can be removed through the abdominal wound without incising the uterine wall, and whenever this is feasible it should be the operation of choice. In order to minimize the strain to which the abdominal wound is subjected during labour forceps should be employed when the second stage is reached. On the other hand, we can seldom remove a fibromyomatous tumour which has obstructed labour without first performing Caesarean section; nevertheless it is possible when a subperitoneal tumour is pedunculated, and in one instance of this kind I was able with my hand in the vagina to push the tumour upwards over the foetal head, and by so doing operative interference was avoided at the time. When a patient with a fibromyoma does not wish to be sterilized, occasionally we are able to perform myomectomy immediately after delivery has been effected by Caesarean section. As regards carcinoma of the cervix, the radical operation should be practised as soon as the case comes under observation if there be a reasonable chance of success; the child's life is of secondary importance. If the disease be too advanced to permit of extirpation, pregnancy should be allowed to proceed, and at full time Caesarean section should be followed by supravaginal hysterectomy, as the risk of sepsis is thereby diminished.

3. Excessive cicatricial contraction of the cervix and vagina may so obstruct labour that the lives of mother and child can be best safeguarded by Caesarean section. As a rule this difficulty follows an operation where the cervix has been amputated and the vaginal walls have been extensively denuded and sutured for the cure of uterine prolapse.

4. The operation is valuable in certain cases of accidental haemorrhage and placenta praevia, but in placenta praevia I recommend it mainly in cases where the patient is elderly and the child is alive. It seems to me that the operation should not be recommended in such cases if the patient be young, as she may be left with a weak uterine scar which may give way during a subsequent pregnancy. It is also a justifiable procedure in any case where the placenta is central and the os is not dilated. Many lives have been saved in cases of severe accidental haemorrhage by means of this operation. If the cervix be closed and the bleeding profuse it appears to be the most certain method of controlling the haemorrhage. Theoretically the proper procedure would be to remove the uterus without incising it, as the patient can ill afford any additional loss of blood, and by adopting this plan the main vessels supplying the organ are at once clamped. In practice I find, however, that evacuation of the contents shortens the operation, as the surgeon is not hampered by a bulky organ, and, after all, the loss of blood is relatively small. In cases of accidental haemorrhage I usually perform hysterectomy immediately after removal of the foetus and placenta, but this procedure is not always necessary, and cases may make an uninterrupted recovery after the uterine wound has been sutured in the usual way.

5. There is a tendency at present to advocate Caesarean section in cases of eclampsia, but as far as my observations go much better results can be obtained by less drastic measures which leave the uterus intact. I refer to induction of labour in combination with medicinal and other measures.

6. Vento-fixation and vaginal fixation of the uterus may disturb the position of the organ to such an extent that delivery by the natural passage is impossible, and in such circumstances Caesarean section is indicated. I have had personal experience of three cases of this character.

7. In rare instances this operation is performed in cases where labour is obstructed by a retraction ring which has formed in advance of the presenting part.

* Abstract of a lecture delivered to the Medico-Chirurgical Society, Queen Margaret's College, Glasgow.

Time of Operation.

The best time for operating on the patient is during the first stage of labour before the membranes have ruptured, as cervical dilatation ensures free drainage. In most instances, to suit my own convenience, I operate before labour begins. The patient is prepared in the usual way for an abdominal operation, and if a vaginal examination has been made recently a few antiseptic douches should be administered.

Site of the Abdominal and Uterine Wounds.

For many years I have operated on my gynaecological cases either through an incision in the rectus sheath or through a transverse wound. More recently I have adopted the incision through the rectus sheath in cases of Caesarean section, owing to the fact that a weak wound is liable to be obtained by a middle-line incision, as the abdominal wall in this situation is attenuated by the large gravid uterus. It is a matter of importance as to whether the right or left side is chosen. In my opinion the incision ought always to be made on the right side, as the uterus usually lies towards the right, and therefore the left margin of the organ approaches the middle line of the abdomen. Over a year ago I was performing the operation in the country, where the lighting equipment was miserable, and the uterus was exposed through an incision in the left rectus sheath. As soon as the uterine incision was made profuse haemorrhage occurred from the lower angle of the wound, and it was found that some large veins in the left broad ligament had been severed; great difficulty was experienced in arresting the haemorrhage. The left border of the uterus in this case was situated near the middle line, and if the incision had been made on the right side of the abdomen the above unpleasant complication would have been avoided. Two knives are always used by me—one for the abdominal and the other for the uterine wall—and I regard this as an important detail in my technique as it prevents infection of the uterine tissues if the skin be not sterile.

Every surgeon who has had a large experience in dealing with cases of repeated Caesarean section has probably on many occasions been hampered by numerous and dense adhesions in the region of the former scar or scars. The attachment of the uterus to the abdominal wall can often be diagnosed before the abdomen is opened, owing to movements communicated to the uterus being accompanied by dragging on the abdominal wall. If attached in the usual way the operation in these circumstances may be dangerously prolonged, and I have known a patient in the practice of an accomplished obstetric surgeon succumb from shock following a tedious operation of this description. In dealing with these cases I strongly advocate the evacuation of the uterine contents through transverse incisions in the abdominal and uterine walls. By so doing the surgeon can avoid the labyrinth of adhesions, and as the uterus is usually firmly fixed to the parietal peritoneum the organ will remain there in a state of ventro-suspension. Sometimes this attachment of the uterus to the parietes favours incomplete retraction, and on several occasions I have observed fairly profuse *post-partum* haemorrhage in such cases. As a rule I make the transverse incision a short distance above the upper extremity of the old scar; this will usually be above the level of the umbilicus and near the fundus of the uterus. On opening the abdomen the free portion of uterine wall near the fundus is severed transversely, and the child is extracted.

Treatment of the Uterus.

Before opening the uterus I insert four large swabs, so that two are situated laterally and the other two at the upper and lower angles of the abdominal wound. The swabs are not removed until the wound in the uterine wall has been closed. After the uterus has been opened the operator should feel for a leg and drag the limb through the wound. If he discovers that he has seized a hand he should at once release it and find a leg, as the child should be delivered as a breech. As the limb is often greasy, the nurse who is attending to the dressings should keep a swab in readiness to pass to the operator to prevent his hand from slipping during the extraction. Immediately the child is delivered the uterus should be drawn through the abdominal wound on to the abdominal wall. There the organ should be turned inside out, so that the placenta and membranes can be stripped from their attachment. For this purpose a large pledget of gauze will be found most useful. In most instances the membranes in the region of the cervix are the most difficult to detach, and it is highly desirable that they should be entirely removed, as

even a small portion overlying the os may prevent the lochia from escaping for several days.

When the extraction of the placenta and membranes has been accomplished the inner wall is thrust back into position in order that the uterine wound may be closed. The method which I now adopt is to begin by inserting three interrupted sutures of silk; one suture is placed in the middle of the wound and the other two midway between the first suture and the upper and lower angles of the wound. Each suture passes through the entire depth of the uterine wall, with the exception of the inner layer. These sutures are firmly secured, and the remainder of the wound is closed with similar sutures of catgut. Finally a continuous suture of catgut is used throughout the entire length of the wound. The three sutures of silk are a safeguard in case the catgut becomes absorbed too rapidly.

Closure of the Abdominal Wound and After-treatment.

As soon as the wound in the uterus is closed the four large swabs are withdrawn and the abdominal incision is closed in layers. For many years I have used anchor sutures to support the wound and to keep the small gauze dressing in position. No other covering is applied to the wound. Before the patient leaves the operating table the surgeon should observe whether blood is escaping from the vagina or not; if it is not, he should grasp the uterus and compress it through the abdominal wall. Dilatation of the cervix may sometimes be necessary to remove an obstructing portion of membrane.

In my surgical practice I have for many years allowed my patients every liberty of movement as soon as they become conscious after the operation. They are encouraged to lie on their side and to sit upright in bed in Fowler's position. By so doing drainage is promoted, flatulence is diminished, convalescence is shortened, and the liability to thrombosis is lessened.

ECLAMPSIA: EVOLUTION AS A CAUSATIVE FACTOR.

BY S. E. KARK, M.B., CH.B. EDIN.,
CAPE TOWN.

BEFORE proceeding in detail with the subject-matter of this paper I must briefly summarize a paper dealing with the general causation of the toxæmias of pregnancy read by me at the recent South African Medical Congress held at Cape Town (October, 1921).

1. A normal pregnancy is one in which all the changes that take place incidental to that condition are necessary for the purpose of gestation—that is, all the changes brought about must be functional.

2. As with almost all pregnancies there are concomitant functionless changes apart from frequent pathological-like manifestations, it is evident that almost all pregnancies are not quite normal.

3. To explain this anomaly in nature—that such an important physiological process as gestation should almost always be abnormal—I advanced the view that in the process of evolution of the various vital functions of the body the placental form of reproduction was evolved last and comparatively late. While all the other vital functions are now mature and harmoniously correlated to each other, gestation is still in some degree developmentally immature, hence its many physiological imperfections. In consequence of this tardiness in the process of evolution of the placental form of reproduction, the pregnant state approaches in some degree primitive conditions; gestation is, as it were, a physiologic atavism. This is evidenced by the following facts:

A. That in the pregnant woman the secondary feminine characteristics often become less marked; she approaches the masculine type in many respects—that is a recession towards the primitive state, in which secondary sex characteristics were not as yet markedly differentiated. This metamorphosis towards masculinity is shown by the frequent occurrence in pregnancy of:

- (a) Overgrowth of hair on the body, especially on the face.
- (b) Coarsening of the features.
- (c) Thickening of the skin.
- (d) Hypertrophy of some of the bones.
- (e) Enlargement of the hands and feet.
- (f) The stability of calcium metabolism.

B. Another result of this physiologic atavism of pregnancy, and one fraught with even more important and far-reaching

consequences is the "survival" of the state of hyperpituitarism in pregnancy. In this respect also the pregnant woman approaches the condition of primitive man—the Neanderthal giant—who has been shown to have been in a condition of marked hyperpituitarism.

Hyperpituitarism in Pregnancy.

The pituitary body has been shown to increase greatly in size and in weight during pregnancy. Not only does the anterior lobe increase in bulk, but remarkable histological changes take place in the kind and number of cells. New kinds of cells—the neutrophil cells, the "pregnancy cells" (called by Bell the "emergency secretory cells" of the pituitary body)—now make their appearance in enormous numbers, and, from the way they assume a lobulated or an adenomatous arrangement, suggest a glandular hypertrophy.

This marked glandular hypertrophy must mean also augmentation of the secretory function. We may therefore reasonably assume that the increase in the amount of the "hormone of growth," as Cushing calls the pituitary, is responsible for stimulating the growth and development of the foetus (probably by altering the metabolism of the woman from the usual calcium instability to one of calcium retention); for the expulsion of the foetus (by its infundibulin) when mature; and, by its galactagogue action, provides for the sustenance of the foetus after expulsion. At the same time it produces in the woman certain changes: some functional, such as the growth of the uterus, the increase of the pelvic girdle; some functionless; and some morbid, the relation of which to hyperpituitarism can best be studied clinically.

The analogy between acromegaly—a condition admittedly due to hyperpituitarism—and certain abnormal cases of pregnancy has been pointed out by many authorities.

I have shown (in the paper on toxæmias of pregnancy mentioned above) how practically all the manifold changes—functional, functionless, and morbid—that take place in the pregnant woman are very much like those produced by hyperpituitarism. Here I will endeavour to show the relationship of this hyperpituitarism in pregnancy to eclampsia.

Hyperpituitarism and Eclampsia.

In studying the sequence of the various cardinal symptoms of eclampsia, as well as of the other toxæmias of pregnancy, the following important facts seem to stand out quite clearly—namely, that as the physiological requirements for the process of gestation from the commencement to the end of pregnancy are stimulated by the hormone from the anterior lobe, the pathological changes likewise manifested from the beginning to the end of pregnancy are due to overactivity of that part of the gland. Again, as the physiological requirements for the latter stage of pregnancy are supplied by a stimulus from the posterior lobe—for example, infundibulin for the expulsion of the foetus—the pathological conditions peculiar to the latter stages of pregnancy are similarly the resultants of the overactivity of the posterior lobe, superadded on those morbid changes which are due to the hyperactivity of the anterior lobe.

These facts not only explain why eclampsia is almost always a disease of advanced and the end-period of pregnancy, but they also furnish us with an etiological and physiological basis for the usual clinical divisions of the symptoms of eclampsia into prodromal, pre-eclamptic, and eclamptic; for, as will be seen, the prodromal symptoms are due solely to the overactivity of the anterior lobe, the pre-eclamptic symptoms are the result of the overactivity of both the anterior and posterior lobes, while the eclamptic symptoms are due to oversecretion of the posterior lobe only.

A. Symptoms Due to Anterior Lobe.

Prodromal.—The prodromal symptoms are due to overactivity of the anterior lobe, and are mainly subjective symptoms of the same nature as those met with in early pregnancy and also in early acromegaly; these are:

In Eclampsia:

- (1) Nervous irritability and excitability and a certain degree of nervous unbalancing.
- (2) Vomiting and epigastric pain.
- (3) Headaches.
- (4) Tendency to drowsiness and sleep.
- (5) Cramps and twitchings of muscles.

In Acromegaly:

- (1) Similar symptoms to those recorded under eclampsia (1) are met with in early acromegaly.
- (2) As in eclampsia, vomiting and epigastric pain are also symptoms in some cases of acromegaly.
- (3) Cushing thinks the "pituitary headaches" are due to distension of the glandular envelope. Blair Bell ascribes them to increased secretion, and cites cases where the internal administration of the anterior lobe extract often caused severe headaches.
- (4) Somnolence is a symptom in early acromegaly.
- (5) Cramps and twitchings of muscles (as in eclampsia).

Pre-eclamptic.—The pre-eclamptic symptoms are due to hypertrophy of both parts of the gland. Those due to the anterior lobe are objective symptoms, which are caused by the hypertrophy and increase in the size of the anterior lobe producing pressure symptoms on neighbouring centres and nerves; thus we have as a result of pressure on the optic tracts or of the chiasma symptoms of disturbed vision, such as flashes of light, coloured lights, commonly called spangles, photophobia, hemianopsia, amblyopia, amaurosis, and even complete temporary blindness, while pressure on the third nerve is responsible for diplopia and even external strabismus.

B. Symptoms Due to Posterior Lobe.

The pre-eclamptic symptoms caused by overactivity of the posterior lobe are due to its well-known pressor action on the blood vessels and the consequent rise of blood pressure. This furnishes us with the most important and an early danger signal of an impending attack; hence we must constantly watch for a pulse with a high tension and an accentuated second heart sound.

As regards changes in the urine, this is not such a constant feature of eclampsia as raised blood pressure; but generally the urine is diminished, has high specific gravity, contains albumin, blood, and hyaline, epithelial, and granular casts. My explanation for these morbid changes in the kidney is that, as Herring and Schafer have shown that the extract of the posterior lobe has a distinct stimulating effect on the renal secretory cells, one may assume that a prolonged overstimulation with a sudden absorption of a great quantity of the stimulus would produce the opposite effect of depression of the secretory cells of the kidney (there may possibly be also a condition of dyspituitarism). In this connexion Thoa's record of haematuria produced as a late result in animals injected repeatedly with infundibulin is very suggestive.

Eclamptic.—The violent tonic and clonic convulsions in eclampsia are entirely due to an overstimulation of the posterior lobe producing, by its well-known pressor action, contractions and spasms of the blood vessels of the brain, thus causing anaemia and oedema of that organ. Dührssen suggested this spasm of the blood vessels of the brain, kidney, and liver as an explanation for the convulsions in eclampsia. The causative factor producing this spasm of the vessels he thought was an "irritation proceeding from the uterus," but the specific pressor action of the posterior lobe on the arteries being well known the primary cause for this spasm is quite evident. In this connexion one may mention Bell's experiments; he produced twitching of the muscles in animals subjected to repeated injections of infundibulin. Another interesting point to note is that in eclampsia the pupils are widely dilated, as opposed to the contracted pupils in epilepsy. Now Cramer has shown that infundibulin produces dilatation of the pupils in the enucleated eye of the frog.

PATHOLOGICAL ANATOMY.

As the most prominent and fatal symptoms of eclampsia are, according to the view propounded in this paper, due to an excessive secretion of the posterior lobe, we would expect the post-mortem findings in eclampsia to show such morbid changes in the various organs as may fairly be ascribed to that cause; especially should we find evidence of irritation in the posterior lobe. That this is the case is evident from the following:

Morbid Changes in the Pituitary.

1. Blair Bell finds in the pars anterior a predominance of basophil cells, colloidal substance in the pars intermedia and in the cleft, and an extensive invasion of the pars nervosa by the cells of the pars intermedia. The same author remarks on his findings: "This invasion of the pars nervosa may lead to an excessive production of infundibulin."
2. Clifford White, who examined carefully *post mortem* all the ductless glands of a patient who died two days after

labour from no evident cause (a case probably of eclampsia without convulsions), finds similar conditions in the pituitary as Bell. In the pars anterior he also finds "large cells whose protoplasm stains feebly with any stain—exhausted secretory cells (?). The pars nervosa has been invaded by the large eosinophil cells from the anterior lobe."

Brain.—*Post-mortem* findings in the brain in eclampsia are "moderate oedema of the convolutions, sometimes with anaemia, sometimes with congestion." These changes may reasonably be brought about, as explained before, by sudden spasm and contractions of the blood vessels of the brain.

Liver.—"The most typical changes *post mortem* are albuminoid degeneration, with . . . anaemic necrosis. These focal necroses occur . . . portal vessels." These changes are produced by spasm of vessels as explained above. Hepatic degeneration with marked necrosis of liver cells has been produced in animals experimentally by Carro by continuous injections of infundibulin. This spasmodic necrosis is probably the causative factor also of the condition of acute yellow atrophy of the liver in pregnancy.

Kidney.—"The most common changes in the kidney in a majority of cases are those of an acute nephritis, and this is hard to distinguish from an acute parenchymatous nephritis." The cause of these changes in the cells of the kidney I explained above.

I think I have adduced sufficient evidence to show that eclampsia—in common with all the other so-called toxæmias of pregnancy—is brought about not by some accidental external agent, nor is it the result of some morbid derangement producing poisons or toxins from either the foetus, uterus, or intestine, as most of the theories advanced on the toxæmias of pregnancy assume; but that it is essentially a physiological process *overdone*—due to an excess, rather than a perversion, of an essential product.

Why nature should, in the process of gestation, so often overshoot her mark, and thus defeat her own aim, is due to the comparatively short evolutionary experience she has had of this, her newest experiment in reproduction—the placental form.

CONTINUOUS TREATMENT IN SURGICAL TUBERCULOSIS.*

BY

F. W. GOYDER, M.B., F.R.C.S.,

HONORARY SURGEON, BRADFORD ROYAL INFIRMARY, AND ORTHOPAEDIC
SURGEON TO EDUCATION AND HEALTH COMMITTEES, BRADFORD
CORPORATION.

In recent years so much work has been done with regard to the treatment of tuberculosis of the bones and joints, and in both medical and lay papers so much has been written, that further insistence on principles now firmly established and fully recognized may seem unnecessary. The work of Sir Robert Jones, of Sir Henry Gauvain at Alton, and of Calvé, Calot, and others at Bercy-sur-Mer and elsewhere, and the discussion at the Annual Meeting of the British Medical Association in 1921, have shown clearly what can be effected by organized and continuous treatment in this direction. But it is doubtful whether in this part of the country we have followed in the footsteps of our leaders as closely as we might. Perhaps on close examination it may be found that although we have acknowledged our belief in continuity of treatment in surgical tuberculosis, this belief has never been translated into action, and, as we are told, "Faith without works is dead." Those of us who are surgically minded are still too apt to regard an operation as the whole treatment in this disease, instead of a mere incident, and an incident which continuous treatment has made less frequent and of diminishing importance. Others, who, having been impressed by

certain unsatisfactory results following operation, have decided to do without it, have made no serious or continued attempt to establish the conditions necessary to avoid operation. These mistakes appear to have arisen because we do not continually bear in mind that surgical tuberculosis is a disease whose duration is measured in years and not in months, and that during the whole of the active period and for some time after we cannot afford to relax our vigilance for a moment. If we do, we run the risk of lengthening the necessarily long duration of the disease, and of permitting the existence and increasing the severity of deformity. Relaxation of continuous supervision in the early stages leads often to rapid spread of the disease, to abscesses which might have been prevented, to deformity difficult or impossible to correct when the condition becomes obsolete, and to the necessity for serious and often mutilating operations. Those who advocate early operation in these cases insist on careful and continued after-treatment. How much more, then, is it necessary if the condition is too advanced for complete eradication of the tuberculous lesion? When such an operation is apparently successful, how unpleasantly often does the return of disease, or at the very least deformity, show that after-treatment has been too brief! How seldom, in spite of all that has been written, does recovery take place without leaving the patient a cripple!

The necessarily long course of the disease makes continuous in-patient treatment in general hospitals almost impossible, and leads almost inevitably to periods of neglect, or loss of interest in, treatment. During such intermissions the disease breaks out afresh into activity or deformity increases. Once it is recognized that deformity can be prevented, and when present can be minimized only while disease is active, the present disconnected methods will have to give way to a continuous supervision.

In Bradford there are no fewer than six institutions which deal with surgical tuberculosis. Of these, three act entirely independently of the rest. They are hospitals whose constitution precludes long periods of in-patient treatment. The other three are, in theory, linked, but since no one of them was primarily established to deal with surgical tuberculosis, they suffer from the defects of overlapping and lack of co-ordinated surgical supervision. They are a sanatorium to which, along with phthisis, cases of active surgical tuberculosis can be sent; a cripple school where, amongst other conditions, surgical tuberculosis believed to be obsolete can have the benefits of such treatment as is possible for a finally fixed deformity; and a special hospital where, with other orthopaedic cases from this school, the large percentage of cases of supposed obsolete tubercle which prove to be active can have emergency treatment. The last two institutions contain the germ of an ideal scheme and afford at the present time the only attempt to solve the problem of continuous treatment of surgical tuberculosis in the city.

To get the best results it should be possible for all children suffering from this condition to obtain systematic treatment during the whole period of active disease and for some time afterwards. If we include the infants' and children's clinics and exclude the special hospital fed from the Cripple School we have seven separate "nets" the gaps between which are filled by the medical practitioners of the city. The active cases thus "caught" in many instances escape from the net before they are "cured" (if I may venture to continue the metaphor) and are picked up again if seriously crippled at the medical inspection of school children. They may thence be sent to the Cripple School, but too late to prevent or cure deformity. Hence the weak point in Bradford is the provision for active or acute cases.

The Cripple School has accommodation for about two hundred children, of whom some 40 per cent. are or have been cases of surgical tuberculosis. The cases of active disease can and do have the benefit of recumbent, postural, and other forms of active . . . plaster, and ultimately of properly made . . . jackets and other appliances. By a wise provision such cases are resident from Monday to Friday in each week, and for the week-end or during periods when active surgical interference is required are transferred by ambulance to the special hospital linked to the school. In suitable cases they spend their week-ends at home. Under these favourable conditions I have been able to keep cases of spinal caries recumbent for two years and to watch them through the critical period of their gradual return to active life. And all this has been possible without interruption of their education. An extension of this scheme to include admittedly active cases is all that is needed to put

*A paper read before the Bradford Medico-Chirurgical Society on January 10th, 1922.

the treatment of surgical tuberculosis in Bradford on a proper footing. The school is healthily situated, sanatorium conditions exist, and facilities for nursing and massage are adequate. It is not too far from the town to justify a possible complaint of the parents that they are losing sight of, or touch with, their children.

In an industrial town such as Bradford, where the cases are sufficiently numerous, the most effective way of dealing with the problem is also likely to be the cheapest. It is primarily a hospital problem applied to children of school age; but since such cases under proper supervision are not ill, school teaching with suitable manual training can, and should, be given at the same time. There is no reason why in-patient (recumbent) and out-patient (ambulatory) cases should not be taught at the same institution, and this would have the further advantage that medical supervision by the same people would be practicable for both classes of case, and the after-treatment of the cured would be in the hands of those responsible for the cure. Much overlapping would be prevented, much better results would be obtained, much needless deformity would be saved, education and treatment would continue without gaps, and a larger percentage of useful citizens would be the ultimate outcome. An after-care association for those beyond school age would round off and complete the scheme.

THE NITROGEN METHOD AS AN AID TO DIFFERENTIAL DIAGNOSIS IN MENTAL DISEASE.

BY

R. V. STANFORD, M.Sc., Ph.D.,

RESEARCH CHEMIST, CARDIFF CITY MENTAL HOSPITAL.

In certain types of mental disease, and notably in general paralysis of the insane, clear evidence is to be found *post mortem* of degeneration of the brain tissues, whilst in other forms of mental disorder exhaustive macroscopic and microscopic examination has failed to reveal anything abnormal.

Since a correct diagnosis is essential to correct treatment and to prognosis, and since general paralysis is incurable in the present state of our knowledge, it is obviously a matter of considerable importance to establish any diagnosis of that disease with as much certainty as possible, and as early as possible, more especially because there are other forms of mental disorder which may simulate it very closely in the earlier stages.

Apart from my nitrogen method, which is the subject of this paper, there are essentially two laboratory methods which have been extensively employed to elicit or to negative the diagnosis arrived at by clinical observations. These are the Wassermann reaction (in the blood and in the cerebro-spinal fluid) and the reactions for excess of protein in the cerebro-spinal fluid. In both these ways valuable information may sometimes be obtained, but their limitations are considerable. A very thorough discussion of the subject will be found in Goodall's Croonian lectures.¹ Here it need only be mentioned that the applicability of the Wassermann reaction as a diagnostic test for general paralysis rests on the basis that general paralysis is a syphilitic manifestation. It will be seen, however, from the discussion of the matter above cited that different observers have found widely differing percentages of positive results in undoubted cases of general paralysis—a fact due, no doubt, to the inherent uncertainty of the reaction, for it is well known that experienced observers frequently fail to obtain similar results from the same sample. Generally speaking, it appears that positive results, whether in the cerebro-spinal fluid or in the serum, are obtainable only in something like 60 or 70 per cent. of undoubted cases of general paralysis. This compares unfavourably with the 90 per cent. of positive results in cases of syphilis, and it should also be pointed out that positive results were found in 7 per cent. of the cases other than general paralysis.

The reactions for protein in the cerebro-spinal fluid are numerous, but all aim at revealing the presence of an excess of protein in the fluid, the presence of such protein being indicative of abnormal degeneration of the brain tissue. The rapid and simple Nonne-Apelt reaction, in which any proteins are salted out by the addition of an excess of ammonium sulphate, has been the most used and is probably the most reliable procedure. Unfortunately, this test frequently fails

to give a positive result in cases where the products of degeneration are not present in the form of coagulable proteins. In fact, it would hardly be too much to say that the Nonne-Apelt reaction cannot be relied upon excepting in cases where degeneration is so definite and well marked as to make any laboratory assistance superfluous to a physician of experience.

These references to the Wassermann and protein reactions are designed to show that the diagnosis of general paralysis is by no means so simple and straightforward as it is sometimes represented to be, and that there is every justification for the laboratory to provide additional methods such as that referred to in this paper to assist the clinician.²

Choline.

Many workers have endeavoured to detect in the cerebro-spinal fluid during life evidence of the breakdown of cerebral tissue, which undoubtedly occurs in general paralysis, brain softening, and some other conditions. Many years ago it was claimed by some that in such degenerative conditions choline (derived from the phosphatides of the brain) could be found in the cerebro-spinal fluid. Others, repeating this work, failed to confirm the results. In an investigation of this question I was fortunate enough to discover not only the truth of the matter, but also an explanation of these contradictions. There is no choline in cerebro-spinal fluid, and there is no ammonia. But when cerebro-spinal fluids, especially if they are derived from cases of general paralysis, or obtained *post mortem*, are treated in the (chemically speaking) barbarous way adopted by some of the investigators, decompositions occur, and there are produced (1) a substance which, although not choline, gives some of the alkaloid reactions shown by choline, and (2) ammonium salts which form a platinumchloride only distinguishable from choline platinumchloride by the polarization method first suggested and employed by Kauffmann.³ If a freshly obtained fluid is worked up with due precaution, neither the pseudo-alkaloid nor the ammonium platinumchloride is obtained.

THE NITROGEN METHOD.

It has been mentioned that the object of the choline researches was to obtain evidence during life of abnormal degenerative processes in the brain. The finding of choline or ammonia in the cerebro-spinal fluid would have been such evidence, but when the investigation just described had shown that these substances were not really there, it still seemed probable that evidence of the presence of products of degeneration might be obtained by other means. The origin, use, and fate of the cerebro-spinal fluid are still obscure, but as it is in intimate contact with the tissues of the central nervous system, it is natural to suppose that its composition might reflect any changes in the katabolism of those tissues.

In these circumstances I devised a method for the rapid and accurate estimation of the total nitrogen present per cubic centimetre of the cerebro-spinal fluid, and in 1913⁴ published an account of the method and of the results obtained by means of it in about seventy cases of mental disease. It is unnecessary to describe the method in detail, the more so as the paper is available in English.⁵ It need only be mentioned that 1 c.c.m. of cerebro-spinal fluid is heated with fuming sulphuric acid, the reaction mixture is diluted with water, made alkaline, and distilled into a series of Nessler cylinders, where the ammonia is estimated by Nesslerization, as in water analysis. The whole process, excepting perhaps the actual Nesslerization, can be carried out by any laboratory boy of reasonable intelligence. The process is also fool-proof. In view of the very small quantity of material, certain precautions have to be taken in regard to cleanliness, and in this matter a little supervision may be required, but the effects of any carelessness are at once apparent.

Differential Diagnosis by the Nitrogen Method.

Since 1913 the nitrogen method has been in routine use in this hospital as an aid in diagnosis. The claims made for it at that time have now been substantiated over a much larger number of cases, and it is the object of this communication to describe the results which have been arrived at. These results are set out graphically in the accompanying Diagrams 1 and 2, which include 254 cases.

A word is necessary in explanation of the graphic mode of representation employed in Diagram 1, which is due to my wife, Mrs. Helen L. Stanford, B.Sc. Lond. In the original paper it was shown that the nitrogen number (NN) being the

number of hundredths of a milligram of total nitrogen per cubic centimetre, lay usually below 20 in cases of mental disease other than those of general paralysis, and almost always above 25 in cases of general paralysis. Diagram 1, into which 254 cases are compressed, illustrates this at a glance. The nitrogen numbers are printed consecutively under the heading NN at the left of the page. Opposite any particular nitrogen number there is printed a circle for each case not general paralysis found to have that particular number, and a stroke for every case of general paralysis found to have that number. Thus, opposite 17 there are 5 circles, showing that five non-general paralysis cases were found to have this number. Opposite 19 are printed 22 circles and 4 strokes, showing that twenty-two non-general paralysis and four general paralysis were found to have that number. When we get above 25 it will be seen that practically only strokes are present. The neatness of the device as a method of graphic representation depends on the fact that the two sets, the circles and

Cases of insanity with gross brain lesion and of certain other types have been omitted from this table.

DIAGRAM 1.—Showing differential diagnosis of general paralysis from other mental disorders.

the strokes, can be printed over one another with ease, and consequently the ambiguous area of overlapping is patent to the eye. It will be seen that the ambiguous region stretches from about 20 to 26. Experimental errors will creep into the most fool-proof processes, and although I am bound to include them, I have grave doubts of the solitary case of general paralysis at 15 and of the odd non-general paralysis cases above 26.

In view of the number of cases included in this ambiguous area it might be supposed that the nitrogen method was in little better case than the Wassermann and Nonne-Apelt reactions in its reliability as an aid to diagnosis, but there are fortunately already two answers to such an objection. One is that by a method for the estimation of the total carbon of the fluid—an account of which I hope to publish shortly—it is in most cases possible to differentiate between general paralysis and other forms of mental disorder, even when their nitrogen numbers lie in the ambiguous zone between 20 and 26. The other point is that, according to many observations of mine, the composition of the cerebro-spinal fluid is remarkably constant where there is no progressive disease. If a patient has been found to have a nitrogen number of, say, 23, which is ambiguous, light will frequently be thrown on the case by examining another sample a few weeks later.

It is evident from the results shown in Diagram 1 that if the nitrogen number is below 20 there is a great probability against general paralysis, and that if it is above 26 there is an overwhelming probability in favour of that disease. There are, however, certain reservations to be made. The nitrogen method not only reveals but measures the products of excessive katabolism in the brain tissue, but it does not, of course, indicate the cause of that excessive breakdown of tissue. In Diagram 1 there are included only undoubted cases of general paralysis and cases of mental disorder undoubtedly not of general paralysis. The nitrogen method shows up also cases such as those of brain tumour, meningitis, and recent or remote cerebral haemorrhage, but such cases have been excluded from this diagram because they would not in any event be mistaken for general paralysis clinically.

Normal Cerebro-spinal Fluid.

It is a matter of great difficulty to obtain samples of normal cerebro-spinal fluid derived from living subjects. In Diagram 2, column 11, headed "Not Insane," will be found records of the total nitrogen in twelve such cases, and it will be seen that they range from 15 to 22.

DIAGRAM 2.—Showing the nitrogen numbers met with in common types of mental disease other than G.P.I.

This is of particular interest because, in spite of the extent of the literature on this subject, there do not appear to be any trustworthy data available as to the chemical composition of the fluid either in health or disease. There is good reason for this. Cerebro-spinal fluid contains only about 10 mg. of dissolved matter per cubic centimetre, and of this more than 8 mg. consists of inorganic salts, principally chlorides. Whoever wishes to investigate the organic constituents of the fluid has therefore something like 2 mg. of material per cubic centimetre to work with, or, assuming that 10 to 12 c.cm. is as much as it is desirable to withdraw excepting in certain forms of disease, he has 20 or 25 mg. of substance on which to exercise his analytical abilities. The consequence is that most of the results which are contained in the literature of the cerebro-spinal fluid have been obtained either by mixing numbers of fluids together, or from fluids obtained *post mortem*, for only in such ways could the problem be brought within the scope of the analytical chemical methods already known. It is obvious that no information of value can be expected from the examination of mixtures of fluids, and I shall now proceed to quote some results which go to show that the approach and occurrence of death are accompanied by such remarkable changes in the cerebro-spinal fluid as to render any observations that have been made on *post-mortem* fluids quite meaningless as regards the living subject.

Changes Associated with Death.

The starting point of these observations was the finding of an exceedingly high nitrogen number in a case which died.

shortly afterwards. Since then I have been able to investigate the fluid in about a dozen other cases either shortly before or shortly after death had occurred. In every case the approach or occurrence of death led to a large increase in the nitrogenous contents of the cerebro-spinal fluid. For example, Case No. 20 had been suffering from general paralysis for fourteen months and his nitrogen number had gradually increased from 25 to 39. He died eleven days after this, and his fluid, withdrawn by lumbar puncture thirty minutes after death, gave NN 109. In another case (No. 3), diagnosed as confusional insanity, the nitrogen number had been found to be 24 and 27 on two occasions during life. One hour after death it was 38, and twenty hours after death it was 88.

Results similar to these two instances quoted were obtained in every case examined, and they leave no room for doubt that a very remarkable change in the composition of the cerebro-spinal fluid begins to take place shortly before death and continues after it. Whether this is directly due to excessive katabolism in the brain tissue, or whether it is due to a partial breakdown of the cells secreting the cerebro-spinal fluid, is a matter of speculation, but it is a matter of fact that it does occur and that in consequence any analyses of fluids obtained *post mortem* are valueless, for they bear no relation to the composition of the fluid during life, which is the only thing that matters. It is unfortunate that this objection renders valueless a great deal of the work on cerebro-spinal fluid recorded in the literature.

The Nitrogen Number of Cases other than General Paralysis.

It is well known that although every effort has been made to discover a physical basis for mania, melancholia, and other commonly occurring forms of mental disorder, no such basis has ever been found. These forms of mental disorder have been investigated histologically, bacteriologically, chemically, and in many other directions, but in all cases with negative results. It remains to be seen whether the study of the cerebro-spinal fluid during life may solve the problem, but the results exhibited in Diagram 2 show that the nitrogen method by itself brings no help in the matter.

The scheme of graphic representation employed is the same as that in Diagram 1, a circle indicating a case of the disease found to have the nitrogen number opposite which it is placed. It will be seen that in all the ten types of mental disorder included in the table the circles are pretty uniformly distributed between about 15 and 22, and that this is also the range of the cases not insane in column 11. There is therefore no differentiation between the different clinical types recorded or even between them and the cases not insane.

Variations in Progressive Disease.

In a progressive disease such as general paralysis it might be expected that the nitrogen number would mirror to some extent the course of the disease: that when the patient was going downhill the nitrogen number would increase, and that a stationary state or a definite remission would be accompanied by a stationary or a reduced nitrogen number. I have records of fourteen cases of general paralysis in which samples of the fluid had been obtained from time to time, and in some of these the expected parallelism is to be noticed. As examples I may cite the following cases:

Case 20.—Aged 41. Admitted January 2nd, 1911. Had seizure in December, 1911. Died February 27th, 1914.

December 10th, 1912: Nitrogen number 25. Patient in stationary state; considerably demented.

January 22nd, 1913: NN 27. Condition unchanged.

April 9th, 1913: Condition unchanged; in partial remission, no seizures. NN 27.

On June 16th, 1913, the nitrogen number was 29, and on September 29th it was 25.

December 15th, 1913: Disease progressing rapidly; several seizures. Nitrogen number 30.

February 16th, 1914: Nitrogen number 39.

February 27th, 1914: Fluid taken thirty minutes after death. Nitrogen number 109.

Case 222.—Male, aged 45. Admitted about February, 1921. On March 9th, 1921, the nitrogen number was 40; disease in active phase. On March 30th, 1921, the disease was still in active phase. On April 1st, 1921, the nitrogen number on both dates was 35. On April 1st, 1921, he had a quiet interval.

From October 6th: Growing more excited daily. Nitrogen number 30. October 21st: Still excited. Nitrogen number 29.

In remission from about November 19th, 1921. The patient had received an intensive course of treatment with salvarsanized serum, and, his remission continuing, was released on trial in January, 1922.

In other cases, however, the figures for the nitrogen number do not fit the condition of the patient so well.

Insanity with Gross Brain Lesion.

It has already been pointed out that the nitrogen number reveals abnormal breakdown of tissue without indicating the cause of that breakdown. The following cases illustrate this:

Case 101.—Syphilitic meningitis. On November 10th, 1913, the nitrogen number was 57; on March 2nd, 1914, it was 31; and on March 30th, 1914, it was 27. The patient was discharged relieved on July 30th, 1914.

Case 137.—Semi-recent cerebral haemorrhage, verified *post mortem*. On June 8th, 1914, the nitrogen number was 32. Patient died eight days later (June 16th).

Case 201.—The patient died from brain tumour on September 26th, 1919. The nitrogen number on September 24th was 273.

Case 250.—The patient died from brain tumour on the day of puncture (December 1st, 1921). Nitrogen number 44.

Senile Dementia and Senility.

Reference to Diagram 2, column 9, will show that in cases of secondary or terminal dementia fairly high nitrogen numbers, ranging up to 30, are frequently found. As such cases would not in any event be confused with anything else, the matter is of no importance from the point of view of diagnosis; but a very interesting observation was made recently which gives the subject a certain importance from another aspect. Case No. 257, not insane, was operated on for senile gangrene, he being aged 78. His nitrogen number was, however, only 21. I have records in two other cases, aged 68 and 72 respectively, of patients not insane and having practically normal nitrogen numbers (21 in each case).

It would seem, therefore, that there is a difference between secondary dementia and mere senility, and this leads to the conclusion that the acute mental condition which preceded the dementia must have had some physical basis in spite of the fact that neither by the method described in this paper nor by any other has that physical basis yet been discovered.

I am under obligation to my colleagues, the medical superintendent and the present and former assistant medical officers of the hospital, for the clinical information and for the collection of specimens. I have at all times had the advantage of their willing co-operation, without which, indeed, the work could not have been carried out.

POISONING BY BUTTER OF ANTIMONY.

BY

WILLIAM BELL, M.D., M.R.C.P. ENGL.,
BRADFORD.

COMMERCIAL antimony chloride, commonly called butter of antimony, contains an excess of acid, which gives it a power of corrosion additional to that effected by the antimony ions, which are readily separated. The effect on the bare fingers of handling the stomach in the case here recorded was similar to that produced by a moderately strong solution of hydrochloric acid—tingling and a sensation of intolerable heat.

On September 16th, 1918, I saw at his house a farmer, who was said to have "fallen into a dyke." I found him, a man aged 46, in bed upstairs at 9 a.m. He had been found lying in a flooded stream about a hundred yards away, conscious, with his head above water. Urged and assisted by his wife, he had walked home and been put to bed. He was shivering; his skin was very cold and livid all over; his pulse was rapid and full. He lay with eyes closed, but he opened them and put out his tongue when ordered. The former were congested, and the latter coated heavily with a harsh white fur. There were no marks about the lips. He was groaning and attempting to vomit. Hot bottles were obtained, but his great restlessness made it difficult to cover him warmly. His appearance at first was simply that due to exposure to cold, but the retching suggested something more, and this impression was deepened by his inability to swallow some warm milk, which he coughed back, clenching at his throat as if the attempt hurt him greatly. Violent retching ensued. Further inquiries elicited the following:

He was seen by his wife about 6.20 a.m., but not again till 8 a.m., when she found him at the stream. About his face was dark brown and slimy vomit, which his wife wiped away with her apron. He walked home and vomited some yellow-stained mucus on to a towel, which, with the apron, was shown to me. He had had no food before leaving the house. Near to a railing, which he had crossed a few yards from the stream, was found a bottle labelled "Butter of Antimony." The bottle and its contents were identified by a chemist, who said the patient had been in the habit

of purchasing two ounces of butter of antimony at a time for treating a horse's foot. The bottle contained 10 fluid drachms.

By 11 a.m. the patient was much worse: the pulse much weaker, the skin still cold and livid, the stomach the seat of burning pain. He died at 3 p.m., seven hours after he had been found, and probably a little over eight hours after he had swallowed the poison.

An autopsy was performed at 2 p.m. the next day. Rigor mortis was extreme. The body generally and the various organs appeared quite healthy except for changes produced by an irritant or corrosive poison acting rapidly. Therefore reference will here be made only to the parts on which the stress of the injury fell. On the abdomen being opened the stomach bulged forward, a striking object deep red in colour. A few coils of small intestine were injected a bright red on their anterior surfaces. There was a small bright red stain on the great omentum adjoining the greater curvature and another stain at the duodenal junction, which looked bruised. The whole outer surface of the stomach was plum-red. Its contents were 20 ounces of dark, almost black, fluid, like charcoal powder and water thoroughly mixed. After being washed almost the whole inner surface was black. It could be scraped away, as could moist dense cardboard, with considerable force. It was not rough and there was no perforation. The mucous coat had been transformed by charring into friable material and its surface shed.

As to the quantity of the poison taken, from the statement of the chemist it would appear that it could not have been more than 6 drachms. Recoveries from 4 or 5 drachms (by a boy aged 12 years) and from 1 fluid ounce have been recorded. In the present case, being empty at the time of administration, the stomach was vulnerable. The subsequent ill effects were intensified by the man's action in lying in a cold stream, probably for a considerable time. One may imagine that, planned or impulsive, his procedure was to rush to the stream to slake his burning in the cool water. By so doing he would provide a rapid diffusion of a strong irritant over the interior surface of the stomach and also liberate free acid.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DIFFERENTIAL DIAGNOSIS BETWEEN CEREBRAL HAEMORRHAGE AND DIABETIC COMA.

The following case is worth recording as it illustrates how easily an incorrect diagnosis may be made between cerebral haemorrhage and coma from diabetes. The case is "complete," for it was followed from the onset to a complete *post mortem* examination.

A woman, aged 72, was admitted to hospital at 6 p.m. on November 29th, 1921, in deep coma. Her son stated that she had always had good health, and in fact had never had a doctor as far as he knew. He returned home at 5 p.m. on November 29th and found his mother lying on the kitchen floor: there was a strong smell of gas in the room, and the tea things were laid, the lid of the kettle being on the floor. A doctor was called in and he sent the patient to hospital at once.

On admission the patient had a temperature of 97°, pulse rate 88, respiration rate 28. She was in a deep coma; the breathing was stertorous, the cheeks puffing in and out. Both pupils were pin-point and equal; there was very slight reaction to bright light. A small cataract was present in the left eye. The breath had a faintly sweetish smell. The heart and lungs were normal; the blood pressure was 155 (systolic) and 130 (diastolic). The arms and legs were very rigid; all reflexes more brisk than normal, particularly the knee-jerks; there was incontinence of urine. The differential diagnosis at this stage appeared to be between carbon monoxide poisoning, cerebral haemorrhage, and diabetic or uraemic coma. A catheter was passed and ten ounces of urine withdrawn and examined. The urine was acid, specific gravity 1005; sugar ++ (Fehling and Benedict, immediate reduction); acetone and diacetic acid ++ (iron perchloride and Rothera test). A diagnosis of diabetic coma was made, and the patient was treated for twenty-four hours with soda bicarbonate and subcutaneous salines.

On November 30th her condition seemed the same; the urine contained no sugar, but acetone was present in a considerable quantity. On December 1st there was a marked change: the rigidity was replaced by flaccidity in the arms and legs; the reflexes of right arm (biceps, triceps) were very brisk; all other reflexes were absent; the urine still contained acetone, but no sugar. The diagnosis was therefore changed to cerebral haemorrhage. On December 2nd the patient died; the pupils were equal and pin-point; the temperature rose to 102°.

On *post-mortem* examination of the brain blood-stained fluid oozed out of the stalk of the infundibulum. There was an enormous haemorrhage into the basal ganglia and internal capsule of the left side. There was so much destruction of brain tissue that it was impossible to state the exact site of the original haemorrhage; a large clot was present in the distended left lateral ventricle. The third ventricle and right lateral ventricle both contained blood-stained fluid, but no clot. They were not distended. The fourth ventricle contained no blood and was not distended.

The thoracic and abdominal aorta showed considerable arterio-sclerotic changes, with many calcareous plaques of varying size. The kidneys were arterio-sclerotic; the right weighed 3½ oz. and the left 2½ oz.

There are records of acetone being found in cases of cerebral haemorrhage, but I can find no cases in which sugar in considerable quantity was present. Puncture of or damage to the floor of the fourth ventricle should give rise to glycosuria, but there was no evidence of this at the autopsy.

Wolverhampton.

THE ANTE-NATAL TREATMENT OF CONGENITAL SYPHILIS WITH SALVARSAN AND MERCURY.

The following results were obtained at the Royal Infirmary, Sunderland, in the years 1920 and 1921:

Year.	Mothers treated for Syphilis.	Babies born Alive.	Result of Repeated Wassermann Tests.		Babies Dying of Syphilis.	Deaths of Foetus.
			Positive.	Negative.		
1920	10	10	3	7	0	0
1921	7	7	1	6	0	0

These cases were all treated as out-patients. Most of them were confined in their own homes, and brought their babies for examination about a month after birth. A Wassermann test was done on the babies about the first, third, and sixth months, but occasionally the periods varied, one case, for instance, having been tested for the first time one year after birth.

Dr. Findlay's results encourage one to hope that not only will the "negative" baby remain negative, but that the mothers will continue to bear non-syphilitic children.

NOEL F. ROWSIRON, M.D.

Honorary Physician, Royal Infirmary, Sunderland.

THE TREATMENT OF EARLY CASES OF CHOLERA WITH VOLATILE OILS.

I wish to record a form of treatment which in the course of many years I have found not merely beneficial, but certainly curative in the early stages of cholera. Many years ago, placed in the midst of a severe and widespread epidemic of cholera, I met a gentleman who told me of what he called a "certain cure" for cholera, consisting of grated nutmeg in rum. I had opportunities of watching the effect of this in a good many cases; the early ones were cured immediately, the disease being apparently aborted. On reflection I was convinced that the beneficial effect of the nutmeg was due to its volatile oil, which probably had a bactericidal effect on the cholera vibrios in the duodenum and small intestine. I then found in the camp hospitals a "pro diarrhoea mixture" supplied by the medical stores which contained approximately 28 per cent. of the volatile oils of cajuput, aniseed, and juniper in equal parts, tincture of cinnamon 50 per cent., and ether alcohol and aromatic sulphuric acid about 22 per cent. I tried this for cases of cholera in 40-minim doses, containing about 12 or 15 minims of the mixed volatile oils, at half-hour intervals, and the reports I got on the effect of this mixture were most favourable. Since then I have had opportunities of watching the effects of the treatment of cases of cholera with volatile oils in three different years, and in early but typical cases of cholera, whether oil of cloves, or cinnamon oil, or the mixture of four oils previously mentioned was given, the disease was invariably aborted.

In two cases that I can call to mind cholera vibrios were isolated in the central laboratory at Baghdad. These cases were given one or two doses (12 minims) of oil of cloves before being transferred to the isolation hospital; they were walking about the following day, and saline infusions were not found necessary on their arrival.

Very recently nine cases having the clinical appearance of cholera have been brought to the military cholera hospital here during the existence of a mild epidemic in the vicinity. In some of these a bacillus resembling the cholera bacillus was found, but not giving the correct cultural reactions. The first case, treated on ordinary lines with saline infusion, etc., died. One other died ten minutes after admission. The other seven, treated with oil of cinnamon in 12-minim doses, supplemented, in several cases that were collapsed, with saline infusions, recovered.

A fact that tends to convince me of the benefit derived from these volatile oils in early cases is that the patients say immediate relief has been obtained. Assuming, then, that certain volatile oils known to have antiseptic properties are curative

in the early stages, the manner in which they act requires explanation. To me it seems probable that, being mostly insoluble and unabsorbable in the stomach, they pass on into the small gut, where such easily destroyed organisms as the cholera vibrio would be killed or rendered inert. I do not suggest that the administration of these volatile oils is of considerable value in the advanced collapse and toxæmia stages of the disease, though any effect they may have in the destruction of cholera germs lingering in the small gut should not be ignored, especially as their administration is harmless. When these conditions are established the administration of saline infusions is imperative.

G. O. F. SEALY,

Indian Station Hospital, Feroz-pore

Lieut.-Colonel I.M.S.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH-WESTERN BRANCH: EXETER DIVISION.

A CLINICAL and pathological meeting of the Exeter Division of the British Medical Association was held jointly with the Devon and Exeter Medico-Chirurgical Society on Friday, May 19th, in the library of the Royal Devon and Exeter Hospital. There was a wealth of excellent material in the shape of cases, pathological specimens, and radiographs. Dr. VIELAND showed a case of syphilitic paronychia successfully treated with salvarsan. Dr. FOULKES showed an interesting case of compound palmar ganglion. Dr. BARTLETT showed a specimen of ruptured left ventricle of the heart from an epileptic patient. Mr. DYBALL showed a fine specimen of tuberculous hyperplasia of the colon. He described the condition of the transverse colon at the operation as resembling an intussusception, very hard and thick. The colon after removal was found to be filled in the transverse portion with papillomatous masses, with patches of extensive ulceration; the patient is making a slow but good recovery. Mr. DYBALL also showed a specimen of twisted ovarian cyst with an adherent inflamed appendix, and several others. Dr. GORDON described and Dr. SOLLY showed specimens from a case of chloroma. Dr. ROPER showed and discussed a case of leukaemia. Mr. CANDLER showed two cases of septic infection of the knee-joint treated with injections of ether, with complete recovery of function; also an enlarged prostate with a large calculus embedded in the urethral orifice. Mr. NORMAN LOCK showed skiagrams of two cases of severe deformity of the femur resulting from gunshot wound and fracture respectively corrected by open operation and plating; also a series of skiagrams illustrating diseases and deformities of the hip-joint.

Reports of Societies.

ICTERUS NEONATORUM.

At a meeting of the Edinburgh Obstetrical Society held on May 10th, with the President, Dr. LAMOND LACKIE, in the chair, Dr. FARQUHAR MURRAY read a communication on *icterus neonatorum*. The paper was the outcome of observations on a series of babies, 68 per cent. of whom developed jaundice. These showed that the jaundiced state commenced twenty-four hours after birth in the majority of cases, and rarely lasted more than a week. It was deleterious to the child, and a late onset (second, third, or fourth day) presaged a milder attack. Comparison of birth-weight with incidence of jaundice showed that there was a relationship—small babies being specially liable—which suggested that the "serum content" decided whether jaundice appeared or not. A deficiency favoured, while an abundance was antagonistic. To prove this babies of similar birth-weight, which had been separated early, were compared with those where the cord had been ligatured at the routine time. The former showed a definitely higher percentage incidence of jaundice. Cases in which the serum content was increased by stimulating the baby to aspirate as much blood as possible, or by the actual injection of serum, showed the best results. Sex, the umbilicus, and the method of feeding were excluded from the etiology, while the idea that the jaundice was due to destruction of superfluous red blood corpuscles was also dis-

counted. Cold was a predisposing factor, but prematurity and asphyxia were causes, in that the babies started life with a subnormal blood content. Dr. Murray was of opinion that the observations pointed to haemolysis as the initial cause. The serum content was a deciding factor. He ventured to suggest that the haemolytic agent was the result of the metabolism of fats during the early days after birth while the baby was living on its own food reserve prior to the establishment of breast feeding. The practical suggestions of the paper were the importance of assuring that the baby got its maximum blood supply before ligation of the cord and the possible therapeutic value of a blood transfusion or injection of serum in jaundiced and premature babies.

Omphalorrhagia.

Dr. DOUGLAS MILLER read a paper on omphalorrhagia, with a record of two cases. These two cases had been the only ones occurring in the Edinburgh Maternity Hospital for a number of years. They occurred at the same time, and occupied adjoining cots in a small ward. One died, while the other recovered. The former was a full-term female, healthy at birth and until after separation of the cord on the eighth day, when a sharp haemorrhage occurred from the stump. In spite of treatment by local application of adrenaline, and ethyl chloride freezing, invagination of the stump with a purse-string suture, acupressure, injection of 20 c.cm. normal horse serum, and finally of 10 c.cm. fresh citrated blood into the longitudinal sinns, oozing continued and ended fatally. The coagulation time estimated by Wright's method was 7½ minutes. In the other child which recovered the coagulation time was 15 minutes. Nothing abnormal was discovered at autopsy, but the organs yielded a pure culture of a coliform organism. As regards etiology, syphilis was certainly excluded, as was haemophilia by the sex, absence of family history of such, and by the late onset. The most probable cause in the speaker's opinion was general sepsis. With regard to treatment he advocated the early introduction of 100 to 150 c.cm. of citrated blood from the parent into the external jugular vein or superior longitudinal sinns, as being more important than local measures.

Specimens.

Professor R. G. McKENNON (Aberdeen) showed a specimen of chorion-epithelioma extending into the right broad ligament and involving the ovary. The patient was aged 23 and in July last expelled a hydatidiform mole. As bleeding persisted the uterus was curetted, but irregular pyrexia continued till the end of August, when a mass was found in the abdomen extending up to the umbilicus, accompanied by signs of pelvic inflammation. Three days later an abscess burst spontaneously above the pubis and a large quantity of offensive pus was discharged, with rapid diminution of the abdominal swelling. She was discharged from hospital on September 23rd with her condition considerably improved. Bleeding soon recurred and persisted more or less continuously till the end of February, when she noticed blood-stained expectoration. The uterus was then enlarged to the size of a 3½ months' pregnancy, and after dilating the cervix an irregular growth could be felt in the anterior wall of the uterus. Microscopic examination of a scraping showed chorion-epithelioma. Three days later her temperature rose to 103°, she became steadily worse, and died on March 10th, two weeks after the uterus was curetted.

Dr. FARQUHAR MURRAY (Newcastle-upon-Tyne) showed a specimen of secondary abdominal pregnancy following incomplete tubal abortion. The patient was aged 39 and gave a history of seven months' amenorrhoea. There had been three attacks of pain—at the seventh week, fourth month, and two weeks before admission. At no time had there been vaginal bleeding. The foetal limbs could be felt as irregular nodules in the pouch of Douglas. On opening the abdomen the foetus was found enclosed in an amniotic sac covered with fibrin and containing little fluid. The placenta was contained in a distended tube, through the dilated ostium of which the cord and amniotic membrane passed. The foetus, which showed deformities of hands and feet, had reached six months' development and lived and breathed for three-quarters of an hour after removal.

Dr. MURRAY also exhibited a specimen of a two months' pregnancy in a rudimentary uterine horn which was attached to the main part of the uterus by a narrow pedicle. Sections of the pedicle showed no evidence of any communication.

TOWN-PLANNING AND THE MEDICAL PROFESSION.

A meeting of the Oxford Medical Society, held at the Grosvenor Hotel in May, Captain R. L. Reiss, Chairman of the Garden Cities and Town-planning Association, opened a discussion on "Town-planning and the medical profession." He said that town-planning was really a most important branch of medicine. The medical profession agreed that bad housing, and particularly the bad surroundings of houses involving a deficiency of sun and air, militated against health and led to the spread of infectious diseases. It was unnecessary before a professional audience to enlarge upon its effect upon such diseases as tuberculosis. It was not merely, however, the density of houses in our towns, but the lack of any separation of industrial and residential areas which had a bad effect. The smoky atmosphere, the continuous noise and noxious fumes, all played their part in producing a C3 population. In particular they had a substantial effect upon infant mortality and child welfare generally. It was true that certain causes of infant mortality could be prevented, at any rate with our present knowledge, by proper town-planning and the proper lay-out of housing schemes, but our experience at Letchworth showed that infant mortality could be substantially reduced where a town was healthily planned and where the residential and industrial areas were separated. The infant mortality at Letchworth was an average of 30 as compared with the average of 100 in our larger towns. He recognized that the excessive infant mortality in large towns was not all directly due to bad housing conditions, but when direct and indirect causes were taken into account it was substantially true to say that infant mortality was so caused. Poverty, drunkenness, lack of cleanliness in personal habit, all played their part in producing bad health, but they in their turn were in a great measure due to the slum conditions under which such a vast majority of the population lived.

Whilst town-planning was of supreme importance as a measure of preventive medicine, it was also very important from the economic point of view. The haphazard development of our towns by which factories and houses were mixed up together was not merely bad for the health of the residents, but uneconomic from the industrial point of view. For example, in the east end of London rows and rows of small houses were found near the docks, and as a result factories had to be located away from the river and a large amount of unnecessary transport was caused, a fact which also militated against the amenities of life of the residents near the river who lived in streets continually traversed by heavy drays and lorries.

Town-planning did not merely mean the laying out of a town on satisfactory lines with separate properly planned industrial and residential areas, with open spaces and a limitation of the number of houses to the acre. There was a further consideration which had to be taken into account. Even if a town were well planned there was a limit of size beyond which it was undesirable to go, undesirable as regards amenities of life of the residents and also from the economic view-point. To-day, in London, the worker had two alternatives before him, either to live in the centre in a slum area near his work, or to live in comparatively healthy surroundings on the outskirts and to travel long distances daily to and from his work, thus involving himself in a considerable waste of money, time, and nervous energy.

When Captain Reiss served on the Unhealthy Areas Committee, presided over by Mr. Neville Chamberlain, M.P., he heard a large amount of evidence from medical officers of health in London to the effect that it was very nearly as bad for the health of the worker to live in healthy surroundings on the outskirts and to travel in overcrowded conveyances to and from his work as it was to live in the slums at the centre. The ideal to be aimed at, therefore, was to have a number of towns varying from populations of 30,000 to, say, 100,000 or possibly even 150,000, properly planned and with a limitation of size, surrounded by an agricultural belt. Such a town existed at Letchworth and was in process of building at Welwyn Garden City.

There remained, however, the problem of how to deal with our existing towns. In the case of the largest towns, every effort should be made to prevent further continuous extension. This could be achieved by the starting of new towns in the open country on similar lines to Letchworth and Welwyn Garden City, and so decentralizing both industry and population. The effect of this would be to drain the

congested areas in the centres of our big towns. Something more was needed, however. In the case of the town of moderate size, under the Town Planning Act the Council had the power and the duty to prepare a town plan for the portions of its area not built upon.

Of course, be only a half-measure as compared with what had been done at Letchworth, but would provide that at any rate future development should be economic and should provide for the proper separation of residential and industrial areas and also for the maintenance of open spaces. The older parts of the town could be gradually remodelled, slum areas cleared, the population diminished, and open spaces provided. This, however, would be a gradual process. The point which Captain Reiss specially emphasized was that it should be done on a well thought out plan for dealing with the town as a whole, and not merely as a problem for clearing a small area *per se*. Comparatively small results had been obtained in London by the clearing of such areas in the past, owing to the London County Council having dealt with areas by themselves and not as a part of a whole. Further legislation should also be pressed for, to enable town councils to prepare re-planning schemes for their existing areas, which would provide not merely for the clearing of slums but also for the gradual re-planning of the rest of the town. This would not involve pulling down buildings straight away but merely that when buildings were pulled down the land should only be utilized again in accordance with the plan. Thus there would be industrial zones and residential zones. Any residences in the industrial zone would not be pulled down at once, but the land on which they stood would have to be utilized only for industrial purposes if at any time the houses were pulled down. Such a measure had been introduced in certain of the American cities with good results.

In conclusion he urged upon the medical profession the supreme importance of making their voice heard with regard to these matters. Much of the work of health committees and medical officers of health was at present stultified by the lack of proper town-planning measures, and if only the medical profession urged the public to realize this and to realize the enormous waste in health and money caused by bad planning, there would be much value to be obtained and rapid progress in the future would be made.

The address was followed by a spirited discussion.

BRAIN TUMOURS.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, held on April 21st, with the President (Dr. A. R. PARSONS) in the chair, Dr. V. M. SYNGE showed specimens from two cases of brain tumour. The first case was that of a girl, aged 9, who had been ailing for eight months, being out of sorts and suffering from weakness of the right leg, followed in a short time by weakness of the right arm and by squinting in the left eye. During the eight months she had vomited on three or four occasions, but never complained of headache. A week before admission to hospital she suddenly lost the power of speech and could only swallow with difficulty. The child appeared wasted and neglected, the right arm and leg were paralysed, both knee-jerks were exaggerated, Babinski's sign was present on both sides, there was no ankle clonus, and sensation appeared normal. Abdominal reflexes were present, there was incontinence of faeces, and at times retention of urine; the left facial and left abducens nerves were paralysed. The pupils reacted normally, there was slight doubtful nystagmus in the left eye; the tongue could not be protruded, there was paralysis of the left side of the soft palate, pharynx, larynx, and left vocal cord. The patient could not speak and could not swallow, Kernig's sign was present, and flexion of the head on the trunk produced pain; the chest showed signs of bronchopneumonia. The child died a few days after admission to hospital. The post-mortem examination revealed a large tumour involving the left side of the pons, medulla, and cerebellum; it proved on section to be a sarcoma. The second case was that of a girl, aged 20, who had suffered from headache and vomiting for two months; she had double choked discs and well-marked nystagmus. Subsequently all the signs of cerebellar tumour developed, and death occurred four months after the onset of symptoms. The post-mortem examination showed multiple tuberculomata of the left lobe of the brain.

Dr. F. C. PURSER reported a case of meningitis (with the characteristics of tuberculous meningitis) who had made

a slow but complete recovery. Mr. BUANE showed *post-mortem* specimens from a case of lymphatic leukaemia, with moderately enlarged spleen and greatly enlarged lymphatic glands. Dr. W. F. LAW reported three cases of hypothyroidism, all of which recovered completely on treatment with thyroid extract.

At a meeting of the Tuberculosis Society of Great Britain, held at the Margaret Street Hospital on May 22nd, with Dr. DE CARLE WOODCOCK in the chair, a discussion was opened by Dr. WILSON on "The therapeutic measures for the relief of pulmonary tuberculosis, especially in relation to dispensary treatment." He considered that as tuberculosis officers had given more time to the subject, and had a more accurate knowledge of the pathology and conditions of the disease than the general practitioner, they would in most cases be able to give greater relief. In his opinion to give cough mixtures to tuberculous cases was harmful to the digestive system. He then described the methods by which he had obtained the best results. He had found ammonium picrate the best general tonic; he emphasized the value of calcium salts in general treatment, and recommended bismuth in large doses for diarrhoea. Colonel GUNTER exhibited charts showing the results of tuberculin treatment. Theoretically, tuberculin was the right remedy, and it had been pushed a good deal. Much remained to be known as to the correct groups of cases to which it could be satisfactorily applied; one group in which it was most valuable was the asthmatic. In the course of the discussion there was a good deal of criticism on the action of the Ministry of Health in attempting to restrict tuberculosis officers to making diagnoses and to instructing the general practitioner in the conduct of treatment. The general view was that the position adopted by the Ministry was detrimental to the best interests of the public, and absurd on the ground that it set up specialists and then refused to use their special knowledge.

Rebicus.

GARRISON'S HISTORY OF MEDICINE.

DR. FIELDING GARRISON'S *Introduction to the History of Medicine*¹ holds a place by itself among medical textbooks—somewhere, let us say, beside Allbutt and Kelleston's *System of Medicine*. In explaining why historical matter had been omitted from his *System*, Sir Clifford Allbutt wrote: "To trace the living waters of the healing art and the auxiliary sciences in their secret channels under the foundations of the temple, of the gymnasium, of the museum, or of the marketplace, until they burst forth once more in the time of Vesalius, of Harvey, of Morgagni, of Haller, of Hunter, of Bichat, of Bernard, of Laënnec, is not a pursuit for these pages." But in 1896, when this was written, the medical student and the practitioner had no single volume to which they could turn for an adequate summary of the history of medicine. The gap was filled seventeen years later by the publication of Dr. Garrison's admirable book. His official position at the Surgeon-General's office at Washington, within the great storehouse of medical literature—the Surgeon-General's Library—and in close touch with its *Index Catalogue*, gave him unusual advantages for the preparation of a work of this kind; indeed, he describes it as being in a very real sense a product of that library.

We praised this compendious history of medicine on its first appearance, and welcomed the second and enlarged edition which was published shortly after the entry of the United States into the European war. Our admiration is increased by perusal of the third edition, which bears evidence of the most painstaking revision. It is true that the book has grown in eight years from 763 pages to 942; but the added matter has been introduced with due regard for perspective, and the character of the work is unchanged: freshness and individuality of treatment are not spoilt by excess of overlaid material. A great part of the revision has been carried out in order to keep abreast of the large amount of original work done during the past four years in the way of medical historical research. Additions have also been made to the many short biographical notes, illustrated by portraits,

which impart a very human interest to this survey of the progress of medical science.

Dr. Garrison's primary aim in writing an outline of medical history was to stimulate the medical student and the busy practitioner to pursue their own studies, and each subsequent edition has confirmed our opinion that his book is the most readable, and in its own way the most valuable, of medical histories. No medical library, however small, could be thought complete without it. The author's literary skill and wide learning stand out on every page; but beyond this his wealth of bibliographical references makes the book a key to the subject at large. His many English readers will welcome Dr. Garrison as the national delegate of the United States at the International Congress of the History of Medicine to be held in London during the third week of next month.

CARDIOLOGY.

It was with pleasurable anticipation that the reviewer opened Dr. ALFRED WEBSTER's book on *Cardiac Arrhythmia and the Neocardiology*,² for the valuable records in his paper entitled "Cardiac arrhythmia in relation to cerebral anaemia and epileptiform crises," published in the *Glasgow Medical Reports* of 1900, had not been forgotten.

It is, however, a little difficult to discover the motive for this present large volume, but it seems to show a desire to discredit the accepted views relating to arricular fibrillation, heart-block, and other forms of arrhythmia. The author generously recognizes the extraordinary progress in our knowledge of these arrhythmias during the last fifteen years. But towards the end of his book he says that he "is not clever enough to form any distinct idea as to what all this neocardiological talk means"; he admits that "his helplessness only deepens the conviction that the clearer that idea is likely to become the greater will be his dislike both of the thing meant and of the theoretical conjuror who, as he bitterly supposes, is by sophistic tricks trying hard to take him in." The reviewer is forced to entertain a shrewd suspicion that this is just what one of his neocardiological friends has done, judging by his replies to the author concerning the origin of the smaller waves in tracings 1, 2, 3. It looks very like gentle leg-pulling.

The book consists of a running commentary on a very large number of tracings which are loosely grouped. The first series (6 to 58) exemplifies the gradual change from a high-tension pulse to one of hyperdicrotism; then follow some interesting records taken from a patient with Cheyne Stokes breathing. Records of "premature beats" form a fruitful source for dissertation. There is also a beautiful series (310 to 475) from a case showing recurrent attacks of rapid action. Other sections deal with auriculo-ventricular dissociation, or dissociated action, or heart-block, arricular flutter and fibrillation.

Unfortunately, tracings such as those from 310 to 475 are practically valueless in the absence of jugular records, and throughout the author has been content to base his argument and his interpretation of the tracings on the superficial resemblances of various portions of the records one to the other. Such a method is full of danger. It is hard to understand why advantage was not taken of the information to be gained from jugular records; they would have given definite information concerning the activities of the auricles, and this would have made it possible to speak with certainty. It is obvious that the author fails to distinguish clearly between the pulse of arricular fibrillation and that of ectopic beats, and in some instances he confuses the former with pulsus alternans. For instance, he labels 120, 177, 178, 179, 181 as typical examples of fibrillation; the irregularity in 120 is, however, clearly due to premature beats, and that in 177, 178, and 179 is, we judge, the result of premature beats complicated by a tendency to alternation, the latter being accentuated after each extra-systole; 133 is another excellent example of alternation.

The author is frankly bewildered by the "premature beat, so called," which, as he exclaims, "occupies a position of infinite variety," a variety which he still further accentuates by confounding it with the pulsus alternans and with any record of arricular fibrillation to which it may bear a superficial resemblance. The key to the confusion of which Dr. Webster complains lies in the sentence, "Irregularity is merely a matter of degree." There is something archaic about such a statement. An arricle is either fibrillating or

¹ *Introduction to the History of Medicine*. With Medical Chronology, Data. By Fielding H. Garrison, M.D. U.S. Army. Third edition, revised and enlarged. Philadelphia and London: W. B. Saunders Company. 1921. (Roy. 8vo, pp. 942; illustrated. 45s. net.)

² *Cardiac Arrhythmia and the Neocardiology*. By A. Webster, M.D. London: Watts and Co. 1922. (11½ x 9, pp. 195; illustrated. 25s.)

it is not fibrillating, and if the radial records had been complemented by simultaneous phlebograms or electrocardiograms there would have been no place for such phrases as "if this is the pulse of fibrillation," "if the auricle is fibrillating."

Many words are spent in attempting to prove by reasoning based on his tracings that auricular fibrillation cannot coexist with heart-block. This is waste of time, for such a combination has been demonstrated repeatedly by means of the string galvanometer and its existence is no longer a matter of opinion. Little is to be gained, however, by pursuing this line of criticism, but the book produces a feeling of disappointment. Excellent material and clinical enthusiasm have not been put to the best purpose. Dr. Webster gives a remarkable series of sphygmograms, and the absence of their corresponding phlebograms is to be regretted.

The Heart Rhythms,³ by Dr. DUDLEY LAMSON, is a good book and should prove of value to students, practitioners, and teachers. The author's main object is to describe the various rhythms of the heart as a whole and in relation to each other but apart from all other functions of the heart, and also the methods by which they can most easily be recognized. The introduction of the electrocardiograph in 1910 swept away much of the confusion concerning the various forms of irregular heart action and made it possible to tabulate all the possible rhythms. These are not many, but it is essential to have a knowledge of all before a diagnosis can be made.

The book is divided into two parts. The first deals more particularly with the classification of the rhythms. The basis of this classification is the division of the heart into functional areas by means of the electrocardiograph, which renders it possible to classify the rhythms on the basis of the point of origin of impulses. They then fall into four groups: The sino-auricular, the ectopic auricular, the auriculo-ventricular nodal, and the ectopic ventricular rhythms. These four groups are again subdivided and a fifth added—namely, abnormalities of condition in any rhythm. There are several excellent and helpful diagrams in this part of the book, and the ideas are clearly and simply presented.

The second part is devoted to a consideration of the different instruments for recording the heart rhythms. There is a brief account of the electrocardiograph. From an electrocardiogram it is possible to obtain complete data concerning a rhythm, "the rate, regularity, source of impulse formation of both auricular and ventricular beats, the length of conduction time, and the inter-relation of auricular and ventricular beats."

Various forms of polygraph are mentioned and some excellent advice is given concerning the best way of analysing the records. The significance of the various waves in the jugular pulse is discussed. From the polygraph the information obtained is necessarily incomplete; it does not tell us the point of origin of the impulses, but there should be no difficulty in determining the time relations of the systoles of the auricles and ventricles. A number of polygraphic records are reproduced as examples of the various types of cardiac rhythm. The records are good and the explanatory description clear and concise. The author is to be congratulated on having produced an excellent book.

GYNAECOLOGY.

Dr. A. C. MAGIAN of Manchester has contributed yet another to the numerous manuals on gynaecology⁴ which have appeared of recent years. His object is "to place before the general practitioner a readable synopsis of some of the principal diseases peculiar to women." In this limited aim he appears to us to have succeeded, and the book should not be judged according to the standards applicable to a complete and authoritative textbook of the subject. He frankly admits, moreover, that he has "abstracted and condensed much invaluable material" from a score or more of the best known writers on gynaecology whom he names. This candid acknowledgement that his work is in some measure, at least, a compilation disarms a good deal of criticism which might otherwise have been levelled at the book. The subject-matter is just the standard commonplaces as seen through the mind

of one who, we should imagine, is neither a teacher nor a specialist, but who practises gynaecology to a considerable extent. It is quite possible that for this reason the book may find a measure of popularity, because the point of view from which teachers and specialists are prone to present their subject is not always that from which the general practitioner can obtain the most enlightenment.

It is unnecessary to review the book in detail, but certain points may be mentioned. One is the quite unnecessarily numerous illustrations of instruments and apparatus, many of which are in no way peculiar to gynaecology as distinguished from general surgery. The latter part of the book is indeed strongly reminiscent of a surgical instrument maker's catalogue, and there must be scores of pages of paper wasted in these superfluous illustrations. The man who needs pictures to tell him the difference between a Spencer Wells's and a Kocher's artery forceps requires teaching in operative gynaecology other than can be obtained from any book. Wherever Dr. Magian wishes to emphasize points of diagnostic importance he sums them up and tabulates them at the end of a section in rather smaller print, and frames them with bold black lines. From the point of view of arresting attention this is quite good, but the black lines so strongly recall "mourning" or "in memoriam" cards that they give the book a somewhat funereal aspect. We notice with appreciation that Dr. Magian never mentions an authority without stating in a word or two who he was, or is. For example, "Bartholin's gland (Thomas Bartholin; Danish anatomist, 1618-1680)," "Fröblich's syndrome (Alfred Fröblich, contemporary Austrian neuropathologist)." This is distinctly interesting because not a few of the names, both ancient and modern, whose names one meets with are to many nothing but names. At the same time this practice requires to be most accurately carried out, and it is doubtful if all the credit for the invention of "Fergusson's speculum" should be attributed to Sir William Fergusson. Another point in which Dr. Magian labours to instruct the reader is in giving in brackets the etymology of all the many Latin or Greek words which are inseparable from technical medical writings. This, again, is a praiseworthy and interesting practice calculated to be instructive to all readers. It is all the more disappointing, therefore, to find that the Latinity of the numerous prescriptions scattered throughout the book is not above criticism. Not that this is by any means uncommon, but it is surprising in the work of one who, in these other respects, shows a desire to be accurate in small things. The illustrations, apart from those of instruments, are good, and the whole format of the book is creditable.

Dr. Magian adds an appendix in regard to some twenty-five preparations which he recommends in his prescriptions. Many of these are familiar as the proprietary compounds of well-known manufacturing firms. The author believes, however, that many of them are quite unknown to medical men in this country, and suggests that because of this there is a tendency to scoff at them. In his experience they have apparently not failed any oftener than some of the best-known pharmacopoeial drugs. Our own impression is exactly contrary. *Omne ignotum pro magnifico*, and clever advertising has before now led to the employment of proprietary compounds to an extent their merits have not always justified. Dr. Magian adds what, in our opinion, would have been better left unsaid:

"If the doctor dispenses his own medicines he can produce with these compounds something quite distinctive that will at all events impress the patient favourably and in this way do good all round. . . . The practitioner will increase his reputation by adding to his drug list a few preparations that are not in common use, and by judiciously letting his patient know that she is receiving special attention."

A FRENCH MANUAL OF ANATOMY.

In the second edition of the manual of human anatomy⁵ by Dr. GÉRARD the original text has been revised and nearly 300 illustrations added. The general arrangement is rather striking since it represents a combination of systematic and regional methods; this places the manual at a disadvantage as a book of reference, but for the student it has most distinct attractions and materially prevents repetition. The inclusion of the account of the joints immediately after the description of the particular bones entering into the formation of the articulations appears to be such an advantage that it would be a benefit to see it adopted in other anatomical

³ *The Heart Rhythms*. By Paul Dudley Lamson, M.D. Baltimore: W. B. Saunders Company, 1921. (Med. 8vo, pp. 100.)
⁴ *Manual of Gynaecology*. By A. C. Magian, M.D. Manchester: French Hospital, London: Wm. Demy 8vo, pp. xiv + 436; 147 figures. 21s. net.)

⁵ *Manuel d'Anatomie Humaine*. By Georges Gérard. Second edition. Paris: Masson et Cie. 1921. (Sup. roy. 8vo, pp. 1280; 4 plates, 1,025 figures. Fr. 75 net.)

textbooks. The descriptions are for the most part concise and lucid, and the more important facts are not obscured by the finer details, since the latter, together with the more significant variations and anomalies, are set out in smaller type after the principal features have been indicated. The manual is comparatively free from inaccuracies, although the actions attributed to many of the muscles will not receive universal approval and the account of cortical localization is not quite in accord with modern research. Although, where necessary, references are made to important papers on special points, most of them are to French literature, and scant attention is paid to work in this country or America.

The manual is very freely illustrated, chiefly by simple line drawings, which are clear, helpful, and effective; a large proportion of them are from special dissections and executed by the author. Some of the drawings and photographs illustrating the osteology section lose much of their usefulness by being too small, and the four coloured plates are hardly of sufficient value to justify the labour entailed in their reproduction. Except in the presentation of a larger proportion of original illustrations than usual and the general arrangement, the book does not offer any special features not to be found in the standard textbooks on human anatomy.

FOCAL INFECTIONS AND INSANITY.

IN his book, *The Defective Delinquent and Insane*,⁶ Dr. HENRY A. COTTON approaches the problem of mental disorder from what is undoubtedly a sound biological basis. He takes the view that mind is related to body as function is to structure; that in the last analysis all disturbances of function must be capable of explanation in terms of physical and chemical changes in the body; and that so-called mental diseases are the reflection of some bodily disorder. Though such theoretical views are quite unexceptionable, the somewhat extreme standpoint which Dr. Cotton here proceeds to elaborate regarding the influence of focal infections in the production of insanity would appear to be in need of confirmation at the hands of other observers before it could be generally accepted. His basic contention is that the most constant factor in the production of the psychoses is an intracerebral, biochemical, cellular disturbance arising from circulating toxins, originating in chronic focal infections situated anywhere throughout the body, and more particularly around the teeth or in the tonsils.

The author has made exhaustive investigations into the question of dental infection in the insane, and has carried out systematically an unusually thorough dental therapy in his cases. His experience leads him to deplore the modern methods of repair and conservation of teeth; he regards such measures as responsible for much concealed foci of infection, and as seriously detrimental to the health in a number of instances. He advocates that every patient admitted to a mental hospital should have the teeth radiographed; infected, impacted, and unerupted teeth removed and the sockets curetted; and, whether x rays reveal infection or not, the extraction of any devitalized teeth. These contentions are supported by references to a number of cases, and a series of excellent radiographs, photographs, and drawings of infected teeth are reproduced. Though perhaps Dr. Cotton has over-emphasized focal infection as a causal factor in mental disorder he has certainly drawn attention to a condition hitherto much neglected in asylum cases, and his book should be of service in this respect. There is much in the volume which deserves careful study, and the researches included therein may be regarded as a definite contribution to psychiatry.

NOTES ON BOOKS.

THE lower slopes of Parnassus are often the most pleasant to browse upon, and Dr. HABBERTON LULHAM's new volume of light verse, *Kettle-Songs*⁷ (one third of which appeared originally in *Punch*), is in the true tradition of Calverley and Locker-Lampson. His verses are polished and witty, with a pleasant touch of sentiment, and they do not sacrifice quality to technique, as some light versifiers seem inclined to do to-day. Dr. Lulham's subjects are delightfully varied. He sings merrily of the joys of country life and the "shady side of dear Pall Mall," golf and gipsies, the *Blessed Lexicographer*

as a bedside book, watchmaking, annts and babies, dentists, the bedside manner, and the intermittent pulse—

"You mean it merely drops a beat or so,

A sort of syccopated pit-a-pat?

But, my dear fellow, surely you must know

That's good old rag-time! Oh, I don't mind that!"

We recommend Dr. Lulham's volume to our readers as a tonic to prescribe for convalescents.

Dr. CABANES and his friend Dr. WITKOWSKI have made a collection of stories about doctors and their patients, and have published them in a volume with the title *L'Esprit d'Esculape*.⁸ They have classified them in three chapters: the first containing witticisms, generally at the expense of their doctors, uttered by more or less celebrated patients; the second, retorts by doctors, including some of their candid observations about each other; and the third, quotations having a more or less distinct medical flavour, drawn chiefly from the inexhaustible mine of French diarists and letter writers, but not ignoring the writings of some of our own countrymen. There are a number of illustrations, including several after Hogarth and Rowlandson. It is not a book that can be made the subject of a serious review, for it is not a serious book. It seeks to do no more than amuse, but in this it succeeds.

We have received for review a copy of a small book entitled *Safe Marriage*,⁹ by ETTIE A. ROUNT—a lady whose fine record of service for the troops during the war, and for the civil population in France after the war, is known to us and to many of our readers. As the title suggests, her theme is the prevention of venereal disease and the prevention of conception, and she is quite frank in acknowledging that physical means directed towards the first end must in some degree be directed towards the second also. In her treatment of both matters she is no less frank; but she avoids altogether the air of ecstatic sloppiness with which some writers on sexual relationship seek to embellish their frankness. We fully recognize the importance of sex knowledge, but if we may say so without offence, the pendulum seems to us to have swung a little too far away from over-reticence, so that in the present day the lay public is, if anything, overdone with popular works on the congress of the sexes in man. Having expressed this opinion we should add that the little book on venereal prophylaxis and contraceptive technique now before us is (with the possible exception of a phrase or two on page 46) unexceptionable in taste and tone. Many readers will disagree with the author's point of view, and some will feel grave misgivings about the effect of her teaching; but none can doubt the sincerity of her purpose. Medical men and women who read the pamphlet with an open mind will probably gain something by so doing, and will certainly recognize it as the work of a serious student of two great social problems. Miss Ettie Rount is rather contemptuous of the England of to-day, and more than doubtful of England's future; but with all their faults Englishmen admire "a plus quantity," and the more so when they find it in the work and character of a kinswoman from overseas.

A useful little annual, now in its fifteenth year, is compiled by the travel editor of the *Queen* newspaper.¹⁰ Besides giving a considerable amount of miscellaneous information useful to tourists, the book contains short notes about most of the home and Continental resorts likely to be visited by the ordinary English traveller, the various places being grouped in alphabetical order under the names of the principal countries. The volume is neatly printed and can be carried comfortably in an overcoat pocket. Inexperienced travellers, in particular, will find it helpful, as a preliminary to studying the more comprehensive guide-books to the several districts.

MESSRS. GEORGE ROUTLEDGE AND SONS are preparing a Modern Chemistry for the use of post-graduate readers in a series of volumes, written by authorities in the several departments. The series will be edited by Sir William A. Tilden, D.Sc., F.R.S., Emeritus Professor in the Imperial College of Science, and Professor J. C. Phillip, D.Sc., F.R.S., Professor of Physical Chemistry in that College. The first volume, on the metastability of matter, will be written by Professor Ernest Cohen of the Van 't Hoff Laboratory, Utrecht; the second will be by Mr. Oscar L. Brady, D.Sc., of University College, London, on oxidation and reduction in organic chemistry; and the third by Professor T. M. Lowry, F.R.S., of Cambridge, on physical aspects of organic chemistry.

A HALF-CENTURY OF PUBLIC HEALTH IN NORTH AMERICA.

BY

JOHN C. McVAIL, M.D., LL.D.

(Continued from page 882.)

IV.

WATER PURIFICATION.

The investigations into the purification of public water supplies made by the Massachusetts Board of Health are well known and highly valued in this country, but from the article on the subject contributed to the Jubilee volume by Professor George E. Whipple, who occupies the chair of sanitary engineering in the Harvard Engineering School, it would appear that though great progress has been made water purification is not yet adopted to the same extent in America as in Britain.

The prevalence of typhoid fever after the civil war seems to have been the first factor in causing serious attention to be given to the need for water purification, but the problem in America is not identical with ours. Some of the great rivers which yield a public supply are very muddy, notably the Mississippi, and methods of filtration vary with the circumstances. Sand filters and mechanical filters both have their sphere of usefulness; broadly speaking, the former is used for the clearer waters, the latter for those with much suspended matter. Aluminium sulphate was first used in 1884, and both coagulation and sedimentation are applied in connexion with some schemes of mechanical filtration. The first large installation for slow sand filtration was brought into use at Albany in 1899 for the water of the Hudson, and three years later the first modern mechanical filter on a large scale was adopted by the East Jersey Company to purify the waters of the Passaic river. It is found that while sand filters cost more to establish, mechanical filters cost more to operate. The increase in mechanical filters has been rapid owing to the fact that many waters require purification by coagulation.

Processes supplementary to filtration differ according to the character of the waters; for those deficient in oxygen aeration was in use even earlier than filtration. It helps also to remove odours due to microscopic organisms. Artificial aeration is resorted to on a large scale for the Catskill supply to New York, and Professor Whipple thinks that the method may come into more frequent use. Sedimentation is an old process, but much remains to be learnt about the rate of subsidence of small particles. Coagulation with alum is also an old process, and it was formerly thought that if the whole of the alum were used up as a coagulant the water would not be adversely affected; now, however, it is believed that the reaction is not complete, and that part is not changed into aluminium hydrate, there being a tendency to increase of acidity. Lime and iron sulphate are used for some muddy waters, and lime and soda, with alum where acidity has to be checked, in very soft waters. Softening processes are found to be costly, and various improvements are being introduced. Coagulation is sometimes used in combination with slow sand filtration. Professor Whipple does not discuss the biological aspects of sand purification. The removal of colour is effected to some extent by natural bleaching during storage, but alum is used also. Often the removal of colour is difficult and experiments are now being made along the lines suggested by colloidal chemistry. For the removal of algae producing an evil odour, aeration, filtration, and copper sulphate in very minute quantities are applied; chlorine also is now much used for purification. Protection of reservoirs from pollution by sewage is often found to need attention, and in some places it has been necessary to drain swamps. The Public Health Association established in 1905 what is now the standard method of water filtration in America.

The general results of the activities of the last half-century may be summarized as follows: In 1870 there was practically no filtration of public supplies; ten years later the total population supplied with filtered water was about 30,000; twenty years later it was ten times as much. In 1900 the population supplied with filtered water had risen to 1,860,000; in 1910 it amounted to 11 millions, and in 1920 to about 20 millions, or about a fifth of the total population of the United States. Altogether more than a third of the population living in towns of over 2,500 inhabitants now use filtered water.

STREAM POLLUTION AND INDUSTRIAL WASTES.

The methods used for the prevention and treatment of stream pollution due to industrial wastes in America present a general resemblance to those in use in this country, but in England they had to be applied earlier owing to the more rapid development of industrial congestion and to the fact that the comparative smallness of our rivers lessens their power of diluting waste material. Certain differences between the two countries in matters of administration may be noted. Dr. Earle B. Phelps, formerly professor of chemistry in the Hygienic Laboratory of the United States Health Service, who contributes an article on the subject to the Jubilee volume, holds that in America "the public health interest is paramount" and "State legislation for the most part also recognizes stream control as a public health function." That can hardly be said of this country in the present day. For one thing, excepting in the special cases of London, Aberdeen, and certain smaller towns, river water is rather avoided for public domestic supplies; upland surface water and deep wells are safer sources. Pollution of a stream is seldom so great as to create serious effluvia, nuisance, though there was a time when the Manchester Ship Canal and the Clyde at the harbour of Glasgow could be called, the one a cess-pool and the other a sewer. It is doubtful whether a tidal harbour like Glasgow's comes under the regulations for the prevention of pollution in rivers, but however that may be the conditions were recognized to be so offensive that they were remedied. Speaking generally, a polluted stream cannot in this country be proved to be a serious menace to health, but it is more or less broadly recognized that in the interest of cleanliness and the amenity of the district gross pollution should be avoided.

Professor Phelps properly points out that the true reason for the comparative failure of early legislative measures against pollution in this country was that "legislation was enacted in advance of any suitable study of possible remedial methods, and especially of their practicability and costs, and then the enforcement of the law was left to local authorities." The interests of local trades sometimes seemed to be opposed to the preservation and purity of the waters of a river, and local authorities were often much too local to be independent. On the other hand, when compulsion was applied it not infrequently resulted in the recovery of waste products, the value of which has gone far, sometimes all the way, towards paying for the outlay involved in purification. Complete centralization of control is undesirable, but the best bodies for the purpose are not small authorities, of whom there may be a dozen or a score on a single river, each ready to excuse itself and to blame its neighbours. A conservancy board for the whole watershed from source to outlet is the recommendation of the most recent Royal Commission, and is undoubtedly the soundest principle that can be followed. As Professor Phelps observes, the essential considerations in any case are the size of the stream, its consequent capacity for dilution of sewage and other polluting matter, and any possibilities it may have for self-purification in its course. The standards of pollution and purification have been altered as the result of experience, and Professor Phelps refers to the studies by himself and others as to the conditions in New York harbour and to the virtual abandonment of the older nitrogen basis and the establishment of the present oxygen basis and putrescibility methods; in this line of advance America and this country resemble each other.

DISPOSAL OF SEWAGE AND REFUSE.

It appears from the article by Mr. Rudolph Hering, D.Sc., Consulting Engineer, New York City, that the principles followed and the methods applied for the disposal of liquid and solid refuse in the United States are essentially similar to those of this country, and have been largely adopted from the practice here, the reason being, as pointed out in regard to some of the other matters dealt with in the Jubilee volume, that the problems had to be tackled in Britain sooner than in America. The conditions, of course, are not identical, and the extensive areas of some American cities relative to their population necessarily affect their schemes, but the differences are not fundamental.

It is surprising to gather that in America some sewerage systems are even yet in private ownership, though Dr. Hering points out that the tendency is all in the direction of municipal possession and management.

It may be noted by sanitarians and house builders in this country that sewer ventilation is obtained by direct

connexion between street sewers and house drains and soil or rain pipes. Dr. Hering writes:

"Artificial ventilation is hardly ever required, because a sufficiently good natural ventilation can be secured simply by providing perforated manhole covers on the street surface and a free and unobstructed passage of air from the street sewers to the house sewers above the roof. The usually different temperature at such inlets and outlets will produce a sufficient air circulation. All house fixtures must be securely trapped."

While European methods for disposal of dry refuse prevail, it is stated that in the smaller towns, chiefly of New England, garbage is used for feeding hogs more systematically and under more effective organizations than before, and with the approval of the United States Government.

From his own experience and the numerous records available Dr. Hering concludes that the health of men engaged in the disposal of sewage and refuse is as good as that of men employed at sewage pumping stations, sewage farms, or among the rag-pickers of Paris, or the men on rubbish reclamation works in America. He thinks, however, that great care should be taken to prevent the conveyance of infectious disease, though "no such danger is expected to arise from garbage before it can breed flies, or from ashes." A committee of the American Public Health Association reported in 1916 that in the best managed cities the work of cleansing streets was little if at all more unhealthily than the average of other labouring occupations.

QUARANTINE.

For the United States, with their high rate of immigration from almost every part of the world, the prevention of disease introduction is obviously a public problem of immense importance.

The article on the subject in the Jubilee volume is by Dr. Hugh S. Cumming, Surgeon-General of the U.S. Public Health Service. He states that American practice is stricter than English, since the former applies preventive measures not only to ships actually infected, but also to vessels from infected ports. These, however, are dealt with as "suspected" vessels in this country and are not disregarded, so that the difference seems to be largely a matter of terminology. The institution of national control has been a gradual process, completed only so recently as March 1st, 1921. Formerly control was local, and officers changed often owing to political influence. Dr. Cumming takes occasion to emphasize the importance not merely of avoiding frequent change of officers, but of securing that those appointed are really competent. The promiscuous selection for the position of quarantine officer of men untrained in the technical duties of the office, no matter how proficient in the general practice of medicine and surgery, is, he considers, a very faulty custom. The object of quarantine in America is the same as here, "the maximum protection of the country with a minimum hindrance to commerce and the least inconvenience to the travelling public." It is claimed that the American system is unique in maintaining a double line of defence—medical examination (through the consulate) at the port of departure as well as at the port of arrival. Dr. Cumming says:

"Officers of the Public Health Service are stationed in the Philippines and in other parts of the Orient, including the coast of China, on the west and east coasts of South America, on the islands of the West Indies, and in all the chief ports of Europe, to enforce sanitary precautions against vessels, cargo, passengers, and crew departing for ports of the United States. Whether it be the fumigation of a vessel at the plague-infected port of Hong Kong in order to destroy rodent carriers of the disease; whether it be the fumigation of a vessel in the yellow-fever-infected port of Vera Cruz for the purpose of destroying mosquitoes on vessels sailing for ports of the United States; or the delousing of verminous passengers from the typhus-infected areas of Europe, this group of Public Health Service men working in foreign countries operates as a tremendous force in safeguarding the ports of the United States from the introduction of quarantinable diseases, and always with but the slightest interference to the travelling public or to the movement of traffic."

The strictly quarantinable diseases are stated to be cholera, typhus, plague, small-pox, leprosy, and, within limitations, anthrax. There is no mention of yellow fever in this list, but obviously it ought to be included, since it is said later on that "the prevention of the introduction of yellow fever during the past sixteen years, despite its almost continued prevalence in Mexico, Central and South America, is a striking testimonial to the system and the personnel composing it." While the endemic small-pox of the States is now an extraordinarily mild disease a highly virulent strain prevails in

vaccinations have been performed along the Mexican border. No mention is made of conscientious objectors. American quarantine of course is not confined to the seaboard, there being about a hundred land stations. It is held that partly owing to prevalence of stegomyia and consequent risk of yellow fever, partly because the water front construction of United States ports is of timber, affording easy harbourage to rats, and partly for other reasons, the United States needs maritime quarantine more than any other civilized country, and the figures given show the extensive scale on which the work is done. In 1920 some two million persons, passengers and crews, brought by 20,000 vessels, were inspected; 5,000, of which nearly 4,000 arrived from infected ports, were disinfected; 47 of them had infection on board. Less than 50,000 persons were detained and disinfected; 4,800 were vaccinated or examined bacteriologically. Typhus fever is prevalent in Mexico, and on that frontier 130,000 persons were deloused and 55,000 vaccinated. At insular quarantine stations and foreign ports over 10,000 vessels were inspected and 1,500 fumigated. The cost is regarded as small compared with the benefit, but the scheme must be continued until the internal sanitary condition of the country becomes so good as to prevent such diseases from spreading.

(To be concluded.)

EPHRAIM McDOWELL.

Dr. AUGUST SCHACHNER, when sending a copy of his book,¹ the subject of this notice, accompanied it with a letter to the Editor emphasizing the view that insufficient honour had been done to McDowell, and that his memory had been clouded over, in particular, if we understand Dr. Schachner rightly, by claims made on behalf of Spencer Wells and his contemporaries. Anyone, therefore, inquiring about Ephraim McDowell (1771-1830), and desirous of obtaining a clear statement of the essential facts without extraneous matter, would be well advised first to read the account of him by S. D. Gross.²

In 1890 McDowell's granddaughter, named Mary Young Ridenbaugh in the first edition, but in subsequent editions Mary I. Valentine,³ published a biography which contained a few of his letters but included many dubious statements and gossip. Whenever the history of ovariotomy has been discussed of late McDowell has been referred to; in 1879 S. D. Gross, Oliver Wendell Holmes, and Spencer Wells⁴ all joined in applying to him the title, "Father of Ovariotomy"; in the BRITISH MEDICAL JOURNAL of July, 1880,⁵ there is a correspondence of historical importance between Charles Clay and Thomas Keith; in the JOURNAL of November, 1884, is the address given by Wells at Birmingham, the title of which should be noted; it was "The Revival of Ovariotomy and its Influence on Modern Surgery."⁶ The centenary of McDowell's first ovariotomy was celebrated in 1909, when D. McMurtry of Louisville styled him "The First Ovariotomist." Mr. Alban Doran contributed a history of the Samaritan Hospital, and Dr. Herbert Spencer called McDowell an American hero, and said that his achievement was a monumentum aere perennius.⁷

In the issue of this JOURNAL for June 21st, 1913 (p. 1333), is a fairly long account of a paper by Dr. Schachner,⁸ and as recently as in November and December last references to McDowell were made in connexion with the address of Sir Harold Stiles by Drs. Fleming, Cameron, and Mitchell.⁹

Dr. Schachner's book contains 314 pages of text, 4 additional pages of bibliography, 11 pages of index in double columns, and 21 illustrations. Chapter I describes how pioneers moved westwards from Virginia into "Kentake," the Iroquois word for prairie or meadow land. With negro labour as a substratum the forests were cleared, wheat and tobacco planted, and traffic by the rivers flowing into the Mississippi developed, whilst the whites fought the Indians and the wolves. Genealogies of early settlers are given, and also the origin of the town of Danville, 500 miles west of Richmond, where McDowell practised.

McDowell was descended from Scottish ancestors, one of whom fought under Cromwell in Ireland and had helped to defend Londonderry against James II. The second chapter relates to McDowell's time in Edinburgh during 1793 and 1794; a point which has worried previous writers as to why McDowell left without taking a degree appears to be decided by a letter written to him there by his father. He stated that he could expend £300, that and no more, upon his son's education abroad. Chapters V and VI include McDowell's

two papers in the *Eclectic Repertory* of 1816 and of 1819.¹⁰ Subsequent chapters contain controversial matter on the history of ovariectomy with repetitions which in the preface are stated to be inevitable; conclusions in the absence of sufficient evidence have to be arrived at by a chain of suppositions.

Among the illustrations are those of McDowell's house, front and back, and of the interior of the annexe in which Dr. Schachner thinks the operation on Mrs. Crawford was done. The house is now occupied by negro tenants and is in bad repair; Dr. Schachner took a great deal of trouble in trying to buy it, but was prevented by the landlord demanding more than double its utmost value.

On the title-page of Dr. Schachner's book there is printed in red: Ephraim McDowell, "Father of Ovariectomy" and Founder of Abdominal Surgery. The inverted commas may be understood to imply that the title given by Gross, Holmes, and Wells is one that is attached to McDowell beyond dispute. The addition, Founder of Abdominal Surgery, might be taken as reiteration for the purpose of emphasis, following the method employed in the Prayer Book; merely as a question of time ovariectomy may be said to have been founded before the operations for intestinal obstruction or appendicitis, with which McDowell's countrymen have had much to do. But Dr. Schachner evidently desires the title, Founder of Abdominal Surgery, to have a wider meaning. One or two criticisms of the way Dr. Schachner has handled authorities may suggest difficulties in maintaining his thesis. McDowell, when in Edinburgh, attended the extramural class on surgical anatomy held by John Bell, who, aided by the artistic skill of his brother Charles, was a most brilliant teacher. But nowhere in John Bell's published writings is there any reference to ovarian disease and ovariectomy; there is no evidence that McDowell heard the subject mentioned in Edinburgh, either by Bell or by anybody else.

The most important contribution made in the eighteenth century is not noted by Dr. Schachner in his bibliography and is only indirectly referred to in the text. The *Mémoires*¹¹ which appeared in 1753, by Le Dran, jun., Mouton, De la Chaud, Montaulieu, Malaval, De la Porte, and Morand, especially that by De la Porte, are reflected in William Hunter's description in 1757, and their recommendations were followed by Nathan Smith in 1821. It is important to compare McDowell's account of his first operation in 1809 with that by Nathan Smith of his in 1821. McDowell is said not to have made notes at the time, but to have written his report after his third operation in 1816, depending upon his ledger for his dates and his memory for his facts. He then stated that he had been called by two medical practitioners to see Mrs. Crawford, who had believed herself to have become pregnant again, and to have gone beyond her time. Operations had been done for what we now know as extrauterine foetation, and had been successful. The incision employed for this was that which McDowell adopted. He made it on the left side of the abdomen, 3 in. outside the left rectus abdominis muscle; it was 9 inches in length from the lower border of the ribs downwards. It was made straight through into the abdominal cavity upon which the intestines prolapsed, as was inevitable when such a long incision was made in a patient not anaesthetized. He tied the pedicle, leaving the ends hanging out of the wound, cut open the tumour, and removed 15 lb. of a dirty, gelatinous-looking substance, then extracted the sac, which weighed 7½ lb., and closed the incision by sutures and strapping, except for the ligature ends. The patient was making her bed five days later, and returned home well after twenty-five days. Mrs. Crawford survived the operation thirty-two years, mostly in good health, and died (as the illustration reproducing her tombstone shows) in 1842, aged 78.

Nathan Smith, professor of surgery at Yale, performed his first ovariectomy in 1821, and described the operation to his class of surgery during the following winter. He published the account of it in two of the most important periodicals of the time, the *American Medical Recorder* of January, 1822, and the *Edinburgh Medical and Surgical Journal* of October, 1822.¹²

Nathan Smith had previously examined *post mortem* a woman who had died after being tapped seven times, and found a cyst without adhesions, only attached by the ovarian ligament. He had also examined two other specimens of ovarian cysts taken out *post mortem*, equally unattached except by the ovarian ligament, although there had been several tapplings during life. His description of his patient's history shows that he could make an adequate diagnosis

beforehand. He had the woman's head and shoulders raised and an assistant pressed the cyst forwards against the abdominal wall; he made an incision three inches in length in the linea alba, from the umbilicus downwards, but only so far as the peritoneum, until the bleeding had ceased. After opening the peritoneum the cyst was punctured with a trocar, and seven pints of fluid were collected, whilst one pint escaped. As the emptying cyst was dragged out only adherent omentum followed—no intestines. Two leather ligatures were applied to omental vessels, and two others in dividing the pedicle. The incision in the abdominal wall was closed completely. There were no unfavorable symptoms afterwards, and in three weeks the patient was walking about. The leather ligatures were the strips of kid which had been previously used in the United States for the ligation of arteries; they were absorbable and rendered relatively free from germs by the tanning. The first successful ovariectomy in England was done in 1836 by Jeaffreson of Framlingham, Suffolk. In the course of thirty years he had watched about 20 cases; in 1833 at a necropsy he had exposed the cyst through an incision 1 in. long and let off fluid with a trocar until the sac could be drawn out, when it proved to be attached only by the ovarian ligament. Having watched his patient from 1833, and knowing of Nathan Smith's case, he followed him, except that he made an incision only 1 in. long, as the French *Mémoires* and William Hunter had suggested. Through it he drew off 12 pints of "clear serum" and in drawing out the sac a small cyst containing 2 oz. was emptied. He put a silk ligature round the pedicle, but cut the ends short. The patient recovered and remained in good health. King of Saxmundham, who assisted Jeaffreson, imitated him except that the incision had to be 3 in. in length; R. C. West of Tonbridge, Kent, and Crisp of Harleston, Norfolk, followed; their cases were all successful.¹³ Subsequently Charles Clay of Manchester in 1842, who had learnt of McDowell's operation through Lizars, began his series of operations by employing the long incision, with the ends of the ligatures hanging out, for cysts as well as for more solid tumours.

In a letter written by McDowell about a year before his death occurs this sentence: "Therefore, it appears to me mere humbug about the dangers of peritoneal inflammation—so much talked about by most surgeons."¹⁴ The early ovariectomists showed that the peritoneum could be very tolerant of injury, yet surgeons knew that following an opening of the peritoneal cavity cases were apt to die in a few days of acute peritonitis. McDowell said that out of 11 he had only lost one, the fifth. Yet the remark of Baker Brown, which Wells reported, was a pertinent one: "It is the peritonitis which beats us." What the peritoneum will tolerate was demonstrated by Pasteur when he drew micrococci in a chain and told the audience that they were the real cause, not those which had been alleged. In the sense of becoming established the practice of abdominal surgery can hardly be said to have been "founded" until the precautions had been added which prevents this peritonitis from beating the surgeon to-day.

SATURDAY, JUNE 10TH, 1922.

"NEW AND NON-OFFICIAL REMEDIES."

THE American Medical Association for the last fifteen years has carried on an extremely useful piece of work by publishing annually a list of the new proprietary remedies which conform to certain simple rules. The reasons which made the American Medical Association take up this work and the results which it has produced are well worth the consideration of the medical public in this country. Probably most medical men here have been disquieted by the increasing tendency for commercial interests to influence or even to dominate therapeutics. Leaving out of account so-called patent medicines, about which medical opinion is probably almost, if not quite, unanimous, the position which has been attained by certain classes of what may be termed the "ethical" proprietary medicines is scarcely satisfactory to those who desire the advance of therapeutics. There is undoubtedly an increasing tendency to introduce to the medical profession by means of advertisement new preparations the value of which is doubtful or unknown. These preparations are "ethical" in that their composition is not a secret, and in that they are not advertised direct to the public; but there is an unpleasant resemblance between some of the "ethical" proprietary preparations and the ordinary quack medicine in the extravagant claims made as to their therapeutic action.

Everyone knows how difficult it is to arrive at a final conclusion on the therapeutic value of any new remedy, but it is instructive to consider the difference in the fate of a new remedy, depending upon whether it is or is not a proprietary article. When a non-proprietary substance such as quinine is applied to some new therapeutic purpose, the value of the remedy is determined by years of patient work, and every fresh fact announced concerning its action is subjected to rigorous criticism. The greater part of such discussions are carried on in scientific journals which circulate almost exclusively among pharmacologists and physiologists, and the medical profession as a whole usually only hears of those facts which have survived the critical testing of many independent observers. If, on the other hand, the remedy happens to be a proprietary article it suffers a very different fate. The first positive results obtained are immediately blazoned forth to the whole profession, whilst any work which contradicts these results is apt to remain in obscurity. If a controversy arises concerning the merits of the preparation the struggle is (to say the least) an unequal one, for a powerful commercial interest advertises one side, whilst it is the duty of no one in particular to call attention to the opposite view. A situation such as this is not favourable to advance in sound therapeutics, and it is important to realize that in this country we have no definite check on the manner in which new remedies are advertised, except the self-respect of the firm which introduces them; this safeguard is adequate in some cases; it is reinforced by the scrutiny to which advertisements tendered to them are subjected by the more responsible medical journals. The disposition has been, no doubt, to rely on the maxim *caveat emptor*; and if the appeal of all drug manufacturers were in truth always only to members of the medical profession, who are skilled judges, there might be less reason to question its

The leaders of the American Medical Association found that the medical press of America was being flooded with advertisements very little better than those of ordinary quack medicines, and they took determined steps to meet the evil. They came to the conclusion that it was useless to try and solve so large a problem by occasionally refusing to advertise a particularly flagrant offender, and they decided to take the positive step of publishing for the benefit of their members an official annual list of those proprietary remedies which conformed to certain simple rules. A council of pharmacy and chemistry was established by the American Medical Association in 1905; it consisted of professors in medicine, pharmacology, and chemistry, assisted by a committee of consultant physicians. The council has laid down ten simple rules to which proprietary remedies must conform, if they are to be included in the approved list. The chief rules are that the remedy must not be secret, must not be advertised directly to the public, and must not be advertised by unwarranted, exaggerated, or misleading statements as to its therapeutic powers. Remedies which conform to these rules are included in the volume *New and Non-official Remedies*,¹ whilst in another volume, *Propaganda for Reform in Proprietary Medicines*,² are published accounts of some of the more glaring scandals in proprietary medicines claiming to be "ethical." The council has carried on this work for fifteen years in the face of steady and persistent opposition and abuse. The effects produced by such an effort as this are hard to measure, for the evils prevented are at least as important as the evils cured.

The American Medical Association states that at the period when it commenced this work there was a marked tendency to turn quack medicines into "ethical" proprietaries. The proprietors found it more profitable to publish some sort of formula for their nostrums, to save the enormous cost of general advertisement, and to advertise only in the medical press, trusting to the medical profession to act as unpaid agents for introducing their products to the public. The simple device of enclosing with their medicines copious advertisements, mentioning all the diseases which the nostrum pretended to cure, was adopted to ensure that after the nostrum had been introduced to a patient by a doctor the patient would continue to use it, and would probably recommend it to his friends.

The American Medical Association believes that the work of its council of pharmacy and chemistry has been of the greatest value in providing an impartial guide to the medical profession in America, and also in checking the exuberance of the imagination of proprietors of new remedies when advertising their wares. The question naturally arises whether any such work is needed elsewhere than in America. The situation in this country is that it is nobody's business to check the claims made in advertisements of new remedies. The medical journals exercise a varying degree of discretion in regard to the advertisements they admit to their columns. But there is no authority which can inform the manufacturer what methods of advertising are acceptable to medical opinion, nor the managers of medical journals what new proprietary preparations are genuine; nor is there any authoritative source of information available to medical men who wish to know whether some new remedy which they see advertised is a reputable one or merely a quack nostrum decked up to suit the supposed taste of the medical profession.

The whole question is a difficult one, since large

¹ *New and Non-official Remedies, 1921.* Chicago: American Medical Association, 1921. (Cr. 8vo, pp. 418. 1.50 dols.)

commercial interests are involved; and it is hardly possible to deal with it piecemeal; if anything is done fixed rules must be laid down and rigorously enforced in all cases. This kind of work naturally arouses violent opposition, and involves heavy expenditure in time, and a certain expenditure in money, since laboratory analyses are necessary.

THE REPORTING OF THE SECTIONS.

AFTER the feast, the reckoning. After the feast of reason at the Sections of the Annual Meeting, the recording of the wisdom distilled or to be distilled from the words uttered. There will be nineteen Sections at Glasgow, and between them they are to hold forty sessions, each of about three hours. At a rough estimate, well over a million words will be spoken in the Sections. It is said that the human mind can form no clear idea of a million, except by way of comparison. Senor Ibanez, the Spanish novelist, has recently written in three weeks a novel containing 80,000 words; this is regarded as a *tour de force*; he would have to repeat it thirteen times, would have to write thirteen fat volumes, to produce a million words. That number of words would fill over 600 pages of the BRITISH MEDICAL JOURNAL. The Association undertakes that a report of the proceedings of the Sections shall be published, and has made certain rules for the conduct of Sections the observance of which helps to ensure not only satisfactory sessions but interesting published reports.

On this, as on previous occasions, the BRITISH MEDICAL JOURNAL will have a reporter in each Section, but even so the collection, preparation, printing, and publishing of reports of forty sessions is a big task. In this connexion is it out of place to say that the members of the British Medical Association who are unable to be present have the right to expect readable reports eliminating mere prolixities but retaining all matters of interest? Experience long ago showed that the haphazard acceptance of a number of papers on subjects having no relation to each other did not usually result in fruitful debates, and the policy of asking the officers of Sections to arrange a discussion for each session was adopted. It has proved successful; it has stimulated interest, attracted good audiences, and has usually led to interesting and informative debates. The officers of the Section—its president, vice-presidents, and honorary secretaries—select a subject and invite someone who has given special attention to it to produce a short review, summarizing existing knowledge and indicating points upon which opinion is not settled. The rule was made that these opening remarks should not contain more than 5,000 words (a little over three pages of the JOURNAL), and later on it was decided to put the opening papers into print a month or two before the meeting and to supply copies to members who wished to take part in the debate; at the same time the opening speaker was informed that his audience might be assumed to have studied his paper, and that, instead of reading it all out, he should confine himself to indicating the heads to which subsequent speakers might most profitably direct their remarks.

It was believed that in this way freedom and spontaneity would be encouraged and time afforded for a larger number to take part in the debate. On the whole the plan has worked well, but certain difficulties have been encountered. Opening speakers have not always been willing to pick out heads for discussion without giving reasons for their choice and indicating their own opinion; in some instances this turns out to be tantamount to reading out the whole or nearly the whole of what is already in print, and the chairman may not consider it advisable to interfere, for he may feel that if the

opening is too condensed it will not be easy to get the discussion going. Another difficulty arises when the officers consider that the subject has several aspects which should be introduced by as many separate speakers; examples will be found in the programme of some of the Sections this year. The judgement of the officers is not questioned, but one effect is that when there are three or four openers and each produces a paper 5,000 words long, some 15,000 or 20,000 words may have to be printed in advance, and when eventually published will fill ten to fifteen pages of the JOURNAL. If there are several opening speakers and they do not read out their remarks in full the time of the Section is saved, but the volume of matter coming in to be printed is apt to be increased. The regulation with regard to independent papers is that they shall not exceed a quarter of an hour in delivery, and that the text submitted for publication shall be what is actually read and not an expansion thereof. It is provided also that no subsequent speaker shall occupy more than seven minutes. The latter rule is generally observed, but the former is often violated.

The Association has made special arrangements to add a number of pages to issues of the BRITISH MEDICAL JOURNAL during the autumn to provide for the speedy publication of reports of the work of the Sections. With these additional pages the total number of pages available is about 400, and a very simple arithmetical calculation will show that if there are forty sessions this means an average of ten pages for each session. The following resolution, adopted unanimously by the Council of the Association, is published for general information:

That the attention of Officers of Sections and contributors to those proceedings be drawn to the fact that the Council provides an addition to the number of pages in the JOURNAL during the autumn for the publication of the proceedings of the Sections of the Annual Meeting, and that such provision cannot be exceeded.

BIRTHDAY HONOURS.

THE list of honours conferred on the occasion of the King's birthday includes a baronetcy to Sir Berkeley Moynihan. It is unnecessary, and, indeed, would be an impertinence, to attempt to set out here the great services he has rendered to surgery, and the high reputation he has achieved not only in this country but throughout the world, especially in America. He is a member of the Council of the Royal College of Surgeons of England, a Fellow of the American College of Surgeons, and Professor of Clinical Surgery in the University of Leeds as well as surgeon to the Leeds Infirmary. He delivered the address in surgery at the annual meeting of the British Medical Association in Brighton in 1913. Memories, however, are so short that we may properly recall the fact that he served continuously throughout the war, attained the rank of Temporary Major-General, and was a member of the Army Medical Advisory Board. In connexion with these services he received the C.B. in 1917, and the K.C.M.G. in 1918. He had received the honour of knighthood in 1912. By conferring a knighthood upon Professor W. M. Bayliss, F.R.S., the Crown has recognized one of the leading physiologists in this country, whose reputation as a philosophical physiologist is known throughout the world. His most important contributions have been in connexion with the vasomotor nervous system, secretion, the physical chemistry of enzyme action, and the properties of colloidal systems. During the war his researches, especially with regard to traumatic shock, afforded a scientific basis for treatment which resulted in conspicuous benefit to the troops and the saving of many lives. Dr. Hugh Kerr Anderson, F.R.S., who receives the same honour, is a nephew of the late Dr. Elizabeth Garrett Anderson, and is now Master of Gonville and Caius College, Cambridge, in which capacity he showed graceful hospitality to members of the Association when it held its annual meeting in Cambridge in 1920. He is a member of the Cambridge

section of the Royal Commission on the Universities, and was at one time lecturer on physiology in the University of Cambridge. Dr. John Macpherson receives the honour of knighthood in recognition of his excellent services as Commissioner in Lunacy for Scotland since 1899, a post he has just vacated. He was for some years lecturer on mental diseases at the School of Medicine of the Royal College of Physicians and gained wide clinical experience while senior assistant physician to the Royal Asylum, Morning-side, and medical superintendent of the Stirling District Asylum. He has recently accepted, for a term of three years, the chair of psychiatry in the University of Sydney, in order to organize the teaching and practice of psychiatry in the University and develop the clinic for mental diseases already existing. The same honour is conferred upon Dr. A. J. Rice-Oxley, physician to H.R.H. Princess Beatrice, and now for a third time mayor of Kensington. During the war he was medical director and acting physician to the Princess Beatrice Hospital for Wounded Officers and to the Dorchester House Hospital for Wounded Officers, and received the C.B.E. in 1919. A knighthood is conferred upon Dr. David Maurice Serjeant, in connexion with his unique position as colonist, volunteer, patriotic writer, and municipal worker. Among the honours conferred upon officers of the Army and Navy is the K.C.B. to Surgeon Vice-Admiral Sir Robert Hill, K.C.M.G., Medical Director-General R.N. Sir Robert Hill during the war was principal medical officer of the Grand Fleet. The same honour is received by Major-General A. P. Blenkinsop, D.D.M.S. Eastern Command, who gave distinguished services during the war as Assistant Director-General A.M.S. and D.M.S. Mesopotamia. He saw service also in Sierra Leone in 1886-89 and in South Africa in 1900-2. The Hon. Maui Pomare, who receives the K.B.E. (Civil), is a member of the Executive Council of the Dominion of New Zealand, representing the native race, and has recently been Minister in Charge of the Cook Islands. He holds the degree of M.D. The King has conferred the K.C.V.O. upon Mr. Richard Robert Cruise, surgeon oculist extraordinary to the King and surgeon to the Westminster Ophthalmic Hospital. Surgeon Commander Frank Hinton Nimmo, R.N., is appointed a member of the fourth class of the Royal Victorian Order. The distinction of C.M.G. is conferred upon Dr. A. R. Cook, in recognition of his services to the Uganda Protectorate; upon Dr. Emilias Hopkinson, travelling commissioner in the Gambia Protectorate; and on Dr. A. E. Horn, director of medical and sanitary services in the Straits Settlements and Federated Malay States. The I.S.O. has been received by Major Lynsdale, acting professor of materia medica, Medical College, Madras, and the Kaisar-i-Hind medal by Mr. E. H. Hankin, D.Sc., late chemical examiner to the Government of the United Provinces; before and after his acceptance of that appointment in 1892 he made numerous valuable contributions to bacteriology, and has written also on the flight of birds and on Mohammedan art. The same distinction has been received by Miss Eleanore Thompson, lady superintendent, Medical College Hospital, Calcutta, and Miss Susan Campbell, L.R.C.P. and S., in charge of the Zenana Hospital, Scottish Missions, Rajpootana, and Dr. Edith Mary Brown, Principal, Women's Christian Medical College, Ludhiana, Punjab. Nor must we forget the Right Hon. Sir Auckland Geddes, K.C.B., British Ambassador at Washington, who receives the G.C.M.G., for he is a member of our profession, and was successively assistant professor of anatomy at Edinburgh and professor of that subject at the School of the Royal College of Surgeons in Dublin and in McGill University. We note also that the honour of knighthood is conferred upon two distinguished exponents of sciences related to medicine—Professor F. W. Keeble, F.R.S., who holds the Sherardian chair of botany at Oxford, and Dr. E. J. Russell, F.R.S., director of that great agricultural institution, the Rothamsted Experimental Station. Mr. Herbert Atkinson Barker, described as "specialist in manipulating surgery," is also made a knight.

THE CONDITIONS IN POTTERS' SHOPS.

An exhaustive inquiry into the atmospheric conditions in potters' shops has been made by Dr. H. M. Vernon and Mr. T. Bedford, and an account of their investigations has just been issued by the Industrial Fatigue Research Board as Report No. 18. In these shops the potters make plates, cups, saucers, and other articles from moist clay or from china "slip," and the articles are transferred at once to the drying stores, which are usually situated in the middle of the shops. The stores, which are heated by steam pipes, pour large volumes of hot air into the shops, which in consequence are considerably overheated. Systematic observations, made both in summer and winter, showed that the majority of the potters' shops were 5° to 9°F. warmer than engineering shops and boot and shoe shops, where work of a similar degree of activity is carried on. This means that through the greater part of the year the shop temperature was over 70°. This high temperature was not compensated for by increased ventilation, for the kata-thermometer observations showed that the average velocity of the air currents was only about half as great as that observed in boot and shoe shops (namely, 19 ft. a minute, as against 36 ft.). Apparently the potters themselves did not experience much discomfort from the adverse conditions, as they opened very few of the shop windows until the temperature rose above 70°, and even when it was over 80° they opened only two-thirds of them. The reason is that they had got acclimatized to the heat, as they usually start work in the industry at the age of 14. Nevertheless, there can be little doubt that it is bad for their health. In the second half of the report Dr. Vernon describes a long series of investigations on the efficiency of the various types of potters' stove, and comes to the conclusion that almost all of them are badly constructed. The very few well-constructed stoves met with allowed hardly any hot air to pass back into the shops, and were therefore much more efficient from the mechanical point of view than the rest, as well as conducing to human efficiency. It is curious that in such an important industry as that of pottery so little definite information was available on certain fundamental principles. The pottery manufacturers were not at all agreed as to whether, in the drying of their ware, it was desirable to have a fairly rapid current of moderately warm air, or as an alternative a slow current of hot air. The report goes somewhat fully into the question, and shows that the second alternative is the correct one, and it suggests alterations in the form of the drying stores by means of which it can be achieved.

THE SPAS OF FRANCE.

The battle of the spas has been joined. The principal British spas have formed themselves into a federation, the better to make known to the medical profession and the public their therapeutic merits and social amenities; and they have issued an attractive publication, *British Spas and Health Resorts*.¹ These are most commendable measures, for undoubtedly the merits of British spas are not sufficiently known even to the medical profession of this country. Inquiries are beginning to be heard about the spas in Germany and German-speaking countries; they had an astonishing vogue before the war, and it should be noted that some of the most popular of them are not within the boundaries of the German Reich; Marienbad and Karlsbad are examples. France is also seeking to make its spas better known. Some time ago the French Minister of Public Works constituted a special department in Paris called the Office Français de Tourisme, with branches in Great Britain, in the United States, Spain, and Switzerland. One of the first acts of this department has been to publish a small album entitled *The Spas of France*, copies of which can, we understand, be obtained from the office in Great Britain (56, Haymarket, London, S.W.1). The volume is beautifully illustrated

¹ *British Spas and Health Resorts*. The Official Publication of the Federation of British Spas. Cheltenham and London: E. J. Parry and Co., Ltd.

by excellent photographs of all the principal spas; the particulars given are very businesslike, and include notes on the climate, on the sanitary administration of the place, on its springs and bathing establishments, on the chemical composition of the waters, and on the clinical indications for their use; contraindications are also wisely enumerated. The translation into English has been well done. The majority of the places mentioned are little known in this country; everybody has heard of Aix-les-Bains, Vichy, Vittel, Contrexéville and Plombières, but beyond these spas knowledge is fragmentary; it will be a surprise to many to find that the album contains particulars of 83 spas, ranging from the Vosges to the Pyrenees. Probably not everybody knew that Dax, in the Landes, the level country north of the Pyrenees, possesses mud baths, which are considered to be useful in the same classes of cases as those in which the Bohemian mud baths are employed. The mud at Dax, which has an oily consistency, contains a mineral element derived from the alluvial mud of the river Adour, and a vegetable element yielding a rich cryptogamic flora. It also displays natural radio-activity. The amount of space given to each spa is roughly proportional to the merits of the spa and the excellence of its bath houses and installation generally; thus four pages are given to the chief spas, two to those the management of which is less perfect, and one or less to small spas possessing active waters but somewhat insufficient means for their therapeutic application. Before the war an energetic campaign had been undertaken to improve those French spas which stood in need of it; in particular, attention was, at the request of the Académie de Médecine, given to the general sanitation of each town and the purity of its ordinary water supply, as well as to the canalization of the mineral water to prevent contamination. This campaign has been vigorously resumed and great improvements have already been carried out. One very distinct advantage of many of the French spas, which in this respect compare favourably with most of those in German-speaking countries, is that they are situated in beautiful regions where the hale members of families visiting the spas may find distraction other than tennis and golf; these also are provided.

CLOPTON HAVERS.

ALTHOUGH the Haversian canals are familiar to every student, the name and works of their describer, Clopton Havers, are little known to this generation; it may, however, be mentioned that No. xlii of the unsigned *Archaeologica Medica*, which were contributed to our pages by our lamented colleague, C. Lonis Taylor, was devoted to Havers, "an early English histologist" (BRITISH MEDICAL JOURNAL, 1898, i, p. 224). Dr. C. B. Reed¹ of Chicago has therefore performed a service to us in providing an illustrated account of this forgotten anatomist's work. He has not been able to add much to the biographical details given in Munk's *Roll of the Royal College of Physicians* and J. F. Payne's life of Havers in the *Dictionary of National Biography*, but he mentions that Havers was the son of a clergyman, and was largely indebted for his education to Dr. Richard Morton, fellow and chaplain of New College, Oxford, who later transferred his activities to medicine, and, as a friend of Thomas Sydenham, may have introduced his pupil to "the English Hippocrates." In this connexion it is interesting to recall the tradition that Havers and another composed, or at least put into good Latin, Sydenham's *Observationes Medicae*. Born between 1650 and 1660, Havers was at St. Catherine's Hall for a time, but left Cambridge without a medical degree, which he obtained on July 3rd, 1685, at Utrecht, with an inaugural dissertation *De Respiratione*, translated four years later in the *Philosophical Transactions* of the Royal Society of London. He then started on the physio line in London, specializing in anatomy, and on December 15th, 1686, was elected a Fellow of the Royal

Society. Not unnaturally it was to this body that he communicated in 1689, 1690, and 1691, the first descriptions of the minute structure of bone, and the earliest definite account of the bony canals that keep his name in remembrance. The papers were published in a collected form in 1691 as "Osteologia Nova, or some new Observations of the Bones and the parts belonging to them, with the manner of their accretion and nutrition," in English in London, and in Latin at Frankfurt the next year, at Amsterdam in 1731, and at Leyden in 1734. The original English edition, which was the standard source of reference for more than forty years, is now extremely rare; indeed, it appears that there are only four copies in America. It contains a description of the periosteal prolongations, afterwards known as Sharpey's fibres, which were regarded as nervous, and not, as was later shown, merely as connective tissue; an account was also given of the folds in the synovial membranes, which were spoken of as mucilaginous glands. Dr. Reed briefly sketches the contemporary conditions in the medical and scientific world, out of which Havers so conspicuously emerged, and remarks that there is probably nothing in English literature so nearly representing the restless, searching currents of thought during the late seventeenth century as his *Osteologia*, which, though containing numerous postulates and ill-founded assertions, offers many gems of careful reasoning and attentive observation. Havers's career was prematurely cut short by a malignant fever on April 29th, 1702, at Willingdale Doe in Essex.

THE ETIOLOGY OF TYPHUS FEVER.

DURING the last decade many investigations have been carried out in regard to the etiology of typhus fever, and quite a number of different organisms have been asserted to be the infective agent. In the JOURNAL of May 27th, 1922 (p. 849), there was published a note on a communication made to the Moscow Medical Society last April by Dr. N. Kritch in which an anaerobic micrococcus, described as the *Microbion typhi exanthematici*, was suggested as the cause of typhus fever. Four requisites have been laid down as determining experimental typhus fever: (a) Induction of the typical disease through inoculation from animal to animal indefinitely; (b) presence of the characteristic vascular lesions, especially in the brain; (c) absence of secondary infections with ordinary bacteria; and (d) development in recovered animals of immunity to subsequent injections of typhus virus. At most only one of those four requirements, so far as is known, has been complied with in the experiments of Dr. Kritch. Certain proofs of etiological relationship to typhus fever were previously made in regard to the *Rickettsia prowazeki* of da Rocha-Lima (*Arch. f. Schiffs- u. Tropen-Hyg.*, 1916, xx, 17), and the *B. typhi exanthematici* of Plotz (*Journ. Amer. Med. Assoc.*, 1914, lxii, 1556), but Olitsky, working in the laboratories of the Rockefeller Institute for Research, arrived at the conclusion that neither of those organisms could be regarded definitely as the inciting agent of typhus, although he had been inclined for some years to accept the etiological relationship of the Plotz bacillus owing to the fact that he had found specific antibodies against the organism in the blood of typhus patients, that with it, it was believed, experimental typhus in guinea-pigs had been induced, and that a similar bacterium was recovered from typhus-infected lice. In the *Journal of Experimental Medicine* (1921, vol. xxxiv, p. 525) Olitsky published an article, summarizing the results of his investigations into the etiology of typhus fever, which has an important bearing not only upon the organisms which he discusses there, but also upon that now reported by Dr. Kritch. The investigations reported in this paper relate to the bacteria which could be cultivated from the blood and spleen of guinea-pigs at different stages of infection with the virus of typhus fever. The findings indicate that the virus of typhus fever is distinct from ordinary bacteria, and, as the disease set up by the virus progresses, the infected guinea-pigs become subject to secondary or concurrent invasion by bacteria, a mixed

¹ C. B. Reed, *Bull. Soc. Med. History of Chicago*, 1922, ii, 371-388.

infection being induced. The bacteria which under the influence of the typhus virus invade the body of a guinea-pig are, Olitsky states, of several kinds, and vary not only among themselves, but also with the day of the fever on which the examination is made. Since the more unusual of these organisms (the *Platz bacillus*, an anaerobic streptococcus, an aerobic diphtheroid, and a diplobacillus) are non-pathogenic for guinea-pigs, while the more common bacteria (such as a Gaertner-type bacillus, Welch's bacillus, the *proteus* bacillus, and the staphylococci) induce distinctive effects, and since all the bacteria could be suppressed without their reappearance in guinea-pigs inoculated with the virus containing them, Olitsky concludes that they are independent and unrelated to the true virus of typhus fever. Since, then, the body of the guinea-pig reacting to the virus of typhus fever appears to be readily invaded by a variety of bacteria whose presence complicates the typhus infection, but which have no etiological relation to the specific disease, the report made by Dr. Kitch, equally with previous reports, must, as we pointed out in noticing her research a fortnight ago, be received with reserve.

PLANT DISEASES.

BEFORE the discovery of the tubercle bacillus or the cholera vibrio extensive studies had been carried out on the bacterial diseases of plants, though the science of plant bacteriology did not progress with the same rapidity as the study of human bacterial diseases, probably because it did not make so strong an appeal to the imagination of research workers. But the work of recent years has revealed the fact that plants are the victims of bacterial diseases and undergo pathological processes remarkably similar to those occurring in human beings. Infection is often carried by insects or occurs through a wound of the root; there is a stage of bacterial invasion resulting in either local or generalized lesions; the bacteria produce disease by mechanical interference with function and by the secretion of toxins. Such diseases as pear blight, the bacteriosis of beans, crown gall and black rot of cabbage—to mention only a few—are well-defined bacteriological infections in which the morbid processes are as well understood as in any bacterial disease of man. Many of these diseases can be reproduced experimentally by inoculation with laboratory cultures of the causal organisms. Of the protection which some plants enjoy or the reason of the susceptibility of others to these bacterial invaders little is known; although the somewhat fantastic claim has been made, we do not say with what justice, that anaphylaxis may be induced in onions. A most readable little book, *Les Maladies Parasitaires des Plantes*, by M. Nicolle and J. Magron, is written from the medical point of view, and deals with diseases of plants caused by insects, worms, and fungi, as well as bacteria. There is very little in it directly concerned with human disease, but no medical man could read it without enjoying a wider outlook on pathology through the consideration of the constant menace parasites threaten towards man and plants alike.

THE next of the exchange lectures with Dutch universities, arranged by the University of London, will be given on Monday next, June 12th, by Dr. Mark Jansen, lecturer on orthopaedics in the University of Leyden. The subject of the lecture is "Injurious agents and growths." Professor G. Elliot Smith, F.R.S., will take the chair at 5 p.m.; admission is free without ticket. A reception will be held at 4.30 p.m. Dr. Jansen in 1918 had arranged, in conference with Sir Robert Jones, to undertake the treatment of orthopaedic cases among the British soldiers and sailors interned in Holland. The scheme, we believe, was never carried out, as it had not been completed at the time of the armistice, but this country is none the less indebted to Dr. Jansen for his ready consent to help.

Scotland.

EDINBURGH UNIVERSITY EXTENSIONS.

ON June 2nd there was opened the new University of Edinburgh, which contains 100 lecture rooms, at the new King's Buildings, situated several miles from the city. Principal Sir Alfred Ewing, in declaring the building open, said that it was barely two years since the foundation stone of the chemical laboratories had been laid by the King, and, almost without observation, the laboratories had not only come into existence, but into active utilization. They had to recognize that not only chemistry but other departments also required new quarters, and they looked forward to a succession of scientific departments coming out to join chemistry at Liberton. It became obviously desirable, if not imperatively necessary, to provide some amenities for the members of the university who were taken away from the social comforts of the unions and the various restaurants, and the University Court had, with the co-operation of the University Union, been able to provide this new accommodation, which was a novel experiment on the part of the Union.

EDINBURGH SICK CHILDREN'S HOSPITAL.

The annual meeting of the supporters of the Royal Edinburgh Hospital for Sick Children was held on June 2nd, with Sir John R. Findlay in the chair. The chairman said that the most agreeable feature of the annual report was that for the first time since the war a slight decrease in expenditure was shown. They might congratulate themselves that they had at last turned the corner, though they could never hope to approach pre-war expenditure. During the whole period of the war, however, they had been singularly fortunate in the amount they had received in legacies; and the position was that at the end of that trying time they had succeeded in paying their way and had larger funds than they possessed at the outset. An institution like that hospital, however, could not afford to remain still, and every improvement made in the way of communication brought more patients to their doors, while another cause of the increased expenditure was the increased cost of a great many modern methods of treatment. The constitution of the hospital laid it down that it was for the use of the poor, but this was a relative term, and for their purpose the poor meant those who were unable to pay for such treatment as the necessities of their case demanded. The system of fixed charges for treatment was entirely at variance, in his opinion, with the principle of a voluntary hospital, and they could not exploit the services of the surgeons and physicians who gratuitously placed their skill at the disposal of the public.

SOUTHFIELD TUBERCULOSIS COLONY.

A new institution for the treatment of tuberculosis, on the colony principle, has been opened at Southfield, near Edinburgh, under the auspices of the Royal Victoria Tuberculosis Trust. This institution is to serve an important function in connexion with the training of medical students in tuberculosis, and, under the direction of Sir Robert Philip, will be a notable addition to the teaching equipment of the Edinburgh Medical School. The colony accommodates, at present, thirty-six patients, and is intended for experimental work and the investigation of special cases. Cases will be accepted which, because of the time required for cure or their obscure nature, could not be dealt with adequately at the ordinary sanatorium, and there will be no limit to the period during which patients may remain. It is intended that the natural history of tuberculosis in its rarer varieties and manifestations shall be studied at Southfield through the special cases brought to the institution, and the new remedies or methods, which are announced from time to time, will be tested there. A feature will be made of the clinical records in the institution: operations are to be photographed and colour drawings made of any special conditions. The colony was opened on May 31st by the Duke of Sutherland, Lord High Commissioner, when Sir Ralph Anstruther, President of the Royal Victoria Trust, and Professor Harvey Littlejohn, also spoke.

GARSCUBE COTTAGE HOSPITAL, GLASGOW.

Garscube Cottage Hospital, on the outskirts of Glasgow, entered on June 1st upon a new phase of its existence, when it was opened as a rest home for mothers and babies in

¹ *Les Maladies Parasitaires des Plantes*. Par M. Nicolle et J. Magron. Paris: Masson et Cie. 1922. (Cr. 8vo, pp. 359. Fr. 8 net.)

connexion with Glasgow Maternity Hospital. This cottage hospital was opened in 1876; and carried on the work for which it was originally intended until about 1900. During the war it was used by the Red Cross Society as an auxiliary hospital, and after the signing of the armistice until last August the Ministry of Pensions made use of its facilities.

England and Wales.

POST-GRADUATE COURSES AT NEWCASTLE-UPON-TYNE.

UNDER the direction of a committee representing the Council of the University of Durham College of Medicine, the honorary staff of the Royal Victoria Infirmary, and the North of England Branch of the British Medical Association, a special clinical post-graduate course will be held in the Royal Victoria Infirmary, Newcastle-upon-Tyne, from July 3rd to 15th inclusive. The intention is to enable practitioners to undertake a fortnight's intensive study in the wards and out-patient departments; the mornings will be devoted to clinical medicine, surgery, gynaecology, and pathology, while in the afternoon classes will be held in venereal diseases, medical diseases of the eye, and in the examination of the blood and diseases of the blood. The fee for the whole course is 10 guineas, for the morning course only 6 guineas, and for the afternoon course only 6 guineas. Applications to attend the course should be sent not later than June 20th to Mr. Norman Hodgson, M.B., B.S., 14, Jesmond Road, Newcastle-upon-Tyne, from whom a detailed syllabus can be obtained.

LIVERPOOL EYE AND EAR INFIRMARY.

The annual meeting of this hospital furnished a striking exception in the cheerful and encouraging note of its report to those of other institutions in the city, as far as finance was concerned. The annual report showed a credit balance of over £650 during the past year. Some little time ago the question of closing some of the wards was mooted. Fortunately the committee decided to take payment from patients who after careful and sympathetic investigation were found to be in a position to make some payment towards the cost of maintenance while treated at the hospital. The result proved satisfactory; almost in every case the patient preferred to make some payment than be beholden altogether to charity. More accommodation was required, especially for cases of diseases of the ear, as well as for the nursing and service staff. It was also contemplated to provide a private ward for paying patients who would defray the cost of their maintenance and pay the medical staff according to private arrangement. Such improvements could not be undertaken without the assistance of the charitable public. The chairman emphasized the fact that the benefits of treatment as far as the poor were concerned would, so far from being jeopardized by the voluntary system of payment by patients, be enhanced through efficiency all round, and thus sustain the reputation of the hospital now enjoyed for over 100 years.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

Mr. H. C. Wardleworth Nuttall has been appointed honorary assistant surgeon to the Royal Southern Hospital, Liverpool. He studied medicine at the University of Liverpool, where he gained several honours and took the diplomas of M.R.C.S., L.R.C.P. in 1910. During the war he was lieutenant R.N.V.R., and served in the Mediterranean and German S.W. Africa. Later he acted as deputy medical transport officer in Scotland, and had the supervision of naval patients in Edinburgh. Mr. Nuttall became F.R.C.S. Edin. in 1920, and in 1921 obtained the F.R.C.S. Eng. He is surgical tutor and pathologist at the Royal Southern Hospital and honorary surgeon to the Bootle Borough Hospital.

POST-GRADUATE COURSE IN DISEASES OF CHILDREN.

The syllabus of the post-graduate course in diseases of children, already announced by the Fellowship of Medicine and Post-Graduate Medical Association, is available and copies will be forwarded on application to the Secretary to the Fellowship at 1, Wimpole Street, London, W.1. The class lasts one week, during which clinical lectures and demonstrations will be given by members of the staffs of the East London Hospital for Children (July 3rd), Paddington Green Children's Hospital (July 4th), Victoria Hospital for Children (July 5th), Queen's Hospital for Children (July 6th), and St. Marylebone General Dispensary (July 7th).

Correspondence.

FIRST REPORT OF THE MINERS' NYSTAGMUS COMMITTEE.

SIR,—Those who have had practical experience of the disease will be as dissatisfied as I am with the general tenor of the first report of the Miners' Nystagmus Committee. The evidence given for their decisions is extraordinarily inconclusive.

It is the fashion for the moment to attribute the disease wholly to the deficiency of light. How, then, do they account for Snell's case of the disease in a ceiling paperer? I have had one or two cases where there was no deficiency of light. Such cases are simply not mentioned.

On page 29 we are told that "there does not appear to be any definite connexion between the thickness of the seams and the incidence rate." In support of this statement, which is in direct opposition to Snell's painstaking work on the subject, the committee gives Table VII, "Showing Thickness of Seam in which 1,613 Coal-face Men Worked." However, on looking at the table we find that the number of cases of nystagmus is 1,613, and that only one case of nystagmus occurred where the thickness of the seam was less than 2 ft., while 650 cases were found in those working where the thickness of seam was 6 ft. and over. Such a table is absolutely useless unless the number of men employed at each thickness of seam is stated. Obviously more men are employed in the thick seams than in those less than 2 ft. There might be only two men employed in the seam less than 2 ft., and 40,000 in the seams 6 ft. and over.

On page 40 there is a very curious example of the committee's reasoning:

"If lights amounting to 100 candle power are placed in a room having walls, floor, and ceiling of a reflecting power of 80 per cent., one-fifth of the light will be absorbed and four-fifths reflected."

Certainly.

"This reflected light is for all intents and purposes a new light of 80 candle power. The total effective light in the room is therefore the same as if the walls and ceiling had been black, and 400 lamps of 1 candle power each had been spread evenly over the walls, in addition to the original 100 candle power."

But it is to the amazing ignorance of first physiological principles that I wish to call attention. The minor ears not in the least for the total effective light in the pit; what he does care about is the light on the coal-face that he is hewing. Everyone knows that in a fairly dark room contrast of illumination is of supreme importance; one will see an object illuminated by a 1/2 foot candle when the rest of the room is lighted by a 1/10 foot candle far better than if the whole room had an illumination of a 1/2 foot candle.

I might criticize other points, but finding fault is always an invidious task. My object is only to urge the Committee to take more care in drawing up their second report, so that it may be throughout of scientific value.—I am, etc.,

Newcastle-upon-Tyne, June 1st. ARCHD. STANLEY PERCIVAL.

SIMPLE GOITRE.

SIR,—Lieut. Colonel McCarrison's article (April 22nd, 1922, p. 636) again strongly suggests the septic or toxic origin of goitre.

It may prove of interest in this connexion to call attention to the powerful action of iodine, as evidenced by its clinical use. Recently Dr. Louie Stegman, of Battle Creek, Michigan, published the report of a case treated with hypodermic injections of iodine, in which an increase of 40 per cent. in leucocytosis was demonstrated, the blood examination being made after the fourth weekly dose. I had previously failed to get an expected similar result, but my examinations were made after the first dose.

The case quoted above is important, as it practically establishes the action of iodine on a rational basis and obviates the necessity of classing it as a purely empirical effect as previously. There is abundant clinical evidence to support the view given above, and one can easily understand that iodine must have a powerful effect not only in cases of goitre, but in any condition in which the production of leucocytosis may be expected to be of effect. As I stated before the International Congress of Ophthalmology at Washington recently, "one

cannot expect to accomplish everything by an increased leucocytosis, but it is surprising what can be done."

One point more is also of interest. In two of my cases I have had to discontinue the use of iodine because symptoms of exophthalmic goitre supervened.—I am, etc.,

Montreal, May 9th.

RICHARD KING.

THE LYMPHOID DIATHESIS.

SIR.—General Burnham's observations in Albania (May 13th, p. 781) regarding the absence of appendicitis, enlarged tonsils, and adenoids in 20,000 cases observed, negatively corroborates my own observations extending over many years. These may be summed up as follows: Enlarged tonsils, adenoids, and appendicitis are diseases of one family, probably caused by the same or closely allied germs. They are diseases affecting the lymphoid tissue; and if a patient has adenoids when a child he is liable to disease of the tonsil and appendix when he grows up. Also, in this connexion he has the danger of tuberculous disease to face, either of the glands when young or the lungs when he reaches maturity.

The pupils in these cases are enlarged. Sir Wm. Jenner drew attention to the large pupil in patients suffering from enteric fever in contrast to the small pupil in cases of typhus. But I believe the large pupil in enteric fever will be found after the fever has disappeared. Those in charge of fever hospitals might kindly settle this point.

Enteric fever attacks the lymphoid tissue of the bowel, and the patients who are prone to tonsil trouble and appendicitis are more susceptible to enteric fever than their neighbours. For want of a better name these patients might be classed as having the lymphoid diathesis. When these "lymphoid" patients contract malignant disease it takes the form of sarcoma. They are practically immune to carcinoma. Here it may be observed that malignant disease of the spleen (a lymphoid organ) is very rare, in this respect contrasting sharply with the liver, an organ very prone to cancer growth.

For the prevention and treatment of those diseases of the lymphoid tissues I beg to refer to the treatment of phthisis of the lungs in Graves's *Clinical Medicine*, the last edition of which was published over fifty years ago.—I am, etc.,

Glasgow, May 13th.

JOHN T. MACLACHLAN, M.D.

ETIOLOGY AND TREATMENT OF DIABETES.

SIR.—To Dr. Barnes we have no further reply: we fail to see any connexion between his remarks and the question under discussion. Until the products of the biological activities of tapeworms have been isolated and compared with the abnormal toxic products of a tuberculosis patient, no comparison of this problem with our work is possible.

Dr. Cammidge states that he has not had the opportunity of seeing *in vitro* the results of fermentation of pure cultures of *B. amyloclasticus*. His further statement, therefore, that "certain of these alterations are found in all cases of typical diabetes, and probably explain why a particular type of organism should be a constant feature," is of no real value, since he admits that he has had no experience with this.

... allow any importance to his

... he has "carried out extensive bacteriological examinations of the faeces in diabetes." We are surprised that he has failed to find this organism, which is quite distinctive. It is well known that unlimited search for an organism may be made, but if the media and conditions of growth are not adapted to that organism no amount of labour will bring that organism to the front. Had Dr. Cammidge in his bacteriological work departed from stereotyped methods and used those methods we have indicated, we do not believe that he could have abandoned the work when he had satisfied himself "that variations from normal could be explained along the line of digestive disturbance."

What these digestive disturbances were and how the intestinal contents varied we asked Dr. Cammidge to explain before fully answering some of the points he raised. Dr. Cammidge gave us no definite reply to the question; we suppose, however, that he is referring primarily to the pancreatic secretion. We presume that it has not occurred to him that the high acidity produced by this organism might have been responsible for a prolonged stimulation of pancreatic secretion, which should have induced that definite chemical alteration in the intestinal contents to which he refers.

For Dr. Cammidge's work we have great admiration, but we believe that it is he who has put the cart before the horse,

and that had be used for a prolonged period of time the methods we have indicated he would not have abandoned a combination of bacteriological and chemical methods for the futilities of pancreatic insufficiency.

We stated explicitly in our paper that if the reaction of a fermenting mash is taken the acidity is found to rise rapidly. Other observers working with a similar acetone-producing organism have found that a high acidity precedes the formation of acetone. This production of acidity would reflexly stimulate the pancreas in an attempt to neutralize it, and this, combined with any possible occasional extension of the acidity up the pancreatic duct, would result in the interstitial fibrosis of the pancreas mentioned by so many observers. We believe, however, that the rôle of the pancreas in diabetes is purely secondary. Labbé, Professor of Pathology at the Faculty of Medicine, Paris, in his admirable monograph on diabetes mellitus (1922), discusses very fully the rôle of the pancreas in diabetes. His findings essentially are that a certain amount of fibrosis of the pancreas is present in diabetes—sometimes a considerable amount—but that it is not always present; that it may occur *post mortem* in non-diabetic cases; and that its magnitude bears no relation to the severity of the diabetes. He concludes his chapter on the pancreas by stating: "Anatomically and physiologically we have not yet been able to localize the functional disturbance, which clinically manifests itself by an imperfection of the carbohydrate metabolism."

We have demonstrated an organism which acting by a diastatic ferment can produce all the abnormal products met with in diabetes. Since the paper appeared we have ascertained that the organism producing this ferment can also split up glycogen. Can Dr. Cammidge mention any other body ferment which can produce these abnormal products and also break down glycogen? Our findings are so clear and definite, and can be repeated so easily by any bacteriologist who will trouble to follow our method in detail, that there can be no doubt that the evidence was sufficient to publish our results. We would point out that our statements are all based on absolute experimental findings.

Dr. Cammidge in his first letter referred to the disappearance of acetone on giving carbohydrates. The mere sipping up of the culture tubes with more carbohydrate when fermentation with *B. amyloclasticus* had commenced would not necessarily allow further growth to proceed. The organism is extremely variable, and in the case of a similar organism used during the war similar difficulties appeared; great as these difficulties were, however, it did not prevent something like 5,000 tons of acetone being produced by its action.

Quite apart from the consideration of the primary fermentation in the intestines, however, is the question of the secondary action produced by the diastatic ferment when absorbed by the liver and tissues, and the action upon the liver cells of the acetone and N butyl alcohol also produced. These combined with the effects of organic acids directly and indirectly upon the pancreas give a rough general idea of the working of this organism present in the intestines of diabetics.—We are, etc.,

ARNOLD RENSHAW, M.D.

THOMAS H. FAIRBROTHER, M.Sc.

Manchester, May 31st.

PREPARATION OF VACCINE LYMPH.

SIR.—May I be allowed to make some comment on your editorial article on the subject of the preparation of calf lymph appearing on page 847 of your issue of May 27th, which has special reference to my publication on the subject which appeared in the recent issue of the *Journal of Pathology*? I do so with the desire to help those of your readers who, from various points of view, are likely to be interested in the subject, and who, I think, might appreciate a knowledge of the circumstances which led me to make my investigation.

It will be seen from the following that there was a serious shortage in the supply of calf lymph in Great Britain during the Scottish small-pox epidemic of 1920. The second annual report of the Scottish Board of Health for 1920, published last year, reveals the situation with regard to the adequacy and source of supplies of calf lymph, as they existed in Great Britain two years ago, in the following passages (pp. 51-54):

"To this total of 545,000 (that is, persons vaccinated at the public expense) there must be added another 200,000, either done privately or at the public expense, in areas from which no returns are available, making a total of, approximately, 750,000 for the whole of

Scotland. The seriousness of the situation was early recognized. . . . The desirability of a widespread vaccination movement and the need for an adequate supply of calf lymph then engaged our attention. Arrangements were made with the Government Lymph Establishment and (as the margin available for use in Scotland without unduly encroaching on the English reserve supply soon proved insufficient to meet the needs of Scotland) with approved private firms for the supply of calf lymph for the whole of Scotland.

"During the year, since the beginning of the outbreak, 845,711 nominal doses were distributed. . . . The majority of the local authorities in Scotland offered free vaccination to the inhabitants, and in addition a considerable number of vaccinations were carried out by practitioners who obtained their lymph from private sources. It was ascertained that the sales through wholesale houses and retailers attained unprecedented proportions. As the preparation, elimination of extraneous organisms, microscopic and bacteriological examination of lymph necessarily involve time, the approved and available stocks in Great Britain were inadequate to meet the demands, and the continuity of the supply was secured only by calling on French reserves. . . . The reports obtained from the medical officers of health, and confirmed in a number of areas by examination by our medical officers of very considerable numbers of cases, show that the various strains of lymph secured a very high percentage of successful vaccinations. The strains, while active and in a small percentage of cases giving severe reactions, did not in any authenticated case result in any ultimately serious consequences." (*Italics are my own.*)

About one half of the total quantity of lymph required was supplied by an approved private firm of whose laboratory at that time I was director: the research to which your editorial article refers was made in this connexion. Much of the valuable information which you desire to see placed before your readers (for example, the number of cases for which the lymphs in question were used and the results showing personal and insertion success), I regret to say, has not been made available. But this much I think your readers will regard as significant—namely, that the approved private firm of whose laboratory I was in charge continued to supply calf lymph during 1921 to the Scottish Board of Health. This contract for further supplies was again renewed at the beginning of 1922.

It was unfortunate that no opportunity was afforded during the Scottish small-pox epidemic of 1920 to watch the comparative results of lymphs treated by the methods I describe, and particularly those prepared and kept in cold storage at the Government Lymph Establishment at Hendon, which at that critical period was not in a position to furnish the material so urgently needed. Your readers will be able to realize from these circumstances that my attention was necessarily turned to devising a precise method for the rapid preparation of bacteria-free lymph on a large scale.

The question of subsequent storage of a purified lymph in order to avoid the risk of loss of potency is another matter. Whether storage takes place at 45° to 55° F., as I favour, or at 10° F., as occurs at the Government Lymph Establishment, must depend upon the period and temperature of exposure of the lymph from such time as it leaves the manufacturing laboratory to the time when it becomes inserted upon the patient's arm.

Whereas the Scottish Board of Health is accustomed to insert a clause in its contract with the approved private firm (above referred to) to the effect that the activity of the lymphs supplied must be guaranteed for a period of not less than six months after receipt, the Government Lymph Establishment enjoins that Government lymph supplied to public vaccinators in England and Wales shall not be used when it has been in the recipient's possession for a longer period than seven days, and, further, that such lymph as remains unused after the lapse of seven days following receipt should be at once returned to the Government establishment. The interpretation of these facts is that Government lymph is not to be relied upon for a longer period than seven days after issue from cold storage at 10° F., yet lymph prepared by the process I describe and stored subsequently at 45° to 55° F. can be relied upon to retain its activity for six months and has so proved itself.

I hardly like to admit that the sudden and inexplicable loss of potency in lymph, which I have not infrequently encountered, is altogether due to my lack of experience or unfamiliarity with the esoteric pathology of the "lymph expert," and I can only add that every private lymph manufacturer I have met is equally familiar with the phenomenon. In this connexion I may recall two occasions, one in Belgium in 1915 and the other in Italy in 1918, when whole batches of lymph supplied by the Government Lymph Establishment at Hendon for use in the field proved to be totally inert upon arrival. In the Belgian instance I counted 2,000 inert tubes in a single batch.

A point also has been made that the prevalence of foot-and-mouth disease in animals at a period of epidemic small-pox might gravely interfere with the rapid preparation of calf lymph in the manner I advocate. In the recent widespread epidemic of foot-and-mouth disease the total proportion of calves affected, including contacts, destroyed in Great Britain was, I understand, but a small fraction of 1 per cent. Seeing that the average yield of lymph per calf is not less than 15,000 doses (this figure being based on the yield obtained from the last 100 calves privately vaccinated), 70 calves might be expected to yield a million doses, and such difficulty as might arise—due to prohibition or limitation of movement of calves to an institutional laboratory—may be overcome, I suggest, by the employment of a mobile laboratory, simply and suitably equipped.

I would like to add that if my paper published in the *Journal of Pathology* appears somewhat abridged, it is rather because of the strict limitations and consideration for space imposed by the editors of that journal. I would mention, however, that your editorial article deals only with that portion of my paper which relates to lymph preparation, and that some of the points raised are answered, I think, in the later portions dealing with the subject of immunity and hypersensitiveness.

Vaccination is a thorny subject, and I greatly regret that it should be considered that my publication in the *Journal of Pathology* contains "animadversions (and they are not few) on lymph as others make it." I had no intention of so offending, and I am still unconscious of the reason for this criticism.—I am, etc.,

MYER COPLANS.

The Bacteriological Department, King's College,
University of London, June 2nd.

DETOXICATED VACCINES.

SIR,—In the *BRITISH MEDICAL JOURNAL* of May 27th, 1922, there appeared a criticism of my researches by Dr. C. E. Jenkins. Criticism is valuable as it stimulates further experiment. I have not so far criticized Dr. Jenkins's paper on "Residual vaccines," which appeared in the *BRITISH MEDICAL JOURNAL* of June 11th, 1921 (p. 846), so I would like this opportunity to make a few general remarks, not only with regard to his letter but also in relation to his paper published about a year ago.

Dr. Jenkins states in his paper that by using my old method in combination with treatment with hydrogen peroxide he removes *all* of the toxins from the germs. He states, moreover, that the endotoxins as well as the thermolabile toxins are destroyed by heating to 120° C. He finally autoclaves his vaccines at that temperature to sterilize them.

If, as he states, a temperature of 120° C. destroys the toxins, why does he bother to remove the toxins by the other process, since according to his statement they will be destroyed in any case by the final autoclaving? After stating that the toxins are destroyed by a temperature of 120° C. he goes on to explain that the toxicity of his residual vaccines prepared by this treatment is due to an inherent toxicity in the protoplasm of the germs themselves, and he appears to believe therefore that the absolute limit in dosage of vaccine is reached. According to his paper his dosage commences at something under 2,000 million germs, but he does not state what is the maximum.

By detoxication, according to my latest process, I have been able to give 25,000 million as an initial dose of most vaccines with a maximum of over 100,000 million. I have inoculated myself with doses of 150,000 million of *M. catarrhalis* detoxicated by my latest methods, without any appreciable reaction, and in some of my private cases I have reached doses of 400,000 million of mixed coryza vaccine. Facts of this nature would certainly appear to show that Dr. Jenkins's assertions are erroneous and that the limits of detoxication are by no means yet reached.

In his own paper he quotes from Vaughan, but he does not appear to have studied Vaughan's work sufficiently. Thus Vaughan clearly states that "superheated steam at 184° C. disrupts the bacterial cells, but does not destroy the intracellular poison." "Heating the cellular substance of the colon bacillus in physiological salt solution at 140° C. in the autoclave does not destroy or even weaken the poison." Farther on in his book Vaughan then proceeds to show how this intracellular poison can be removed. Dr. Jenkins's statements are therefore in direct opposition to Vaughan's researches and my own work.

Finally, I would like to say that the autoclaving at 120°C. to which Dr. Jenkins subjects his vaccines is entirely unnecessary: any such drastic procedure has been proved to destroy the specific antigenic properties of any protein. Kolmer in his book on *Immunity and Specific Therapy*, 1917 (p. 333), points out that an antiserum to uncooked horseflesh will not necessarily detect cooked horseflesh in sausages, and that for the detection of boiled horseflesh a special antiserum to the boiled material may have to be used. I feel certain that if autoclaved sheep cells were injected into a rabbit very little haemolysis would be produced towards fresh sheep cells as a result. Finally, Dr. Jenkins says that he has never heard of cholesterolized heart extract being either prophylactic or curative in syphilis, and everyone agrees with this; but it is of no value in the argument. Noguchi states definitely that in doing the Wassermann reaction we are not testing for syphilitic antibodies, and Dr. Jenkins would be well advised to avoid such statements until the nature of the Wassermann reaction is more thoroughly understood.—I am, etc.,

London, May 30th.

DAVID THOMSON.

SIR,—I should perhaps have made it clear that when I said that an antigen proves nothing concerning efficiency as an immunizing agent I desired to be taken literally—that is to say, that because a substance is an efficient antigen that fact is not in itself a proof that it is also a good immunizing agent. I do not deny that it may be so. But I cannot accept the theory that proved antigenic efficiency is full and sufficient proof of immunizing power against the whole organism. I quoted the Wassermann reaction as an undeniable example of an antigen utterly devoid of immunizing power. Dr. Priestley's experience of detoxicated vaccines seems to have been disappointing and is at variance with my own. I also have found that they do not always succeed, but I have found that they succeed more frequently than does the older type of vaccine. I have been given to understand that my belief in the superiority of these newer vaccines is shared by those who have used them.—I am, etc.,

C. E. JENKINS.

Manchester, June 3rd.

ENGLISH CYSTOSCOPES.

SIR,—I wish to make a slight correction in my article on "Pyelography" in your issue of May 13th, in justice to the Genito-Urinary Manufacturing Company, who have called my attention to this slip. In that article I stated that the special model of catheterizing cystoscope which they make for me is nowhere larger than 24 Charrière; this was an error for 22 Charrière. The point is one of considerable importance, as the smaller the calibre of the cystoscope the more easily can it be passed without causing pain, especially in the male subject. Despite the narrow calibre of the cystoscope, there is no reduction in the size of the field as compared with the larger German models.

I should also like to take this opportunity of emphasizing one or two other points in connexion with English cystoscopes. Before the war we were dependent on Germany and, to a less extent, America for cystoscopes, but since the war we have been driven to making cystoscopes in England, and this has been accomplished by the getting together of the actual workers themselves, who have banded themselves together as the Genito-Urinary Manufacturing Company, resolved to try and beat the Germans at their previous monopoly. I think everyone will agree that the object is praiseworthy and one that merits all possible encouragement from the profession. I think it can be stated confidently that the English cystoscopes as made by this company are now second to none in the world and in many of their new features show a considerable advance beyond the American and the German models.

Until recently it was very difficult to produce an English cystoscope at a price that could compete with the German cystoscopes owing to the fall in the German exchange; but the company informs me that their prices have now been so far reduced as to fall into line with the prices of the German instruments of similar type. At first when the new company was experimenting with new models it had to sink a good deal of money and had to charge high prices, and I believe that this perhaps kept some English doctors from buying English cystoscopes as they preferred to get them at the German prices from Germany.

I would like to appeal to English instrument makers and to English doctors to support home industries and to pause

and consider English cystoscopes as far as possible before sending to America or Germany. There is a tendency amongst certain people still to send to Germany for instruments, especially as they think that they are cheaper; but now that the prices have been equalized there is really no excuse in encouraging German industry at the expense of our own workers. That this industry can become an important one will be realized if it is known that before the war one German firm (so they informed me) were accustomed to sell as many as 3,000 cystoscopes a year.—I am, etc.,

London, W.I., May 29th.

FRANK KIDD, M.Ch.

HIP-JOINT DISEASE IN THE TUBERCULOSIS DISPENSARY.

SIR,—In the course of a few years of work in a tuberculosis dispensary, following on a longer period of general practice, some experiences in the latter are explained. During fifteen of the early years of a new and rapidly growing colliery village one saw many cases of joint trouble in the young population. The hip-joint was, as usual, the commonest sufferer, and fortunately one was able to see the cases in quite early days. In accordance with the teaching of Howard Marsh rest in bed in this class of patient was secured for at least a couple of weeks by placing a good-sized fly-blister over the joint. This procedure never failed one in keeping the child lying down long enough to get rid of the trouble; and fortunately in no case was there lameness or crippling.

Work in the dispensary has explained this good fortune, the reason obviously being that few of the cases were tuberculous, but rather local manifestations of some other general infection cured by the enforced rest and the counter-irritation produced by the blister. Since the patients of one's area of dispensary work are chiefly of the same class opportunity of seeing cases which have not ended so satisfactorily somewhat frequently occurs. Varying degrees of lameness and crippling are seen in little patients—boys generally—who hobble about seemingly without pain and discomfort, and whose x-ray pictures show surprisingly little or no trace of bone or cartilage change—the lameness evidently caused by the luxation of the soft tissues resulting from movement when rest was needed by the inflamed joint. The von Pirquet test is usually negative, and one generally learns that the initial lameness followed an attack of scarlet fever, measles, or bronchopneumonia, and the trouble at first usually labelled "growing pain" or "a bit of rheumatism."

Tubercle infection in addition no doubt alters the picture and the end-result (especially if the bone-setter has "put the joint in"), but it seems a pity that these comparatively innocent cases should not get the initial necessary rest so easily obtained. Of course it is wise to warn the friends of the urinary trouble, sometimes amounting to strangury (but soon disappearing with the rest in bed), which results from the use of the fly-blister. It is reasonable to think that cases of Perthes's disease and coxa vara may be the result of want of early and complete rest of these non-tuberculous joint affections.

The following are notes of a case seen in the last few days:

Male, aged 6 years, lame eighteen months, but worse last six months. Pertussis and bronchopneumonia about two years ago. Wasting, shortening, flexion and abduction limited; no pain, and nothing acute in symptoms. Von Pirquet negative. Radiologist's report: "No evidence of alteration in bone or cartilage, or any acute disease of the hip-joint."

—I am, etc.,

Newport (Mon.), May 27th.

J. LEWIS THOMAS.

THE OUTLOOK IN TROPICAL HYGIENE.

SIR,—In his letter on the above subject in your issue of May 20th Colonel Balfour, C.B., states that so far as he is aware, "no diploma in sanitary science as applied to the tropics yet exists for sanitary inspectors." Whilst this is applicable to lack of action in Great Britain, considerable progress in this respect, at least in one part of the tropics—India—has been made in providing sound technical education for this class of men, who form the backbone of applied hygiene. In November, 1893, the Local Government of the Madras Presidency was advised to take action in this matter. By December 10th, 1894, the conu

bodies, the sanctioning of funds and final approval by that Government of the course of education recommended were secured. Since that date no sanitary inspector could be nowly entertained by any authority in the whole area of the Madras Presidency unless he possessed the certificate of qualification showing that he had attended this course, and passed the examination prescribed by the Government ruling. The Madras Government was thus the first in the tropics to require compulsory technical training of sanitary inspectors. That the training afforded is efficient may be judged without my taxing your space with details. I may state that the general educational standard for admission to the course is the matriculation examination of the Madras University, which is equivalent to the F.A. of the Calcutta University. Assistant sanitary inspectors attend courses of physiology, bacteriological demonstrations, and theoretical hygiene, under the professors of the Madras Medical College, and practical hygiene under selected sanitary officers. Qualification as sanitary inspector demands a very complete additional course and examination in minor sanitary engineering. Rulings exist (which rival conditions of medical registration in Great Britain in stringency) affecting maintenance of technical knowledge and reputable conduct. In these circumstances, it was not considered necessary to accept aid from the Royal Sanitary Institute, which sought to ally itself with the education of sanitary inspectors in India, about fifteen years after this had been duly organized in the Madras Presidency. Indeed, by 1909, there were 683 sanitary inspectors qualified under the scheme sanctioned by the Madras Government, of whom 554 were in active employment; 65 per cent. of these men were Brahmins by caste, and practically the remainder of other high castes—a great advantage in effecting many necessary sanitary measures without causing discontent among the masses. In 1911 the Government of India, after referring to progress thus made in the Madras Presidency, urged action by all local Governments, and consequently general attention is being given in the various Provinces to the subject at the present time.

I understand Colonel Balfour especially looks to the Royal Sanitary Institute to arrange for sanitary inspectors being trained for work in the tropics—a matter also urged by him at the International Medical Congress of 1913. If that be so, it will certainly require an effort on the part of that able sanitary body suitably to modify its doubtless well-intentioned method of aiding the tropics—in practice limited to bestowing the blessings of its seal at Rs. 25 a head on students educated locally, as set forth in its arrangements with the Bombay Government in 1908-9.

A man who does not possess an intimate knowledge of the habits and customs of the tropical people dealt with is not likely to be of much utility for a considerable period after joining an appointment; the man locally educated has this advantage. On the other hand, a man educated in Great Britain has the opportunity of gaining knowledge of more diverse and radical engineering works than one educated solely in the tropics; and this is of importance, as without a sound knowledge of minor sanitary engineering the value of sanitary inspectors in the tropics is greatly diminished.

It should, however, be possible to evolve a scheme for a "diploma in sanitary science as applied to the tropics" for sanitary inspectors which will take cognizance of these facts, and thus progress beyond the stage of a commercial treaty with authorities in the areas concerned.—I am, etc.,

Hendon, June 3rd.

W. G. KING, Colonel I.M.S. (ret.).

REMOVAL OF THE NIPPLE IN THE PROEMIAL BREAST.

SIR,—Sir G. Lenthal Cheate, in his interesting paper on cancer of the breast (June 3rd, p. 869), states that in removing the proemial breast the nipple is not removed, care being taken to separate it from the parts immediately beneath.

I have recently on two occasions had to remove the nipple at subsequent operations for attacks of chronic inflammation in it and the skin immediately surrounding it, apparently due to interference with the blood supply.

As the only objection to its removal is a sentimental one, I think a more satisfactory result is obtained by excising it.—I am, etc.,

Leicester, June 4th.

F. BOLTON CARTER.

THE CASE OF MR. F. W. AXHAM.

SIR,—As we have been assured in repeated and uncontradicted announcements that the honour recently conferred on Mr. H. A. Barker owes its origin, at least in part, to the efforts of certain leading members of the medical profession, it would seem inevitable that a not less strenuous attention should now be directed to the position of Mr. F. W. Axham. It will be remembered that some years ago Mr. Axham's name was removed from the *Medical Register* because of his active association with Mr. Barker's work. I make no pretence either to estimate the value of this work or to review the decision of the General Medical Council. It is, however, certain that but for Mr. Axham's co-operation Mr. Barker's activities would either have been restricted or, alternatively, would have cost much suffering to many of his patients. The profession can hardly defend a position in which, while the principal, by medical efforts, is promoted to honour, his colleague, by a medical verdict, is declared "guilty of infamous conduct." That both should come under condemnation, or that both should be approved, is at least a consistent judgement. But that one should be exalted and the other contemned stands open to obvious reproach.—I am, etc.,

C. O. HAWTHORNE.

London, W. 1, June 4th.

Obituary.

W. H. R. RIVERS, M.D., D.Sc., F.R.S.;

Fellow and Praelector in Natural Sciences, St. John's College, Cambridge.

DR. W. H. R. RIVERS was taken suddenly ill early on Whit-Sunday with symptoms pointing to an acute abdominal lesion and died the same evening. He had attained great distinction as an anthropologist and experimental psychologist, and had recently been accepted as the candidate of the Labour party for the representation of the University of London in the House of Commons.

William Halse Rivers was born in 1864; he went to Tonbridge School and was a student of St. Bartholomew's Hospital; he graduated M.B. London in 1886, and M.D. of the same university in 1888. His work was recognized by the honorary degrees of LL.D. of St. Andrews and D.Sc. of the University of Manchester, and in 1898 when he became a Fellow of St. John's College he was made M.A. *honoris causa* in the University of Cambridge. He became a Fellow of the Royal College of Physicians of London in 1899, gave the Croonian lectures on the Action of Drugs and Fatigue in 1906, and in 1915-16 two courses of FitzPatrick lectures on Medicine, Magic, and Religion. He had promised to take part in a discussion on alcohol in the Section of Medical Sociology at the Annual Meeting of the British Medical Association at Glasgow.

It was as an anthropologist that his name first became known. He was a member of the Cambridge expedition to Torres Strait, and in addition to contributions to the reports of that expedition wrote on the history of Melanesian society, on kinship and social organization, and on dreams and primitive culture. He was President of the Royal Anthropological Institute and of the Folk-Lore Society.

At an early stage of his career Rivers had been house-physician to the National Hospital for the Paralyzed and Epileptic, and was afterwards lecturer on psychology at Guy's Hospital, as well as lecturer on physiological and experimental psychology in the University of Cambridge. In physiological investigation he was one of a company of workers long associated with Dr. Henry Head, and the results of their researches were recorded in the series of papers on the structure and functions of the afferent nervous system published in *Brain* during the first decade of this century. During the war he held the temporary rank of captain R.A.M.C., was medical officer to the Craiglockhart War Hospital and the Military Hospital, Magball, and psychologist to the Central Hospital, R.A.F. He thus maintained continuously his interest in psychology as well as in anthropology, and his friends were greatly impressed with the enthusiasm with which he turned from his more academic studies to clinical work in the branch of practical medicine that specially appealed to him.

His chief contribution to medicine was his remarkable

book on *Instinct and the Unconscious*,¹ first published in 1920, and described in its subtitle as "a contribution to a biological theory of the psychoneuroses"; in reviewing it shortly afterwards, we said that it opened up new lines of thought and would well repay the most careful study. A second edition of this book was published only a few months ago; in preparing it he made some alterations in the original text, mainly in connexion with the subject of dissociation, and added a couple of papers he had published in the interval. We may best indicate the attitude of Dr. Rivers to the present state of psychological medicine by a brief examination of this second edition. The object with which he wrote the monograph was to correlate the psychoneuroses with the concepts concerning the normal activities of the mind and nervous system held by biologists and physiologists. In the present highly specialized state of knowledge this is a difficult task, for it demands an expert acquaintance with branches of science seldom satisfactorily covered by one man. By his physiological work, his exceptional knowledge of psychology, especially of the more primitive races of mankind, by his considerable experience of the treatment of war psychoneuroses, and more particularly by his broad outlook, Dr. Rivers was eminently fitted to harmonize the facts of clinical psychology with the principles of biology and physiology. While not a blind follower of Freud he was able to grasp the good points in the Viennese professor's work. He regarded many of the mechanisms suggested by Freud as well adapted to explain how the conditions underlying a morbid state produce the symptoms through which the state becomes obvious. As the psychoneuroses depend essentially upon the abnormal activity of processes not ordinarily entering into consciousness, he devoted particular consideration to the general biological function of the process whereby experience passes into the region of the unconscious. Thus he illustrated the significance of suppression of psychological experience by a discussion of the phenomena of protopathic and epicritic sensation, as worked out in conjunction with Dr. Henry Head, of the relation between the optic thalamus and the cortex, and of the mass reflex. The ability with which this was elaborated was remarkable. The distinction between suppression and dissociation is made clear, and the different significance of the term as used in psychology, where it is so firmly and appropriately established, and in physiology by Drs. H. Head and G. Riddoch, leads to the suggestion that some other word should be found for the process so essential to the method by which such momentous contributions are being made to the physiology of the nervous system.

Psychological dissociation is defined as the process which experience undergoes when it is suppressed and acquires an independent activity and consciousness, as in a fugue. Suppression often exists without anything that can be called dissociation, and when there is definite activity of the suppressed content evidence of consciousness accompanying this activity, but cut off from the general body of consciousness, is absent. The biological need for the presence of dissociation among the potentialities of human behaviour is then discussed, and it is pointed out that regression corresponds closely with the process called devolution by Huxtings Jackson, who argued that in disease the organism tends to retrace the steps of its development. Thus hysteria, which is a protective mechanism, represents a recrudescence of the reaction to danger in an early stage of animal development. In anxiety- and compulsion-neuroses, the regression is characterized by the emotional disturbance natural in childhood; and mania is regression to an extremely primitive state, but is complicated by disorder and disintegration, and so this feature is less obvious than in the milder forms of psychosis and in the psychoneuroses.

Dr. Rivers's contributions to science covered a wide field and always bore the mark of distinction, but to medical men this work will long remain the most familiar milestone.

The withdrawal of Dr. Rivers's influence at this moment is a very great loss to practical medicine as well as to science. By the width of his knowledge and the sobriety of his judgement in general psychology, informed as it was by a profound acquaintance with anthropology, he had already illuminated many dark places in psychological medicine, and we were looking forward to his guidance in the future.

The funeral service was celebrated at St. John's College Chapel on June 7th.

GORDON LEY, F.R.C.S. Eng., M.R.C.P. Lond.,
Gynaecologist to the Hampstead General Hospital.

ONE of the two passengers in the ill-fated aeroplane which fell into the English Channel on the morning of June 3rd was Mr. Gordon Ley, F.R.C.S., who held a prominent place among the younger gynaecological surgeons in London. He was travelling on professional business to Paris in a French machine, which after passing over the coast dived suddenly into the sea from a height of 1,500 feet, two or three miles off Folkestone, and the pilot and both passengers lost their lives. Dr. G. H. Varley, of Cadogan Place, who was on the Bonlogne packet, was taken at once in a boat to the wrecked aeroplane, but only in time for the sad task of recognizing the body of his colleague.

Gordon Ley was born in 1886 and studied medicine at the London Hospital, where he won a scholarship in obstetrical medicine in 1907, and after qualifying was assistant for a time in the Pathological Department. He obtained the diplomas of M.R.C.S. and L.R.C.P. in 1908, the Fellowship of the Royal College of Surgeons in 1912, and the Membership of the Royal College of Physicians in 1913. His earlier hospital posts included those of resident medical officer to Queen Charlotte's Lying-in Hospital, pathologist to the Chelsea Hospital for Women, and gynaecologist to the Eastern Dispensary, Leman Street. He was afterwards appointed obstetrical registrar and tutor at Charing Cross Hospital, assistant obstetric surgeon to the City of London Maternity Hospital, and gynaecologist to the Hampstead General Hospital. At the Annual Meeting of the British Medical Association at Newcastle-upon-Tyne last summer, Gordon Ley was one of the honorary secretaries of the Section of Obstetrics and Gynaecology, and gave valuable assistance to us in reporting its proceedings for the *BRITISH MEDICAL JOURNAL*. Only last week we announced that he would read a paper on primary carcinoma of the ovaries in the same Section at the forthcoming Annual Meeting at Glasgow. For some years past he had been a regular attendant at the meetings of the Obstetrical Section of the Royal Society of Medicine, and contributed several papers of much merit to its *Proceedings*. He was also the author of an article on utero-placental haemorrhage which appeared in the *Journal of Obstetrics and Gynaecology* last year. Thus a professional career of great promise has been cut short with tragic violence.

The inquest was held at Folkestone on June 6th, and Mr. Gordon Ley's brother, Dr. R. L. Ley, of Great Yarmouth, gave evidence of identification. On the same afternoon the body was laid to rest in Folkestone Churchyard.

LOUIS RANVIER,

Honorary Professor of General Anatomy, Collège de France.

NOR a few English members of the profession—now, indeed, all in the sero and yellow leaf—will recall the interest, it may almost be said the emotion, with which they first read the *Traité d'anatomie pathologique* by Cornil and Ranvier. It was as the lifting of a blind letting a flood of sunlight into a dark room. Cornil was a man of wide generalizations, sometimes hazardous; Ranvier the man of detail and precision. Histology, normal and morbid, had then a great attraction for the scientific-minded among the younger men in medicine. Experimental medicine was immature, but histology, though the refined methods of to-day were unthought of, afforded means of getting down to a solid basis of demonstrable facts which the then available methods of clinical observation could not afford. Physiology stood aloof. It was making great strides, but had forgotten the maxim of Sharpey, and indeed of John Hunter, ever to remember that whatever else it was or might become it was the foundation of medicine and should be taught to medical students with that fact always in the mind of the teacher. Cornil and Ranvier had begun with a small private laboratory in Paris, where they gave special courses for students, but Cornil soon obtained academic promotion, and Ranvier, having attracted the attention of Claude Bernard, was in 1867 appointed the first director of the laboratory of histology newly established at the Collège de France; later on he became the first occupant of the chair of general anatomy. He worked incessantly at his favorite subject, wrote a *Traité technique d'histologie*, in which every statement was founded on or tested by his own observations, became a member of the Académie de Médecine and des Sciences, and retired some twenty years ago with the title of honorary, or emeritus, professor to an

¹ *Instinct and the Unconscious. A Contribution to a Biological Theory of the Psychoneuroses.* By W. H. R. Rivers, M.D., D.Sc., LL.D., F.R.S. Second edition, revised. Cambridge University Press, 1922. (Demy 8vo. pp. 277. 16s.)

estate he had near Roanne. He has died at the age of 87, leaving part of his fortune to that town for the crection of a sanatorium for tuberculosis.

LIEUT.-COLONEL C. W. OWEN, C.M.G., C.I.E.,
I.M.S. (Ret.).

LIEUT.-COLONEL CHARLES WILLIAM OWEN, C.M.G., C.I.E., Bengal Medical Service (retired), died at Hankham, Sussex, on May 23rd, aged 69. He was the son of the late Arthur Smith Owen, merchant, of Southampton, and was educated at Paris, at St. Thomas's (where he held an exhibition), and at Brussels. He graduated as M.A. Paris in 1875, and took the M.R.C.S. and L.R.C.P. Lond. in 1874. After holding a commission for a short time as surgeon in the Royal Naval Artillery Volunteers, he entered the I.M.S. as surgeon on September 30th, 1876; he became lieutenant-colonel after twenty years' service, and retired on March 15th, 1902. Among other appointments he held in India he was surgeon to the Commander-in-Chief (Lord Roberts), medical adviser to the Maharaja of Patiala, and residency surgeon, Jaipur. He served in the Afghan war of 1879-80, when he was present at the action of Charasiah, took part in the cavalry action in Chardih Valley, in which he was slightly wounded, and in the operations at and around Kabul in December, 1879; he was mentioned in dispatches, and received the medal with two clasps. Subsequently he served in the Egyptian campaign of 1882 on the headquarters staff, was present at the battle of Tel-el-Kebir, and received the medal with clasp, and the Khedive's bronzo star. He was medical officer to the Russo-Afghan Boundary Commission in 1885-87, and served with the headquarters staff in the Mohmund campaign of 1893 on the north-west frontier of India, receiving the frontier medal with a clasp. He was decorated with the C.I.E. on May 24th, 1881, the C.M.G. on February 15th, 1887, the Afghan Order of Hamat in 1886, and received a Good Service Pension on April 29th, 1918. After his retirement he settled in Sussex, where he was a justice of the peace, and did a large amount of county administrative work. He was vice-chairman of the Eastbourne Rural District Council, member of the board of guardians, chairman of the Hailsham grouped council schools, member of the Sussex Education Committee, Land Tax Commissioner, county director of the British Red Cross Society for Sussex, member of the East Sussex War Pensions Committee, and during the war, from 1915 to 1920, surgeon-major of the Sussex R.A.M.C. (Volunteers). He was twice married: first, in 1878, to the eldest daughter of the late Horace Barry, who died in 1920, and secondly, in 1921, to the elder daughter of the Rev. H. Hopley.

The Services.

DEATHS IN THE SERVICES.

Colonel William Henry Baut Clapp, R.A.M.C. (retired), died at Wallasey on March 26th, aged 82. He was the son of Purveyor W. H. Clapp, was born at Douglas, co. Cork, on December 16th, 1839, and educated at Queen's College, Cork, graduating M.D. of the Royal University of Ireland in 1860. He subsequently took the M.R.C.S. in 1862 and the F.R.C.S. Edin. in 1889. He entered the army as assistant surgeon on October 1st, 1862, served in the 54th Foot (2nd Dorset) in the old regimental days, became brigade surgeon in 1890, and retired at the end of 1894. He served in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star.

Surgeon Lieutenant-Colonel Herbert Boyd, Bengal Medical Service (retired), died at Birchington on April 22nd, aged 74. He was a Canadian, born at St. John's, New Brunswick, on May 22nd, 1847, and was educated at Harvard, where he graduated as M.D., afterwards studying at St. Mary's and Paris, and taking the M.R.C.S. and L.S.A. in 1866. He joined the Indian Army as assistant surgeon on October 1st, 1869, and retired on January 15th, 1895. His whole service was passed in military employ. He served on the north-west frontier of India in the Jowaki campaign of 1877-78 (medal with clasp); in the Afghan war of 1878-80, at the capture of Ali Masjid, and forcing of the Khaibar Pass (medal with clasp), and in the Hazara campaign of 1893 (clasp).

Captain Archibald Lang MacLean, M.D., M.C., Australian Army Medical Corps, died at Sydney on May 13th, after a long illness, due to gas poisoning on active service. He was educated at Sydney University, where he graduated M.B. and Ch.M. in 1910. The Military Cross was conferred upon him on February 1st, 1919. Since the war he had served with the Australian Antarctic Expedition.

Flight Lieutenant Edward Gerald O'Gorman, M.B., Royal Air Force, was killed at Heliopolis in Egypt on April 29th by the crashing of an aeroplane which he was piloting. He was a native of Fermoy, co. Cork, and was educated at the Cork Medical School; he graduated as M.B., B.Ch., and B.A.O. of the National University of Ireland in 1918. He joined No. 70 squadron of the

Royal Air Force in Egypt in April, 1920, was appointed flight lieutenant three months later, and in June, 1921, became medical officer of the Flying Training School at Abu Sueir, Palestine.

Dr. Roderick McLeod, Bengal Uncovenanted Medical Service (retired), died at Oban on April 18th, aged 82. He was educated at Edinburgh University, where he graduated M.D. in 1862, just sixty years ago, taking the L.R.C.S. Ed. in the same year, and soon afterwards was appointed an uncovenanted medical officer in Bengal, where he held the civil surgeoncies of Chapra and Gaya, and afterwards served as health officer of the port of Calcutta, retiring about thirty years ago. He was a brother of the late Mr. James McLeod, C.I.E., of Lal Seriah, Champaran, well known all over India, and a cousin of Colonel Kenneth McLeod, K.H.P., I.M.S.

Lient.-Colonel J. W. West, C.M.G., R.A.M.C., is appointed honorary surgeon to the King, and is granted the brevet rank of Colonel, vice Major-General Sir M. P. C. Holt, K.C.B., K.C.M.G., D.S.O. (retired).

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 3rd the following medical degrees were conferred:

M.B., B.Ch.—H. V. Edwards.
B.Ch.—G. C. Wells-Cole.

UNIVERSITY OF LIVERPOOL.

THE first course of study for the degree of Master of Orthopaedic Surgery (M.Ch.Orth.) instituted at the University of Liverpool, will commence in October next. Full particulars can be obtained on application to the Director (Sir Robert Jones), or to the Dean of the Medical Faculty.

UNIVERSITY OF MANCHESTER.

DR. JOHN SUTCLIFFE has resigned the post of clinical lecturer in mental diseases, and Dr. R. A. Webb that of demonstrator in pathology.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have, after examination, been admitted as diplomates in Public Health: Ellen D. Anderson, Ba Kin, J. M. Campbell, J. Frew, K. A. Gilchrist, T. E. Hastings, D. Heard, S. J. Henderson, T. McGowan, R. J. Peters, C. B. Reekie, Margaret T. Rutherford, Marguerite L. Sclanders, D. M. Scrimgeour, Margaret M. Stuart, R. P. Smith, G. Taylor, Anna M. Williams.

Medical News.

DR. ALEXANDER BLACKHALL-MORISON has been elected a corresponding member of the Medico-Chirurgical Society in Edinburgh.

PROFESSOR G. ELLIOT SMITH, F.R.S., and Professor J. I. Hunter will describe a reconstruction of the Piltdown skull at a meeting of the Royal Anthropological Institute, 50, Great Russell Street, W.C.1, on Tuesday next, June 13th, at 8.15 p.m.

SIR GEORGE HENRY MARINS, G.C.M.G., C.B., F.R.C.S., has been appointed a director of the Clerical, Medical, and General Life Assurance Society, to fill the vacancy caused by the death of Sir Alfred Pearce Gould.

THE annual general meeting and dinner of the Cambridge Graduates' Medical Club will be held on Wednesday, June 21st, at the Imperial Restaurant (Oddenino's), Regent Street, London, W., at 7.30 p.m., with Mr. T. H. Kellock, Vice-President, in the chair. Members intending to be present should communicate with Mr. R. Davies-Colley, C.M.G., 10, Devonshire Place, W.1.

THE annual dinner of the Harveian Society of London will take place on Thursday, June 15th, at the Café Royal, Regent Street, at 7.30 p.m., with the President, Sir William Willcox, in the chair.

DR. GUSTAVE MONOD, M.R.C.P. Lond., will give a course of demonstrations (in English) on practical hydrology at the Thermal Hospital in Vichy, from June 19th to 26th. The subjects to be dealt with are modern treatment at spas of diabetes, gout, enteroptosis, hepatism, and disorders of the sympathetic system. Further particulars can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE annual general meeting of the Röntgen Society will be held at the Institution of Electrical Engineers, Savoy Place, W.C.2, on Tuesday next, at 8.15 p.m. A paper on German apparatus for the production and measurements of x rays for deep therapy will be read by Drs. F. L. Hopwood and E. A. Owen, and various methods and instruments will be demonstrated by other members.

H.R.H. THE DUKE OF CONNAUGHT will distribute the prizes at St. Thomas's Hospital Medical School in the Governor's Hall on Wednesday, June 21st, at 3 o'clock. After the ceremony there will be tea and music on the terrace.

WE are informed that the Advisory Committee of the Tropical Diseases Research Fund has called the attention of the governments of the various colonies and protectorates to the use of antimony in leprosy and syphilis, and also that the Turkish authorities intend to test the drug in leprosy.

AT a meeting of the Cardiff Medical Society on May 9th Dr. D. R. Paterson gave an account of the history of medical endoscopy from the earliest times to the end of the eighteenth century. He dealt more particularly with the examination of the nose, mouth, and ear cavities, the uterus, and rectum. He traced the beginnings of endoscopic methods in Greek medicine and pointed out their relatively high development in Roman times, as evidenced by the finished instruments found in Pompeii. The address was illustrated by lantern slides.

DR. J. LIONEL STRETTON has been appointed a justice of the peace. He became surgeon to the Kidderminster Infirmary in 1882, and was appointed a consulting surgeon a few months ago. He has thrice been chairman of the Worcestershire Division of the British Medical Association, and was chairman of the Worcestershire Medical War Committee throughout the war. Last year he was entertained by his colleagues at a complimentary banquet and received a presentation of plate.

WE mentioned a short time ago that the Society of Apothecaries of London had given up its retail business. It has now taken the same course with its wholesale business, which has been taken over by Messrs. Randall and Wilson, Limited, of Southampton.

THE Cowdray Club, 20, Cavendish Square, W.1, will open its doors to members on June 22nd. This club owes its existence to the munificence of Lord and Lady Cowdray, and nurses and other professional women are eligible for membership; there is a special reduction in the subscription to members of the College of Nursing.

THE new buildings of the Hospital Saint-Michel, Paris, erected through the generosity of the Baron and Baroness Pierre de Guinzbourg, were opened on May 29th.

A SPECIAL intensive post-graduate course in cardiology will be held at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, from July 3rd to 15th. The fee for the course is £7 7s. Inquiries should be addressed to the Dean, Dr. B. T. Parsons-Smith, at the hospital.

MESSRS. WATSON AND SONS, LTD., Sanic House, Parker Street, London, send us a small waistcoat pocket pamphlet, in which, in addition to calling attention to what they are doing to advance methods of protection for x-ray and radium workers, they publish the reports of the X-ray and Radium Protection Committee. It also embodies a report from the National Physical Laboratory on an installation which they have recently supplied and erected.

THE Argentine Medical Syndicate, which was founded last year, has already enrolled over 300 members; it was soon followed by the foundation of a similar syndicate in Uruguay. The aim of these organizations is stated to be not only to promote the interests of the medical profession but to awaken in medical men the consciousness of their importance in general progress.

A SPECIAL course on orthopaedics will be held at Berck-Plage, under the direction of Dr. Calot, from August 7th to 13th. The course is intended for medical practitioners and will be of a practical nature; the English language, as well as French, will be used at the demonstrations. The fee is 150 francs, and particulars may be obtained from Dr. Fouchet, Institut Calot, Berck-Plage, Pas-de-Calais.

THE professional jubilee of Dr. Espina y Capo, of Madrid, is shortly to be celebrated by presenting him with a portrait bust, and by fixing a memorial tablet to the wall of his clinic.

DURING the first six weeks of 1921 the excess of births over deaths in France was 72,851 as compared with 179,356 in Germany during the first three months of the year.

THE Health Department of New York City states that though the number of cases of epidemic encephalitis notified to it is still relatively small it is increasing; more than 300 have been reported since the beginning of the year, with 70 deaths; in the corresponding period in 1920 there were 554 cases, and in 1921 there were 528.

A FARM of 200 acres in Alleghany County, New York State, has been presented by Drs. W. H. and S. V. Mountain to the Physicians' Home, an institution incorporated under the laws of the State of New York; it is to be converted into a home for indigent medical practitioners or their widows and orphans. It is stated that well-equipped laboratories for research work

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent out earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication understood to be offered to the BRITISH MEDICAL JOURNAL unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course necessarily for publication.

ACTIONS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Editor, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters of the editorial business of the JOURNAL be addressed to the Editor, Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Albion Westrand, London*; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER, *Albion Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the B.M.A. is Frederick Street, Dublin (telephone, 7, Dublin), and of the Scottish Office, 1, St. Andrew's Place, Edinburgh.

QUERIES AND ANSWERS.

ONYCHIA.

DR. V. C. HACKWORTH (Hove) asks for advice in treating a case of thread worms in a girl of 11, which has resisted all the remedies for several years.

STAINS FOR BLOOD FILMS.

DR. H. M. CADE (Bacteriologist to the East Suffolk County Council Pathology East Suffolk and Ipswich Hospital) writes: I advise Dr. J. Shulman to use Pappenheim's modification of May-Giemsa stain in his blood examinations? This stain is chromatic, and can be regarded as a universal stain. It is by no means as good as Giemsa's stain. Two solutions are used:

(a) May-Grünwald's eosin-methylene blue in methyl-alcohol.

(b) Giemsa's glycerin-alcoholic solution.

Staining is carried out as follows:

Four on the film the May-Grünwald stain, allow to act for minutes to fix, then add an equal quantity of distilled water to stain for one minute. Pour off stain and, without washing, add Giemsa stain diluted to about 15 drops in 10 c.c.m. distilled water to stain for fifteen minutes. Dry in the air.

I have used this stain extensively and find it to be reliable stains the nuclei quite as well as the old haematoxylin method. Jenner's stain is useless for distinguishing the various kinds of cells; its only merit is its property of staining brilliantly eosinophil granules. I cannot quite understand why Dr. Shulman has had difficulty with Leishman's stain; I have used it in many thousands of cases and found it to work well.

AREA OF VACCINATION VESICLES.

"D. S. B." asks what is the area of vesiculation which should be attained in small-pox vaccination.

"We understand that the official view is that the total should amount to one-half of a square inch and there should be half an inch of clear skin between the edges of the vesicles on the eighth day after the operation. There is no stipulation as to the size of the individual vesicles, the point being that the total area should amount to one-half of a square inch. The purposes of division are—to diminish inflammation, to promote healing, and to minimize the risk of insertion failure—the risk of failure of all the insertions.

INCOME TAX.

"L. T. D.'s" car transactions have been as follows: 1911, Wolsley 12-16 h.p.—first car—cost price £325; 1918, Singer 10-h.p., second car—cost £250; 1920, Wolsley sold for £175; 1921, Humber 11.4 h.p. bought for £73; 1921, Humber sold for £110.

The original outlay on the equipment of two cars was £573 and we think that the present equipment of one car and cycle may be taken as equivalent to the former, bearing in mind that one car was secondhand. On that basis the amount claimed would be as follows:

Additional outlay	£73	+ £700	= £773
Deduct amounts received for old cars	£160	+ £110	= £270
Expense of replacements	£403		

We assume that "L. T. D." need not deduct the £73 expenditure

"M. Q. B. G." has been Government M.O. in a British colony; he came to England on December 23rd, 1921, on six months' leave, but is retiring from the Colonial Service and is buying a practice as from September 1st, 1922.

* The profits of the practice are, of course, assessable on the basis of the three years' average as returned by the present practitioner; but he will be entitled to have that assessment divided between himself and "M. Q. B. G." as from September 1st, so that he will pay on the basis of 5/12ths of the gross assessment, leaving our correspondent liable on the remaining 7/12ths. We suggest, therefore, that the latter should explain the circumstances to the local inspector of taxes, and file a declaration of income, etc., including 7/12ths of the amount returned by his predecessor. If his full earnings should fall short of the sum assessed on him owing to some specific cause he can obtain a reduction to the actual earnings on application at the end of the year.

"E. M. J." inquires as to the appropriate deduction for "rent" in respect of the professional portion of the house which he owns.

* The amount of the total "rent" is determined by the valuation of the house as for the respective years for which the receipts and expenses are being taken—not as for the year of assessment. If the gross value is taken no deduction can be claimed for repairs or other expenses which are taken into account in reducing the gross valuation to a net basis; the more usual and the correct course is to take a proportion of the net assessment and to take into the professional expenses a similar proportion of the cost of repairs, etc. The extent of the work done does not appear to be material to the issue of what proportion of the value should be charged for tax purposes; that depends on the number and quality of the rooms used professionally.

"M. N." has for the past four months been receiving assistant's remuneration at £450 per annum, paying out of that a weekly sum to the firm's housekeeper for board and lodging. Previously he was earning about £2 a week in a hospital appointment.

* If "M. N." held a specific office at the hospital the emoluments there would fall under Schedule E, and could not be averaged now with the assistant's remuneration chargeable under Schedule D. No deduction can be made for the payments made for board and lodging.

LETTERS, NOTES, ETC.

A DIPLOMA IN TUBERCULOSIS.

DR. B. WALKER (Durham) writes: The time would appear to be ripe for general practising physicians, who see a large number of cases of diseases of children, to voice their opinions on this "tuberculosis craze" which, like a flood, is invading London, and has now crept over the Scottish border and the Roman Wall to Edinburgh. Thousands of poor London children, under the health section of public education, are dubbed "tuberculous" when there is not a vestige of fact pointing to the presence of that disease. Had we better start a diploma in diseases of children before we specialize in tuberculosis? I know that the eye enthusiasts have managed to coax Oxford to grant a diploma in ophthalmology, and I know also how this diploma is referred to socially by our lady friends as a diploma obtained "when he was at Oxford," leaving it to be inferred that the subject of conversation took his arts degree as everybody else had to do at that university. Specialization is already overdone, and general physicians are beginning to dread sending on their patients for opinion to many specialists. This aspiration to emulate American methods will land us in ridicule, and we shall be served rightly if the Faculty of Medicine gives its blessing.

MEDICINAL PARAFFIN AS A DRESSING FOR SEPTIC WOUNDS.

DR. MARGARET C. VIVIAN (Bournemouth) writes: Dr. White Robertson, in his book *Studies in Electro-Pathology*, emphasizes the value of medicinal paraffin as a dressing for septic wounds, and describes the excellent results he obtained by this means in the treatment of wounds during the war. A similar recent experience of my own may be of interest.

A young woman was badly bitten in the hand by a dog. Three punctured wounds were inflicted, the worst being two deep holes, one on each side of the base of the dorsum of the second finger, where the dog's teeth had gripped. The accident took place at 7 p.m. on a Saturday, and I saw the patient half an hour later. The hand had begun to swell, and there was a good deal of bleeding. After holding it under the tap for a few moments, I applied a pad of lint soaked in medicinal paraffin covered with a piece of oil silk. The next day the hand was very much swollen and discoloured, and the patient complained of pain and throbbing in the wounds, and the glands above the elbow and in the axilla were enlarged and painful. The paraffin dressing was renewed. On Monday morning the swelling had entirely subsided, there was no pain, and the patient could move her fingers freely. A week later the wounds had completely healed.

THE TREATMENT OF PNEUMONIA.

DR. F. C. McCOMBIE (Chahua P.O., Assam) writes: With reference to Dr. A. J. Mathison's claim for potassium iodide and creosote as a specific for lobar pneumonia, in your issue of March 11th (p. 420), I may mention that I am in medical charge of a group of tea estates in Upper Assam, on each of which I have hospitals, both large and small, suitable to the requirements of the estate, in charge of Indian subordinate medical men, of varying degrees of professional ability. The diagnosis is in most cases checked by me at my periodical visits, and clinically I have no doubt we are dealing with frank lobar pneumonia among coolies. My attention was drawn to this treatment in 1914, and I issued a circular that all cases of pneumonia were to be treated with the "specific." After eight months I called for figures, which I give below. I also give the figures for the previous and also the following year, when I gave no special instructions for treatment, although most of my subordinates have continued the iodide and creosote mixture, preferring it on clinical grounds.

Year.	Cases.	Deaths.
1913	302	75 = 24.9 per cent.
1914 (eight months)	119	27 = 22.7
1915	231	53 = 25.1

THE INTERSTITIAL GLAND.

DR. NORMAN MACFADYEN (Letchworth) writes: With fear and trembling I venture to ask a question; it is possible it may show great ignorance of recent research. It has always seemed to me that in cancer there is degeneration accompanied by a furious uncontrolled growth of embryonic tissue. This may mean that the equilibrium of normal tissues has broken down and that Nature has attempted to heal the breach by a mild outburst of rudimentary cells. Now if by ligature of the vas deferens the normal cells can be revitalized, would it not be worth while in suitable cases—as for instance, in cancers which cannot be completely removed—to try this operation? If by this means equilibrium could be re-established, the uncontrolled forces might then be controlled.

A STEREOSCOPIC HEAD MIRROR.

DR. L. GIBBONS, writing from Bad Nauheim, Germany, has sent us a description, with photographs, of a stereoscopic head mirror (Relascope) devised by Dr. E. Wessely, assistant in the Vienna University Clinic for Diseases of the Throat and Nose. With it binocular vision, instead of monocular, can be employed in the examination of the upper air passages. It is stated that the head mirror is of simple construction and can be taken to pieces to be sterilized; it includes its own electric lighting attachment, and the eyes of the observer are protected against infection. The field of vision is very large, and for purposes of class teaching self-contained reflecting mirrors are attached, by means of which students can follow a demonstration. The mirror is made by the firm of C. P. Goerz, Vienna.

A "RAT BARRACK."

DR. J. A. HARAN, C.M.G. (Bath), writes: Whilst looking over Hall's *Ireland* (London: How and Parsons, 1841) I happened upon the following interesting note: "Mr. Russell has a 'rat barrack' on his premises. It is about 12 ft. long and 6 ft. broad, and the walls about 4 ft. high, with a coping-stone on the top that projects a couple of feet inside the wall—the inside of the wall is full of holes that just admit a rat's body, leaving his tail outside—the whole is covered with old boards; there are two passages for them to come outside into the yard, where they are fed and never disturbed; the consequence is they never go into his store where the bacon is; once every three months he closes the holes that communicate with the yard—he uncovers the walls, and the rats all run into the holes in the walls; their tails are 'hanging out,' when a man goes in, takes them one by one by the tails and throws them into a barrel, when they are all destroyed, to leave room for a fresh supply."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 24, 25, 27, 28, and 29 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 26 and 27.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at pp. 227, 228.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 472, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

544. Cutaneous Leishmaniasis.

BRAHMACHARI (*Indian Med. Gazette*, April, 1922) records four cases of kala-azar treated with intravenous injections of antimony which, within six months to two years after completion of the treatment, developed a cutaneous eruption resembling tuberculous leprosy. No lepra bacilli were found, and they showed no symptoms of kala-azar, but scrapings from the nodules contained kala-azar parasites. This shows that while visceral leishmaniasis may be cured by antimonial treatment a few leishmania may remain with their virus so attenuated as to give rise to the milder disease of cutaneous leishmaniasis. Full notes of one case are given in which there were papillomatous, leprotic-like nodules on the face, an erythematous appearance on the cheeks, forehead, and extremities, and extensively spread, slightly raised, brown patches on the trunk and limbs. There was no ulceration or scabbing, no anaesthesia, loss of knee-jerks, nor thickening of the nerves, and there were no eruptions on the mucous membrane of the mouth and nostrils, the patient complaining only of the unsightliness. Since the eruptions are due to leishmania infection whose virus has been modified by antimonial treatment the term "dermal leishmanoid" is suggested for the condition, on the analogy of the term "varioid" for small-pox modified by vaccination. MEGAW (*ibid.*) questions the proof that the condition is due to a modified virus, and considers the disease a leishmaniasis and not a leishmanoid, and, while congratulating Dr. Brahmachari on the discovery, suggests the nomenclature of "Brahmachari's dermal leishmaniasis" as being more appropriate.

545. Antimony in the Treatment of Leprosy and Hydatid Disease.

CAWSTON (*Journ. Trop. Med. and Hygiene*, February 1st, 1922) gives his experience of the treatment of leprosy and hydatid disease with intramuscular injections of colloidal preparations of antimony. The best results are obtained by pushing the drug until early signs of antimony poisoning occur. Four cases received from 1 to 3 c.cm., the ulcers healing after four days' treatment, with considerable improvement in the conjunctivitis and paralysis. Larger doses were given in two other cases, one receiving 20.5 c.cm. in nine days, by which time the discharging ulcers at the extremity of each finger and toe were healed. An acute case of tubercular leprosy with satyriasis of the face, conjunctivitis, and desquamation of both forearms was considerably improved by one injection of 1 c.cm. of Comar's colloidal preparation of sulphur and antimony. Encouraging results occurring in a case of hydatid disease treated with intramuscular injections of colloidal antimony and emetine are recorded in a lady previously operated upon for two pelvic hydatid cysts, and who developed another below the right costal margin with an eosinophilia of 16 per cent. Following intramuscular injections over a period of three weeks (totalling 38 c.cm. of colloidal antimony and 6½ grains of emetine hydrochloride) the eosinophilia fell to 8 per cent., and x-ray examination showed reduction of the tumour, giving a shadow similar to that shown in a case successfully operated upon twelve years previously.

546. Results of Dental Defects.

GIVEN (*Journ. Royal Naval Med. Service*, April, 1922), who made investigations into dental efficiency in the navy from examinations of 575 unselected officers and men as regards digestion and regular action of the bowels, found that intestinal complaints, past or present, were almost as common among men with sound teeth as among those whose teeth were deficient and defective, and that robust health from infancy frequently occurred in men without a sound opposing tooth. The experience among uncivilized races, in whom dental disease is comparatively rare, points to the almost entire absence of appendicitis, gastric and duodenal ulcer, cancer, and other abdominal complaints, and is suggestive of the two conditions having a common origin in civilized dietary. Comparisons between the dental condition of sweet-eaters and non-sweet-eaters show that sweet eating is only a predisposing cause of caries, and that it is not incompatible with the presence of good teeth. Caries is frequently found to reach an advanced stage without giving rise to either local or general symptoms, men in robust health often possessing very bad teeth. It is more than likely, however, that later results may occur from a slow intoxication giving rise to

arterial degeneration and premature senility, and possibly many of the deaths diagnosed as from heart disease after middle age are primarily due to arterio-sclerosis from this cause.

547. The Diagnostic Value of the Exercise Temperature in Tuberculosis.

WÜRTZEN and HOLTEN (*Hospitaltidende*, February 15th and March 1st, 1922) have investigated the rectal temperature of 130 persons before, directly after, and a considerable time after exercise. Twenty of these persons were healthy "controls," leading the carefully graduated life of a prison. All the tuberculous persons tested were afebrile; sixty of them were in the third stage of pulmonary tuberculosis. The exercise was slow walking on the level, lasting fifteen, ten, or five minutes. The authors found that healthy as well as tuberculous persons may show a rise of temperature after slight exertion, and that in one and the same person the same exercise may provoke a rise of temperature persisting forty minutes on one occasion and only five on another. This variability in the temperature reaction of one and the same person may also be observed in the subjects of tuberculosis. Both healthy and tuberculous persons may actually show a fall instead of a rise of temperature after slight exertion, and after the exercise temperature has fallen to the level at which the temperature stood just before the exercise there may be a second, inexplicable rise. On the whole, tuberculous persons react to slight exercise with a rise of temperature more frequently than healthy persons, but the exceptions are so numerous that this test is of practically no value in demonstrating tuberculosis.

548. The Bronchi and Lungs in Typhoid Fever in Children.

NOBÉCOURT (*Clinique et Laboratoire*, February, 1922) discusses the respiratory complications of typhoid fever in children under the headings of bronchitis, pulmonary congestion, pneumonia, and bronchopneumonia. The bronchitis may be generalized or localized at the apex or base. The lesions at the apex may sometimes simulate tuberculosis and give rise to a pseudo-tuberculous pulmonary syndrome. During the first week a mild form of bronchitis is the almost invariable accompaniment of typhoid, and is not associated with any subjective or functional symptoms. At a later stage the bronchitis may become more intense. Bronchopneumonia, which for a long time was regarded as a rare complication of typhoid fever, is really fairly frequent, being found in 10 per cent. of the cases (Hutinel and Darre). It is especially seen in young children, in whom it may appear at an early or late stage of the disease. In the early stage it assumes the form of capillary bronchitis, and may sometimes be the cause of death occurring rapidly. Late bronchopneumonia is usually found in severe attacks of typhoid fever. Acute pulmonary congestion may appear at the onset, at the height of the disease, or at the termination, and affect the apex, the base, or the middle portion of the lungs. It is not a severe complication in itself, but the gravity depends upon the intensity of the typhoid process. Lobar pneumonia chiefly occurs at the onset of the disease, and may mask the typhoid process (pneumo-typhoid). Defervescence commences on the seventh or eighth day, but is not complete, the temperature rises again, and the signs of typhoid fever become evident. Some of the broncho-pulmonary complications of typhoid fever are due to the typhoid bacillus, which is found in the sputum, the lungs, or pleural effusion, while others are the result of a secondary infection, especially during an epidemic of influenza.

549. Progressive Cerebral Hemiplegia.

GORDON (*Journ. Nerv. and Mental Dis.*, March, 1922) discusses the pathogenesis and differential diagnosis of progressive cerebral hemiplegia. Various pathological conditions occur—for example, oedema of a whole hemisphere, large areas of softening, partial or complete obliteration of the internal carotids, thrombosis of the Sylvian arteries, multiple foci of softening through arteritis of small cortical or central blood vessels, and tumour. Notes of five cases are given showing clinically common characteristics in that the paralysis developed in one or other extremity, and passed slowly from mere weakness in one limb to total hemiplegia. The face generally becomes involved simultaneously with the arm, and the sensations are invariably affected. Mild paraesthesia with weakness in one limb is the characteristic form of invasion, and there is no suddenness of onset as in apoplexy; but in all five cases the prodromal period showed

vertigo, with an unusually severe attack ushering in the onset of the unilateral paresis. Three of the cases showed marked oedema with deep softening of the cortex, and total obstruction of its main arterial supply, and in four of the cases there were distinct degenerative blood-vessel changes, the oedema and softening in the three cases penetrating through the entire thickness of the cortex to the white substance. In one case the internal capsule was softened but there was no oedema, and in the case due to a gliomatous tumour there was no oedema, and for many months no marked symptoms of intracranial pressure. These cases point to the conclusion that the condition may result from endarteritis, from arteriosclerosis, from obliteration of a large vessel, such as the middle cerebral artery, and from tumours, especially of the gliomatous type. In all cases of partial paralysis, syphilis must be borne in mind; the condition may also arise as the result of aneurysms of the basilar artery, and in tuberculous meningitis.

550. Dermato-polyneuritis and Erythro-oedema.

THURSFIELD and PATERSON (*Brit. Journ. Child. Dis.*, January-March, 1922) record the case of a previously healthy female infant, aged 10½ months, who was suddenly attacked by an undiagnosed, probably febrile infection. After some weeks of ailing, fretfulness, and anorexia it developed well-marked cutaneous, neuro-muscular, and mental symptoms resembling in many respects the condition seen in some cases of epidemic encephalitis. The face showed two patches of colour on the cheek and a reddened nose with a patch of branny desquamation on the forehead. There was a slight erythematous rash on the buttocks. The extremities were cyanosed, slightly oedematous, and cold, with the skin peeling off the fingers in large flakes; the finger-nails were not affected, but the toe-nails appeared to be deformed by the inflammation. The redness, cyanosis, and desquamation were limited to the hands and feet, the skin above the wrists and ankles having an almost normal appearance. The skin lesions obviously caused a good deal of irritation, but not so much as in eczema. Neuro-muscular involvement was shown by tonelessness of the muscles and extreme slowness of all muscular movements, but there was no tremor nor inco-ordination. When awake the infant kept up a slow, continuous movement, falling forward on the face and then slowly raising her head and bringing herself into a sitting position with a circular movement. The writers point out that an identical or closely allied disorder was described by Swift of Adelaide in 1914, and more recently by Jeffreys Wood of Melbourne, and in the United States by Weston, Byfield, and Manning Field. Thursfield and Paterson prefer the term "dermato-polyneuritis" to that of "acrodynia" used by Byfield, since the latter term ignores the neuro-muscular and mental symptoms. The condition is usually regarded as a "deficiency disease" or as a post-influenzal polyneuritis. The prognosis is good, complete recovery being the ultimate result. In the present case death was due to acute intussusception, and the autopsy failed to reveal any gross abnormality. PARKES WEBER (*Ibid.*) reviews the literature, and records with illustrations a case of erythro-oedema which apparently commenced in the first month of life and lasted till death at 3½ years of age. The cheeks, chin, nose, and ears were affected as well as the hands and feet. The soles were red, slightly desquamating, and deeply ulcerated. The hands were mutilated by the loss not only of nails but of portions of fingers also.

551. Hypertrophic Rhinitis in the Child.

GAND (*Rev. de l'otol. et de rhinol.*, March 15th, 1922), in his Paris thesis, states that the predisposing causes of hypertrophic rhinitis in children are cold and damp or, on the other hand, excess of precautions, or errors in diet, or causes inherent in the individual, such as adenoids, narrowness of the nasal fossae, and especially the constitution of the patient. Local and general disturbances result. The local symptoms are nasal obstruction, which is partial or complete, permanent or transitory, and occasionally an acute or chronic rhinorrhoea. The general disturbances consist of: (a) infective manifestations, such as pharyngitis, laryngitis, bronchitis, otitis, and gastro-enteritis; (b) trophic disorders, such as deformity of the thorax, maldevelopment of the facial skeleton, mental disturbance, and aprosexia; (c) reflex disorders of the cardiac and respiratory systems, nervous dyspepsia, and various spasmodic conditions. Three principal types of hypertrophic rhinitis may be described—namely: (1) a purely congestive type, which subsides under treatment with adrenaline 1 in 20,000 solution; (2) a hyperplastic type, which requires a stronger solution of adrenaline; (3) a myxomatous type due to polypoid degeneration of the turbinate bone. Treatment consists in cauterization with chromic acid after local anaesthesia with cocaine. Thirteen illustrative cases are recorded.

SURGERY.

552.

Prolapse of the Rectum.

DRUECK (*Canada Lancet*, January, 1922) describes complete prolapse of the rectum in which the entire rectum with all its coats is protruded from the anus, owing either to extreme mobility or elongation and weakening of the normal supports, or to a defect in the pelvic fascia permitting a hernia of the pelvic bowel. Three degrees may occur: the first closely resembling an incomplete prolapse commencing at the anal margin; in the second degree the prolapse commences above the anus, the rectum being invaginated through the anal canal; while in the third degree some portion of the sigmoid or colon becomes invaginated into the rectum, although it may not appear externally. Complete prolapse of the first degree is distinguishable from the incomplete variety in that the mucous folds, which run longitudinally in the latter variety, surround the prolapse in irregular crescentic folds in the former. Since the condition begins within the rectum and protrudes through the anal orifice a sulcus is present between the prolapsing gut and the anal margin, a feature which differentiates it from the incomplete type. Prolapse of the third degree constitutes a true intussusception of the upper rectum, sigmoid, or colon, even to the caecum, into the lower rectum, and only in extreme cases does the bowel protrude from the anus, owing to the fact that the rectum is capable of great distension at its lower end. Symptomatically there is usually a history of constipation, followed by irregular diarrhoea, but complete obstruction does not generally result. Laxatives are ineffective, but enemata give relief by lifting up the bowel from below and stimulating a reverse peristalsis. Compared with obstruction of the upper bowel, the condition is more chronic, less painful, the diarrhoea more pronounced, and vomiting variable. Manipulation often causes gurgling of the gas in the loops filling the anterior part of the prolapse where percussion gives a tympanitic note, while the posterior half is dull—a sign not present in the incomplete variety, where only mucous membrane is detached. After reduction a laxity of all the rectal muscles is present on digital examination, and on palpation of the anterior wall of the rectum a distinct hernial impulse will be observed on coughing.

553.—JUVARA (*Bull. et Mém. Soc. Chir. de Paris*, March 14th, 1922) describes the case of a woman who had undergone numerous operations, consisting of partial removal of the mucous membrane, for prolapse of the rectum. The results were bad and the patient's condition was worse than before the operation. He then carried out an operative procedure consisting of total resection of the mucosa, plicating the muscular layer and narrowing the anal orifice, with complete cure of the condition. The operation was performed as follows: The mucous membrane was dissected up with some difficulty as a result of the scar tissue round the orifice; the fibres of the external sphincter were thin and mixed up with the cicatricial tissue, and the muscle appeared less than normal, as a result of the previous operations. The mucosa was then dissected up on the inner side of the muscle layer, and the muscle was enfolded by catgut sutures passed transversely; by this means the canal was made smaller in proportion as he carried out the enfolding above the external sphincter. By means of several sutures passed transversely the muscle was drawn towards the posterior wall and the anal orifice was markedly narrowed. The operation was completed by suture and resection of the mucosa in the same way as in the radical operation for haemorrhoids. On introducing a finger into the anus a narrow canal is felt surrounded by a thick elastic wall, formed from all the muscular portion of the prolapse which the sutures have drawn to the end of the gut; the mucosa is felt lying over this. The operative procedure was simple, and the wound healed by first intention, the patient leaving hospital three weeks later cured. This method shows the advantage of resecting the mucous layer and employing the underlying muscle to build up a strong support for the lower end of the intestinal canal.

554.

Tuberculous Stricture of the Duodenum.

A. LOEW (*Wien. Arch. f. Inn. Med.*, April 5th, 1922) describes a case of duodenal stricture due to tuberculosis. The patient, a married woman, aged 39, had suffered from severe constipation ever since her first confinement at the age of 23. She had signs of adhesions in the right hypogastric and iliac regions. She was emaciated, and had symptoms of tuberculosis at the apex of the left lung. The abdomen was retracted, but there was no visible peristalsis and no ascites. There was some epigastric tenderness and a palpable tumour as large as a small apple in the right hypochondrium. A skiagram showed dilatation of the stomach with normal pylorus and dilatation of the first part of the duodenum, with a marked constriction at the junction of the first and

second parts. A posterior retrocolic gastro-enterostomy was performed, and the patient was discharged from hospital three weeks afterwards. Loew describes and illustrates the *post-mortem* appearances in a fatal case in a woman under Professor Erdheim, in which anterior and posterior retrocolic gastro-enterostomy with Braun's anastomosis had been performed. He also discusses the differential diagnosis of duodenal and pyloric stenosis due to neoplasms, actinomycosis, and syphilis, and observes that although tuberculosis of the small intestine is far more frequent in the lower third of the canal, a number of cases have been recorded by various continental observers in which duodenal tuberculosis was found in patients suffering from pulmonary tuberculosis.

555 Vaccines in Infections of the Urinary Tract.

WULFF (*Hospitalstidende*, March 8th and 15th, 1922) analyses the results of vaccine treatment of 100 cases of infection of the urinary tract in Røvsing's hospital in Copenhagen in the period 1911-20. Cases of gonorrhoea were not included, and in the overwhelming majority the coliform group was responsible for the disease. The author classifies his cases according as they were characterized by (1) acute febrile exacerbations or relapses or (2) by a comparatively mild and chronic course. There were 43 in the first class, 32 in the second. In the first class 21 patients were cured and 16 improved. In the second class 16 were cured and 10 improved. In a third class, containing 17 cases of pyelitis with calculi, there were 8 in which the calculi could not be removed. Of the remaining 9 patients, one was cured and 7 were improved. The author, who is greatly impressed by the importance of autogenous vaccine treatment, and who has come to the conclusion that spontaneous recovery is exceedingly rare in this class of case, notes that in about 80 per cent. recovery or definite improvement can be achieved by vaccines. In the remaining 20 per cent. vaccines prove impotent for some unknown reason. The most important effect of vaccine treatment is the cessation of relapses or exacerbations, and in many cases freedom from such exacerbations may be maintained for several years. The author recommends an initial dosage of 10 to 30 million germs, and in some cases he has increased the dose to 10,000 million germs.

556 Colectomy for Chronic Intestinal Stasis.

MARTEL (*Bull. et Mém. Soc. Chir. de Paris*, January 25th, 1922) records a case of chronic constipation of more than twenty years' duration which was cured by the operation of colectomy carried out in two stages. The indications for surgical treatment, he considers, are as follows: Constipation of long duration becoming progressively worse and where the patient's general condition shows a downward tendency; where radiological examination shows considerable delay in the passage of the barium meals; and where medical treatment after a prolonged period fails to relieve the condition. In these cases it is not difficult to prove the presence of stasis, but it is difficult to show that it is the cause of all the troubles from which the patient suffers. It is only by a process of elimination and after careful examination of the other organs that one can say that it is the colon alone which is the seat of the mischief and in consequence requires removal. Many patients have had their colons removed and have not experienced any relief after the operation. There is no doubt that in these cases the trouble is not merely mechanical, but that the degree of toxicity of the intestinal contents plays a large part. One has to consider between the operation of complete colectomy and more conservative procedures on the right colon. Martel does not consider that in chronic intestinal stasis conservative methods give such good results as complete colectomy. Removal of the right colon is not satisfactory. He always does the operation in two stages: The first consists of an ileo-sigmoidostomy by an end-to-side anastomosis; this is a safe operation, and has on several occasions cured the patients without removing the large intestine. If afterwards a second operation is required he removes the colon down to the ileo-sigmoidostomy; this operation is equally straightforward. The result of this procedure in the case reported has been most satisfactory.

557. A Statistical Survey of the Treatment of Fractures.

HANSEN (*Medicinsk Revue*, March and April, 1922) has compared the results obtained in the treatment of fractures at a large surgical hospital in Christiania before and after the introduction of Lane's osteo-synthesis with plates. His verdict is decidedly in favour of this procedure. In the first period, 1908-12, there were 273 fractures treated, the results being good in 73 per cent. and bad in the remainder. In the second period, January 1st, 1914, to July 1st, 1920, there were 354 fractures treated, and the results were good in 83 per cent. Thus there was an improvement of 10 per cent. in the second period, during which about 10 per cent. of all the cases of

recent fractures were treated by Lane's osteo-synthesis. The author admits that it is difficult to give a fair estimate of the value of Lane's work in a purely statistical analysis, and he supplements his statistics by a detailed account of his cases, fracture by fracture. He found that the factor of insurance had an appreciable effect on the ultimate results; of his insured patients only 46 per cent. were not in receipt of compensation, whereas 75 per cent. of the uninsured stated that recovery was complete. Among 48 cases of fractures of old standing admitted to hospital there were as many as 24 with pseudarthroses, and in another 14 cases admitted to hospital for recent fractures pseudarthroses developed in hospital. It is thus evident that even when a recent fracture is given the benefit of immediate and prolonged treatment in a large first-class hospital, pseudarthroses may develop. In several of these cases Lane's osteo-synthesis was performed, but the results were in many cases disappointing.

558.

The Intraocular Circulation.

LEPLAT (*Le Scalpel*, April 15th, 1922), after a preliminary account of the anatomy of the blood-circulation within the eye, describes recent work in relation to this and the tension of the globe. Changes in tension are generally due to changes in the mass of blood within the eye. The influence of the vasomotor nerve centres (in the medulla or in the choroid) is well known. Amyl nitrite raises the ocular tension by dilating the vessels, whilst adrenaline (dropped into the conjunctival sac) does not alter the tension within the eye. The systolic and diastolic pressure in the retinal vessels can be estimated by a measured pressure on the ball of the eye. General states of the circulation may be diagnosed by a study of the retinal circulation, although in certain cases they do not correspond. By using the tonometer of Schiötz, the pressure in the choroidal circulation can be estimated. In the glaucomatous eye the pressure is always higher in the prone than in the sitting posture.

OBSTETRICS AND GYNAECOLOGY.

559

Cervical Carcinoma and Pregnancy.

GROSS (*Zentralbl. f. Gynäk.*, April 15th, 1922) found cancer of the cervix in 0.065 per cent. of pregnant patients coming to a women's clinic; he believes, however, that the coexistence of cervical cancer and pregnancy is five times as frequent as these figures, which correspond roughly to the estimates of other observers, would seem to indicate. In the same period of time 34 other cases of cervical cancer were detected within twelve months of the last labour or abortion; in 24 of these it was thought possible to conclude with certainty that the malignant disease had been present during the gestation. Three-fourths of the cases were in women aged from 24 to 35. With regard to prognosis the writer believes that for cervical cancer operated on during pregnancy the outlook is more favourable than at other times; in explanation it must be remembered that cases detected during pregnancy are likely to be earlier cases than others, that clinical recognition of early cases is comparatively easy during pregnancy, and that in the pregnant subject Wertheim's hysterectomy presents less formidable technical difficulties than in others. The operative mortality in the 22 operable cases of the present series recorded was nil. For inoperable cases coming to observation within twelve months of delivery prognosis is bad; a more rapid course is run than in carcinoma cervicis in general. In the series under review radiotherapy was found ineffective, and cases whose inoperability was only established at laparotomy showed a primary mortality of 50 per cent. Prognosis is less good for cases coming to operation *post partum* than during pregnancy; although diagnosis is made early, the tumour cells have been subjected to the trauma of labour, bleeding and possibly infection during labour has diminished the patient's resistance, the operation is more difficult and its shock is less well borne.

560 Operative Treatment of Infection following Abortion.

VANVERTS (*Gynéc. et Obstét.*, 1922, v, 4) discusses the indications for hysterectomy as deduced from the results of ennetting for infection following abortion. In cases of fever following abortion it is the writer's practice, provided that the signs of sepsis have persisted not longer than seven days, and that signs of extension of the infection to the peritoneal tissue are absent, to remove retained products of conception from the uterus either by "curettage" or (when this digital removal is impracticable) by ennetting. In 80 cases so treated the pyrexia disappeared or became diminished on the following day; of these deaths ensued in 2, purulent pelvic peritonitis necessitating colpotomy occurred in 3, and temporary recrudescence of the fever in 3. Of 17 cases in

which fever had not abated on the day following intervention 5 terminated fatally, and the mortality among patients in whom pyrexia did not diminish by the fourth day after the emptying of the uterus is given as 55 per cent. With regard to hysterectomy, the writer believes that it is logical to proceed according to the prognostic indications afforded by the results following curetting or "cureage." Not every case in which fever persists is suitable for hysterectomy; regard must be had to the patient's general condition, and especially to the occurrence of rigors, the failure of curettage to remove more than insignificant amounts of debris, or the absence of reaction consecutive to a subcutaneous injection of turpentine—all of which signs indicate a very grave prognosis, and may be taken to justify radical treatment in the absence of signs of local peritoneal infection. Douay and others have advised hysterectomy immediately following a curetting or "cureage" which has yielded few retained fragments; with regard to this, as well as to the indications for hysterectomy (as recommended by Faure and others) without trial of curettage in cases which appear from the first to be of extreme gravity, or in which curettage is contraindicated by signs of general peritonitis or of well-marked septicaemia, Vanverts reserves his opinion. Hysterectomy should be done by the vaginal method. In the non-operative treatment of these infections the writer attaches much importance to the provocation of a fixation abscess by subcutaneous turpentine injections.

561.

Myomectomy.

GOULLIQUOD (*Presse méd.*, February 25th, 1922) has collected from the literature records of 39 cases of pregnancy following myomectomy; 5 out of 6 persisted to term. About 8 per cent. of myomectomies are followed by pregnancy, or, according to recent reports, a somewhat higher proportion. Labour in the great majority of instances has been uncomplicated, but three cases of rupture of the uterus have been described. Specifying the indications, on grounds of pathological anatomy, for myomectomy, Goulliquod remarks that submucous myomata or interstitial myomata of the anterior or posterior wall are specially suitable; hysterectomy is preferable for submucous myomata, for which myomectomy is difficult and likely to be accompanied by haemorrhage or followed by sepsis. In referring to the scope of myomectomy with regard to marriage, pregnancy, and obstetrical past history, it is pointed out that for childless married myomatous patients myomectomy gives the best prospects of maternity. Myomectomy during pregnancy is not recommended; rather, expectant treatment—the writer sees in pregnancy a valuable curative, and the only prophylactic, treatment of myomata, and regards late marriage as determining in many instances myomatous transformation of the uterus. Goulliquod cites two instances of pregnancy following the marriage of girls in whom myomectomy had been performed after their betrothal, as well as a case of five healthy children being borne by a patient operated on by myomectomy at the age of 25. Myomectomy has no higher operative mortality than that of hysterectomy for myomata, and except in subjects approaching the menopause is preferable to radiotherapy. Radium treatment should be reserved for medium-sized myomata in unmarried or aged patients suffering from severe haemorrhage. In performing myomectomy the writer uses three series of sutures—the first closing the bed of the excised myoma, the second closing the uterine incision, and the third uniting the severed edges of the serous investment.

PATHOLOGY.

562.

The Pyramidon Test for Blood.

A. FORTWAENGLER (*Zentralbl. f. inn. Med.*, May 13th, 1922) confirms the discovery of Thévenon and Rolland (*Presse méd.*, 1918) and the researches of subsequent writers. He has proved that pyramidon is a much more delicate test for blood than either guaiacum or benzidine. The solutions required for the test are:

- (1) Pyramidon 5, alcohol (90 per cent.) 100.
- (2) Glacial acetic acid 25, distilled water to 50.
- (3) Hydrogen peroxide (Merck) 5 per cent.

The original method was as follows: To 2 to 3 c.cm. of the fluid to be examined were added 6 or 8 drops of the acetic acid solution, 2 c.cm. of pyramidon solution, and 6 or 8 drops of 5 per cent. hydrogen peroxide. The mixture was well shaken and allowed to stand. The appearance of a lilac colour is positive for blood. Fortwaengler has increased the acetic acid solution to 16 drops and the peroxide solution to 12 drops, and claims that this gives a more rapid and distinct coloration. He also recommends that after shaking up the suspected fluid with the acetic acid solution and allowing the mixture to stand for a time, the test tube should be

inclined and the hydrogen peroxide solution gently poured on the surface of the mixture: if blood be present a "lilac cloud" will appear very suddenly; if this is absent at the end of two minutes the specimen contains no blood. The writer has made exhaustive tests, and finds that while the guaiacum test is only positive in a 1 in 1,000 dilution of blood, pyramidon shows blood in 1 in 21,000 dilution; it is said to be equally reliable as a test for occult blood from any part of the alimentary canal. He also tested it with exogenous substances—namely, iron and bismuth salts and chlorophyll (in an ethereal extract of spinach); he found that pyramidon gave a negative result with all these substances. The usual technique for extraction of occult blood from stomach contents and faeces was employed.

563.

Soft Chancre.

TEAGUE and DEIBERT (*Journ. of Med. Research*, 1922, vol. xliii, No. 1) recommend the following technique as most suitable for the recognition and cultivation of Ducrey's bacillus, the organism of soft chancre. Small tubes of clotted rabbit blood are heated for five minutes at 55°C. or kept in the ice box for three to six days. The tubes are inoculated by transferring a bead of pus from the soft sore by means of a sterile wire and stirring it about in the serum around the clot, after which the tubes are sent to the laboratory and incubated for twenty-four hours. In smears from cultures stained by Gram's method a diagnosis can be made from the morphology and arrangement of the bacilli on the same principles as those governing the diagnosis of diphtheria. Stock cultures are best preserved by transferring the growth into clotted rabbit blood heated at 55°C. for fifteen minutes, incubating for twenty-four hours, and then keeping the cultures in the ice chest, where they remain alive for at least three weeks. Numerous irregularly shaped involution forms were obtained when the bacillus was grown in clotted rabbit blood heated for ten minutes at 64°C., and this procedure may serve as an aid in the identification of freshly isolated strains of Ducrey's bacillus, just as involution forms on salt agar are helpful in the diagnosis of *B. pestis*. The authors point out that the statement that Ducrey's bacillus is non-haemolytic is only true for the first forty-eight hours of growth on blood agar; on the third or fourth day a distinct zone of haemolysis appears around the colonies. A study of the cultural requirements for the growth of Ducrey's bacillus showed that for satisfactory growth on solid media it was necessary to have incorporated with the agar either a casein digest or peptone solution, plus rabbit serum and extract of red cells.

561.

The Cicatrization of Wounds.

EXPERIMENTS have been carried out by EBELING (*Journ. Exper. Med.*, May, 1922) with a view to determining the influence of temperature on the rate of cicatrization of wounds. Two young alligators were used. A rectangular flap of skin on the ventral surface of the body was resected and the outline of the wound traced with Indian ink upon a piece of cellophane placed over the surface. The tracings were transferred to paper and the areas measured with a planimeter. The animals were placed in a room having a temperature of 38°C. until the wounds had healed. Several days later a second resection of skin was made in a different area on the ventral surface of the body of each animal, as nearly as possible the same size as the first, and the animals were confined in a room at a temperature of 23°C. The time which each wound took to heal was carefully noted. After allowing for the very slight difference in sizes of the two wounds made, it was found that the rate of cicatrization was approximately doubled in velocity for a rise of 16°C. As this is equivalent to the increase in velocity which occurs in simple chemical reactions, it would seem probable that despite the complexity of the metabolic processes which take place in the animal organism the rate of cicatrization depends on the speed at which certain chemical changes occur in the process of healing.

565. The Presence of *Leptospira Icterohaemorrhagiae* in Rats.

FOLLOWING on a case of spirochaetosis which occurred at Montpellier, CARRIET (*Soc. Biologie*, May 13th, 1922) carried out a very limited investigation of the rats in the town, as a result of which they were able to detect one infected animal—*Mus decumanus*—amongst the first twenty examined. Similarly, DA SILVA, working in Lisbon in March of the present year, succeeded in detecting the infection in one rat out of the twelve which he examined. In both cases the technique adopted was that of subcutaneous or intraperitoneal inoculation of guinea-pigs with an emulsion of the kidneys, suprarenals, and liver of the suspected animal. If positive, the guinea-pig develops jaundice about the seventh or eighth day, and dies within the succeeding twenty-four hours.

A Nutrient Food containing

*Bone Marrow (12½%), Yeast Extract
and their associated accessory
factors (A. and B.), together with
Hæmoglobin and Malt Extract.*

Bynotone
(Trade Mark)

'Bynotone' is a combination of bone marrow, hæmoglobin, yeast nuclein and malt extract, and is put forward as a concentrated nutrient of wide applicability in the treatment of malnutrition in infants, adolescents and adults. It also provides a source of supply of accessory food factors which are necessary for normal metabolism particularly in infancy but also in adult life.

'Bynotone' is in the form of a granular powder and thus presents its various elements in a highly concentrated form. The preparation is not unduly hygroscopic and keeps perfectly if the container is well closed.

Where an Investment of £3,000—£4,000 yields an immediate return of £250—£500 a year—and an Annual Income of £1,500—£2,000 in the near future
—and Income Tax is only 1/- in the £.

A pleasant home and assured future for the settler—a chance to make the most of his capital for the investor.

Many of those who can find no attractive opening for their energies in the home country will find just what they want in a farm on the Harlen Estate, South Africa.

The estate possesses every natural advantage for apricot and general farming. It stands about 1,900 feet above sea level and the climate is all that could be desired both for the maintenance of human health and the conduct of profitable farming operations. The soil is rich and deep, and a thoroughly efficient irrigation system removes any risk from drought.

The position of the estate gives it further high claim to

consideration. It is situated on the bank of the Great Fish River at the junction of the Port Elizabeth—East London lines with the main railway route to Johannesburg.

The farmer has thus ready access to ports and markets where there is an unfailing demand for his produce. He has, moreover, the opportunity of being able to market his apricots, &c., for export when supplies from elsewhere are unobtainable.

Expert advice and assistance on the spot—entirely gratuitous—enable the settler successfully to solve every problem that may arise.

At small cost the investor who does not wish to become a resident can have his estate managed for him in the most competent manner.

An Address

ON THE

SINS AND SORROWS OF THE COLON.

DELIVERED BEFORE THE HARRGATE MEDICAL SOCIETY
ON NOVEMBER 26TH, 1921,

BY

ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,

PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

THE sins of the colon are its diseases. But I sometimes wonder whether it is not more sinned against than sinning, for what with attacks from above with purges, attacks from below with douches, and frontal attacks by the surgeon, its sorrows are numerous and real. I believe that a more thorough appreciation of its normal anatomy and physiology, and the routine employment of the various methods of examination, which modern science has made available, are wanted in order that its sins may be recognized at such an early stage that treatment may lead to their complete and permanent relief.

The Motor Functions of the Colon.

Like all other hollow organs, the motor functions of the colon depend upon tone and peristalsis, which are mutually independent. An atonic stomach or colon is often referred to as if it were one in which peristalsis was deficient, but peristalsis is often very active in the presence of hypotonus, and may be weak or irregular in the presence of hypertonus. The tone of the colon depends largely upon the bulk of its contents, and varies continuously according to the amount of faeces and gas present in each segment at the moment. Owing to this the internal pressure is normally constant and only rises when its tone or the volume of its contents is pathologically excessive, pain being then produced. As the caecum and ascending colon contain large quantities of semi-fluid faeces during the greater part of the day, their tone is less and their lumen is consequently much greater than that of the rest of the large intestine, especially the descending and iliac colon, which are generally empty and consequently in a state of tonic contraction, which more or less obliterates their lumen. Thus it is quite normal to find a large and splashy caecum, when the part of the colon which can be felt in the left iliac fossa feels like an almost solid cord.

Anybody who has made frequent x-ray examinations after a barium meal must have been struck by the remarkable contrast afforded by the continuous peristalsis of the stomach and continuous peristalsis and segmentation of the small intestine on the one hand, and the completely motionless colon on the other. On comparing the appearance of the colon every hour through the day, I was struck by the fact that it only changed materially after those hours in which a meal had been taken. By making a screen examination at intervals of a quarter of a minute during the latter part of a meal and immediately after we were rewarded by seeing on several occasions "mass peristalsis," which had already been described by Holzknecht, and is now recognized as being the only movement of importance which occurs in the colon. Two or three times a day a powerful peristaltic wave moves rapidly along a considerable length of the bowel, carrying all the contents before it. The chief stimulus to this movement is the gastro-colic reflex, which follows the entrance of food into the empty stomach. After all of the soluble material and most of the water have been absorbed from the intestinal contents, they are carried from the caecum and ascending colon by the mass peristalsis to the pelvic colon, where they remain until the first peristaltic wave of the following morning occurs, either as a result of the stimulus of getting up and dressing or of breakfast. They are then carried into the previously empty rectum, where they give rise to the desire to defaecate, which is followed by the normal reflex process of defaecation. Consequently during the greater part of the day the caecum, ascending colon, and pelvic colon are more or less full, but the rest of the colon is generally empty.

The Radiology of the Colon.

No attempt should be made to treat a case of constipation, which does not quickly respond to simple treatment, until an x-ray examination has been carried out. This should not be done until the patient has discontinued the use of aperients

for forty-eight hours, but, if necessary, an enema can be given the day before and again in the early morning of the day on which the examination begins.

By no other means is it possible to compare the position of the colon in the erect and horizontal postures, to determine whether adhesions are present, fixing its different segments to each other or to neighbouring structures, and to discover how quickly the intestinal contents traverse the bowel and how long their residue remains in each segment. It is, however, useless to carry out such an investigation unless the remarkable variations which may occur in normal individuals are thoroughly recognized. The times I gave in 1907 as the average rate for the passage of the intestinal contents in healthy individuals were nothing more than the average, though they have often been taken as the "normal" times, the slightest divergence from which has been regarded as pathological. Healthy individuals, however, vary within wide limits in this direction, and the position and mobility of the caecum, ascending and transverse colon are also subject to considerable variations. It is not pathological for the caecum to drop into the pelvis in the erect position, and a powerful forward in the Guy's fifteen of 1907, who had never had a day's indigestion or constipation, was only one of several perfectly healthy individuals I have seen with the greater curvature of the stomach over two inches below the umbilicus and the transverse colon reaching almost to the bottom of the pelvis.

Stasis of the colon hardly ever gives rise to symptoms by causing links, and stasis in the colon must be considerable before it can be regarded as of real importance.

It is an interesting fact that more than half of the severe cases of constipation which have been sent to me in the last fifteen years have suffered from pure dyschezia, or inefficient defaecation, the passage through the intestines having been normal in rate. In such cases the only treatment required is re-education of the act of defaecation by a proper attention to the hygiene of the bowels, together with the use of graduated glycerin enemas in resistant cases. In the remaining cases stasis in the proximal part of the colon was most common; it is comparatively rare for the whole of the large intestine to be involved. An accurate diagnosis will show what form of treatment by diet, drugs, massage (given on the first occasion under the x-ray screen so that the exact manipulation required can be observed), exercise, and, in the case of general colonic stasis, intestinal lavage is indicated in each individual case.

Radiography after an opaque meal rarely reveals the presence of a growth in the early stage; in all suspicious cases a barium enema should be given, as this is often arrested at the seat of the tumour, but I have seen a few patients in whom this method also failed to show anything abnormal, although a growth was discovered by other means, or subsequent events showed that one was present.

Colitis and "Colitis."

Colitis is inflammation of the colon. But the term "colitis" is very frequently applied in the absence of any evidence that the colon is inflamed. I am convinced that the loose employment of the word is an important factor in the development of many cases of severe hypochondriasis. Colitis should never be diagnosed unless positive evidence of its presence is obtained by examination of the stools and by means of the sigmoidoscope. Under normal conditions the mucous membrane of the colon is kept moist by the secretion of mucus, which renders the onward passages of the faeces more easy. Like all other mucous membranes, it reacts to mechanical and chemical irritation by the secretion of excess of mucus, in order to protect its delicate lining epithelium from injury. Consequently the presence of hard faeces in the normal colon calls forth a secretion of mucus. If the faeces accumulate in the rectum, the mucus is *unformed*. If, however, the mucus is produced in the pelvic colon or more proximal part of the large intestine, and a thin layer of mucus remains in contact with the mucous membrane sufficiently long, a ferment, mucinase, which is present in the mucous membrane, causes it to coagulate, much in the same way as fibrinogen forms fibrin when blood coagulates. A membrane of coagulated mucus is produced, and this is subsequently passed in the form of shreds, or occasionally tubular casts of the part of the colon in which it was produced. Microscopical examination of this mucus may demonstrate the presence of desquamated epithelial cells, but there are no pus cells or other evidence of inflammation, and the sigmoidoscope invariably shows that the mucous membrane is perfectly healthy. The name "mucous or mucous-membranous colitis" commonly applied to

his condition is therefore incorrect. When pain caused by spasm of the colon coexists, as it often does, the term "mucos-membranous colic" might be used, but in the absence of pain the condition should not be regarded as any more pathological than the presence of a little unformed mucus with scybala which have been retained rather longer than usual in the rectum.

When mucus is present with soft or fluid faeces colitis is more likely to be present. But inquiry must first be made as to whether an aperient has been taken, because the mucous membrane also protects itself from the chemical irritation of drugs by the production of mucus. Thus the existence of colitis can only be inferred from the discovery of mucus if the faeces are unformed and no aperient has been taken.

More important than mucus is the presence of pus in the stools. This always indicates that some organic pathological condition exists. In cancer and in ulcerative colitis the pus can generally be recognized by the naked eye. If, however, it comes from the more proximal parts of the colon, it is likely to be intimately mixed with the faeces and the mucus, both of which should be examined microscopically, especially if the latter is unformed and opaque instead of transparent.

In the absence of haemorrhoids bright red blood in the stools is of equal significance. If no mucus or pus is present it probably comes from a rectal polypus, but if mucus and pus coexist acute haemorrhagic colitis, ulcerative colitis, dysentery, or cancer is almost certainly present.

Unless abdominal or digital examination of the rectum reveals the presence of a growth with certainty, a sigmoidoscopic examination should be made in every case in which the symptoms and the appearance of the stools suggest the presence of colitis or a growth.

The Sigmoidoscope.

The sigmoidoscope is one of the most valuable of all instruments used in the investigation of disease, and yet it is rarely employed except by surgeons, especially those interested in diseases of the rectum. In my opinion every physician and every practitioner should familiarize himself with the sigmoidoscope. With a little practice it can be introduced with perfect safety into the bowel of women as well as men without an anaesthetic and without causing anything more than a moderate degree of discomfort. An anaesthetic makes it impossible to assume the knee-elbow position, in which the passage round the pelvi-rectal flexure can be negotiated in almost every case without inflation, which is a matter of great importance, as inflation not only causes pain, but may also be dangerous when the wall of the colon has become thinned by ulceration.

It is no more justifiable to treat colitis without first inspecting the mucous membrane of the colon with the sigmoidoscope than it is to treat a sore throat without looking at the pharynx. I have seen numerous cases, which had been treated for months as "colitis," in which the sigmoidoscope revealed the presence of a growth. It must be remembered that the pelvi-rectal flexure, the most common place in the colon for the development of cancer with the exception of the rectum, is beyond the reach of the finger introduced per anum, and a growth here and in the lower six inches of the pelvic colon, which are also accessible to inspection with the sigmoidoscope, is often impalpable from the abdomen, although it can sometimes be felt through the front wall of the rectum or by bimanual examination.

With the sigmoidoscope, too, the various forms of colitis can be recognized, the absence of any inflammation in mucos-membranous "colitis" can be demonstrated, the diagnosis between amoebic and bacillary dysentery can be made, and the process of recovery in colitis and dysentery can be watched. The symptoms of ulcerative colitis and dysentery, like those of gastric and duodenal ulcer, disappear under treatment long before the ulcers are healed. We have the great advantage in treating the former that the sigmoidoscope makes it possible to determine when the cure is really complete, and no case should be allowed to pass from active treatment until the sigmoidoscope has demonstrated that the mucous membrane is perfectly healthy. By this means alone the disappointing relapses can be prevented. Only when the sigmoidoscope comes into its own will the surgeon see most cases of cancer of the pelvic colon and upper part of the rectum at the early stage, in which alone a radical cure by operation is still possible.

The Use and Abuse of Purgatives.

If the fortunes made from purgative pills had been devoted to the hospitals which treat the victims of their abuse, the financial problem of the voluntary hospitals would have been solved. About £10,000,000 was expended in 1921 on patent medicines, the majority of which contain purgatives.

I have already pointed out that the stools should be inspected and the x-ray examination carried out whilst no aperient is being taken. It is interesting to observe how large a proportion of patients, who are supposed to be the victims of toxæmia from intestinal stasis, feel better whilst these examinations are being carried out. The fact is that symptoms result far more frequently from the artificial diarrhoea produced by purgatives than from intestinal stasis. Purgatives often cause abdominal pain, intestinal stasis very rarely. Bacterial decomposition is very active and excess of toxins is produced and absorbed in the colon when its contents are kept fluid by the use of purgatives, but the reverse is the case in the semisolid or solid contents of the colon in intestinal stasis.

On several occasions when I have been asked to decide whether the operation of colectomy, which had been recommended for "intestinal stasis," should be performed, I have found that all the symptoms disappeared on giving up purgatives and adopting some more rational treatment. It is sad that the description Gulliver gave the Houghnubms of the habits of his fellow countrymen is as true to-day as it was in 1727: "They take in at the orifice above a medicine, equally annoying and disgusting to the bowels, which relaxing the belly drives down all before it; and this they call a *purge*." I do not say that an aperient should never be used, but when required, one should be chosen and a dose should be found which result in the passage of a single formed stool each morning.

Intestinal Lavage.

The mythical origin of intestinal lavage should be of interest in Harrogate, where many thousand Plombières douches are administered every year. Pliny (A.D. 77) tells how the Egyptians learnt to wash out their bowels from observing the habits of the ibis: "He washes the inside of his body by introducing water with his beak into the channel, by which our health demands that the residue of our food should leave." It is cruel to deprive the ibis of his elaim to this epoch-making discovery, but the truth must be told: the ibis does not give himself a Plombières douche, but after washing his beak in water he oils it in his pre-cloacal gland, which is situated near the anus, in preparation for preening his feathers.

In the seventeenth century the enema reached the height of its popularity. It is recorded that Louis XIV received several thousand intestinal douches in the course of his life, and that the pious Duchess of Alva treated her sorely ill son with enemata of an emulsion of religious relics. Unhappily they failed to save him.

The last twenty years have seen a remarkable revival in the popularity of the intestinal douche, a popularity which has led at times to its indiscriminate use for conditions in which it was not suitable. It is a valuable remedy, but its precise indications require to be defined, and I should like to say a few words about the technique of its administration.

In the first place intestinal lavage is of use when it is necessary to remove retained faeces from a colon which, on account of its irritable or inflamed condition, ought not to be further irritated by the use of aperients. Mucos-membranous "colitis" comes under this category. The fluid used should be of a non-irritating character, or a condition of catarrhal colitis will be added to the hypertonic and hypersecretory condition already present, just as the inhalation of irritant fumes produced by the burning of the powders used in asthma causes catarrhal bronchitis to be added to the simple hypertonic and hypersecretory condition of the bronchi, which is alone found in uncomplicated asthma. I had thought at one time that the Harrogate sulphur water used for intestinal lavage might sometimes act as such an irritant, but I have found by actual experiment on the healthy mucous membrane of the colon that it is no more irritating than normal saline solution. It would be interesting to know whether it owes to its radio-active or other constituents any healing properties not possessed by the latter. There is a real danger that a course of intestinal lavage in cases of this kind might lead to constipation by making the patient too dependent upon them.

For this reason patients should attempt to get their bowels open naturally each morning before they receive their douches; if this is impossible they should have paraffin, together, when necessary, with the minimal dose of senna required to produce a stool.

Secondly, intestinal lavage is of great value in the treatment of the severer forms of colitis, and especially of ulcerative colitis. Antiseptic and astringent drugs can be applied by this means directly to the mucous membrane in any required strength, without becoming diluted in the stomach and small intestines and without irritating them. The drug I have found most valuable in the local treatment of colitis is albarguin, a silver nucleinate, which Rogers proved experimentally was the most satisfactory antiseptic in cases of dysentery. A solution of 1 grain to 1 ounce of water should be used.

It is of great importance that the douche should be properly administered. Nurses are always taught to pass the tube as far into the rectum as possible, and they are rarely satisfied unless twelve or more inches have been introduced. Until comparatively recently I understand that this was the practice not only in Plombières, but also in Harrogate and the other English spas in which the treatment has been employed. But the pelvi-rectal flexure, where the freely movable pelvic colon joins the fixed rectum at an acute angle, is four and a half inches from the anus, and it is a physical impossibility to pass a rubber tube beyond the flexure, except through a sigmoidoscope which has been manipulated through the flexure. This was proved long ago by Sir James Goodhart in the post-mortem room, and in 1908, and again more recently, I demonstrated the same fact with the x rays, which show that the tube turns back when the flexure is reached, and then curls up in the rectum. The end of a tube passed in the usual way must therefore rub against the mucous membrane of the rectum, and when twelve or more inches of stiff tubing are introduced into the rectum it is obvious that a considerable amount of damage may be done. This explains the observation I have frequently made, that in cases of severe colitis treated by douching through a tube introduced in the ordinary manner, the sigmoidoscope shows a pelvic colon either healed or nearly healed, whereas the whole of the rectum, which has been rubbed every day with the tube, is still acutely inflamed. The tube should therefore be introduced not more than two inches beyond the anus. The fluid should be run in slowly at a pressure not exceeding twelve inches of water, and not more than a pint and a half should be used. The x rays have shown that a barium enema of a pint and a half of fluid, introduced at a pressure of twelve inches, through a tube inserted two inches beyond the anus, invariably reaches the caecum, whatever position is assumed by the patient, unless organic obstruction is present. I believe that de Graaf was correct when he wrote in his monograph, *de Clysteribus*, in 1668, that the usual ritual of lying in a series of positions during the administration of the douche has not the slightest effect. There is no doubt, however, that the knee-elbow position, by making the pelvi-rectal flexure less acute, allows the fluid to pass more readily into the pelvic colon and so prevents the overdistension of the rectum, which otherwise may make it difficult for the patient to retain the fluid for twenty or thirty minutes, as is advisable in the severe forms of colitis.

The Surgery of the Colon.

Apart from the treatment of cancer of the colon, diverticulitis, and other causes of acute and chronic obstruction, the indications for surgery in diseases of the colon are few. At one time I believed that appendicostomy or caecostomy should be performed in every case of ulcerative colitis of any severity, as Lockhart-Mummery has so persistently urged. But since I discovered that anti-dysenteric serum has such a remarkable healing effect on the disease, I believe that it will in the future only be necessary to perform the operation in the exceptional cases in which no improvement follows the intravenous injection of large doses of serum.

I have always held that intestinal stasis only required surgical interference in very rare and neglected cases, in which prolonged medical treatment fails to relieve local and general symptoms of real severity. In the fifteen years I have been interested in the subject I have only recommended five patients to undergo an operation for this condition—three times short-circuiting and twice partial colectomy. One patient died, one was completely and per-

manently cured, and the remaining three were benefited to a varying extent. Short-circuiting of the part shown by the x rays to be affected, without dividing the bowel, or its excision should be performed in preference to complete colectomy. The statistics of Guy's Hospital show that the mortality in total colectomy for intestinal stasis is about 16.5 per cent. The ultimate results of the operation would require to be extremely good to justify such a high mortality, considering that with the exception of one case recorded by Lockhart-Mummery² intestinal stasis has never, so far as I know, proved fatal. I have come across an occasional brilliant result, but improvement is much more frequently only partial, and in many cases the patient is either no better or is actually worse than he was before the operation. It is a surgical aphorism that no operation should be performed on the stomach in the absence of a demonstrable lesion, and I look forward to the time when a similar aphorism will be applied to the colon. I have been appalled in the past to see how lightheartedly colectomy has been recommended for comparatively trivial symptoms before any serious effort has been made to treat them by other means. But it is satisfactory to note that the operation, which reached the height of its popularity shortly before the war, is gradually becoming obsolete. I was told in 1919 during my visit to Cleveland, Baltimore, and the Mayo clinic, that, after an unsatisfactory trial, colectomy was now no longer practised for intestinal stasis, and in contrast to the forty colectomies performed at Guy's in 1914 only one was performed in 1920 and not one in 1921.

A Diagnostic Clinic for Harrogate.

I have endeavoured to show how the treatment of diseases of the colon should never be undertaken before a thorough investigation has been carried out. I have not referred to various other examinations of equal importance—such, for example, as that of the secretory functions of the stomach by a fractional test meal, which may reveal the presence of achlorhydria, one of the most common causes of chronic diarrhoea, and a powerful predisposing factor to infection of the bowel.

These investigations require team-work. Each physician practising in a health resort like Harrogate should have at his disposal a diagnostic clinic, into which his patients could be admitted for ten days or a fortnight whilst he investigates them by the usual clinical methods, inspects their stools, and, when necessary, makes sigmoidoscopic examinations, whilst his radiological, biochemical, and bacteriological colleagues carry out such examinations as he may direct. At the end of this period he will be in a position to advise what treatment is required during the remainder of the patient's visit.

If possible the physicians should have no financial interest in the nursing-home side of the clinic. Patients should receive two accounts, one from the clinic and one from the physician. The latter should be an inclusive one, fixed beforehand, which should cover every examination which may be required. A certain proportion of the physician's fee should be paid to a central fund, out of which the radiographer and pathologists receive their salaries, which would thus be proportionate to the amount of work they are called upon to perform.

During the past year I have been associated with a clinic run on somewhat similar lines. Investigations have been carried out by clinicians, pathologists, and a radiographer, working as a team, and I can assure you that my work has been more interesting, less fatiguing, and more satisfactory from my own and from my patients' point of view than it ever was before. I believe that the future of medicine lies largely in the development of team-work in diagnostic and treatment clinics. In this direction Harrogate has a great opportunity. It should lead the way in establishing spa treatment on a sound scientific basis, so that those earlier days will sink into oblivion when spa treatment meant the application of spa water to the skin, the stomach, and the bowel, whatever was the matter with the patient, and Guy Patin's criticism of mineral waters, "I do not believe much in these, they never cured anybody, and I never believed that they would," was justified. Harrogate will then maintain its position as the Mecca for the sins of the colon, and will be free from any suspicion of reproach as adding to its sorrows.

A PHYSIOLOGICAL EXPLANATION OF PAIN DUE TO FUNCTIONAL DISTURBANCE OF THE MUSCLES OF THE COLON.

BY

T. STACEY WILSON, M.D., F.R.C.P.,

HONORARY CONSULTING PHYSICIAN, BIRMINGHAM GENERAL HOSPITAL.

It has long been known that the colon is liable to a functional disturbance of its muscular coat which consists in such a hardening of its walls as to render the outline of the bowel sufficiently distinct to suggest its forcible distension with gas. This theory, however, as to the cause of the hardening is not admissible because palpation of the colon shows that the character of the hardening and its distribution could not be explained by distension with gas, and the phenomenon must be due to some peculiar activity of the muscular coat of the bowel. This hardening is associated with pain and usually with tenderness of the hardened portions of the colon. This abnormal rigidity of the colon constitutes one of the common physical signs of the complaint known as "mucous colitis." It also occurs in the caecum in cases of appendicitis, and the tumour felt in this condition is sometimes mainly due to this cause. It may, however, occasionally occur apart from all other symptoms of disturbance of the colon, not even constipation being present.

The clinical aspects of this peculiar state of the colon wall was discussed in the International Medical Congress which was held in Paris in the year 1890. It first came under my notice in 1892, when I had a patient in whom the whole of the ascending colon from the iliac fossa to the hepatic flexure could be felt as a tube with rigid walls nearly the diameter of a woman's wrist. The case was supposed to be one of appendicitis, and the patient had had many similar attacks prior to my seeing him. The colon retained this remarkable rigidity for some days; it passed off gradually from above downwards, and when the muscular spasm had apparently ceased the hardening could, nevertheless, be sometimes felt to return for half a minute or so under the hand during palpation, the bowel rising up and forming a hard tumour the size of a small hen's egg and then softening again. It was quite clear to me that this extraordinary case demonstrated the existence of a form of muscular activity in the bowel wall which was not generally recognized, and the muscular hardening which was palpable in the colon appeared to me to be strong confirmation of the theory advanced by the late Professor Rutherford of Edinburgh that muscular fibres had not only the power of contraction but also of an extension which was a vital act on the part of the muscular tissue.

A study of this and many similar cases which have come under my notice since has been sufficient to convince me that the muscular fibres of the circular coat of the colon have the power of becoming rigid in an extended condition and of thus turning the colon into a tube with rigid walls and a definite lumen whose diameter varies in different cases and sometimes is as much as 1½ inches or more.

I have palpated the colon in the right and left iliac fossae in practically every patient I have examined during the last thirty years, and this careful examination of the muscular tone of this part of the intestine has abundantly confirmed the opinion I formed in 1892 that muscular fibres must have the power of becoming rigid in an extended condition. Until quite recently the accepted teachings of physiology have given no help whatever to the clinician so far as any explanation of this phenomenon is concerned. In the year 1915, however, Professor Sherrington contributed an important paper to *Brain* which gives an entirely satisfactory explanation of the muscular hardening which is clinically observable in the colon.

Postural Activity of Muscular Fibres.

In this paper Professor Sherrington shows that muscular fibres, in addition to the power of contraction, have another form of activity to which he applies the term "postural activity," because it plays so important a part in maintaining the posture of the body. This form of activity might be mistaken for a true tonus, but he shows that if voluntary contraction be eliminated (by removal of the cerebrum of an animal, such as a cat) the muscles are capable of exerting considerable force without any definite contractile activity. For instance, if a limb be supporting a weight, the removal of the weight will not cause any material movement of the limb, as would have been the case if the weight were being

supported by contractile activity. It seems as if a muscular fibre had the power of becoming rigid in any condition of extension or contraction and of retaining this attitude for a long period of time, or, on the other hand, of varying it as necessary under nervous control. In the case of the bladder he draws attention to the fact that an almost empty bladder can be gradually distended with almost no alteration of the intravesical pressure, the muscles, while retaining the same grip upon the contents, gradually lengthening, so as to enlarge the size of the bladder.

He kindly gave me the bearing of his observations upon the question here discussed. He says:

"In their postural or tonic activity the tension of muscles or muscle fibres is largely independent of their length. Therefore a ring-muscle, for example, in the gut, may quite well assume a 'cartilaginous' hardness and yet maintain a ring-shape of any desired lumen—or if requisite might presumably obliterate its lumen. The case of the gut is quite analogous to the bladder or stomach; the musculature of these latter will exert no more pressure upon 200 c.cm. of content than on 50 c.cm. They grasp their content with the same pressure independently of the length of the muscular fibres, just as the hand can grasp an orange with the same light pressure as a walnut."

He also uses the following simile:

"Perhaps I can put the notion briefly by comparing the muscle fibre to a plaster-of-Paris brick, which would set and unset at the desire of a nerve. If a 6 inch brick were desired it flowed into a 6 inch length and there set; if a 3 inch, then it unset from the 6 inch length, became 3 inches shorter and proportionately wider, and set again. If a 9 inch brick, conversely."

In these observations of Professor Sherrington we have a perfectly satisfactory explanation of the hardening of the colon with which we are clinically familiar. We may not yet be quite certain as to the relationship between the postural activities of the colon muscles and their contractile functions, but this point is, I think, immaterial to the present argument. In the normal bowel there must be perfect co-ordination of these two types of muscular activity, otherwise a conflict between them would result. In the cases of which we are now speaking we recognize the occurrence of lack of co-ordination in consequence of an abnormal amount of postural activity interfering with the normal peristaltic contractions.

Possibility of Pain Arising in the Colon.

In such a case as this the stronger of the two types of muscular activity will overpower the weaker—an occurrence which, in the case of voluntary muscles, would be certain to give rise to pain, and the degree of pain would be proportional to the force of the opposing types of muscular activity.

In the case of the colon there is good clinical reason to believe that abnormal muscular activity of this nature is capable of giving rise to a true sensation of pain. When speaking, however, of the sensation of pain being caused by muscular conflict in the colon, we have to remember that it is devoid of nerves of common sensation, and therefore theoretically might be expected to be incapable of originating a sensation of pain. Before going farther into this question some physiological points must be considered in connexion with the relationship of the normal activities of the colon to the central nervous system.

The colon muscles are in touch with the brain through the sympathetic nervous system, and its muscular and secretory functions and blood supply are regulated by afferent and efferent impulses passing along sympathetic nerve fibres. Now muscular activities in the colon as elsewhere call for increased blood supply to the muscles concerned, and we know that increased blood supply to the splanchnic area (such as that which takes place during digestion) is associated with a certain amount of vaso-constriction of the cerebral vessels and of the arterioles of the systemic circulation. We have all experienced the mental and physical inertia which is apt to follow a full meal. We may therefore say that muscular activity in the colon (as in other parts of the alimentary tract) will give rise to certain afferent impulses which have the effect of causing relative vaso-constriction of the cerebral vessels, and which also are inhibitory to the systemic circulation.

When there is excess of postural activity the increased rigidity of the muscular wall of the colon which results from it must call for abnormally powerful contractile efforts for the accomplishment of peristalsis, quite apart from the possibility of a kind of muscular conflict taking place between the two opposed types of activity. This abnormal activity must originate abnormally powerful afferent impulses in the sympathetic nerves of the colon, and in so far as reflex

circulatory phenomena are concerned we must expect as a consequence an abnormal amount of inhibition of the cerebral circulation and also of that in the systemic muscles.

Therefore, if we take a series of patients who all show by increased hardness and by tenderness of the colon (in situations where it is palpable) that there is an abnormal amount of postural activity of its muscles we may reasonably expect them to show symptoms referable to inhibition of the normal vaso-dilatation which accompanies cerebral activity, and also of the normal vaso-dilatation in the muscles which accompanies physical exertion. In such a series of patients we do find many who show such symptoms as these. They will use some such expression as the following: "I do not know what has come over me, I seem to be losing my energy. When I sit down to write a letter or do a bit of brain work, instead of doing it as easily as usual I frequently find that I have to force myself to do it." They will speak of "brain weariness" and "mental inertia," and other symptoms suggestive of inhibition of the normal vaso-dilatation. That this is the true explanation, and that they are not suffering from ordinary neurasthenia, is shown by the fact that when by abnormal effort they have started to work (in other words, have accomplished normal cerebral vaso-dilatation) they work as easily as normal, and do not suffer from the exhaustion after the work is done which is so characteristic of a true neurasthenic state.

We also sometimes find in these patients who show excess of postural activity of the colon muscles that there are symptoms suggestive of inhibition of the vaso-dilatation which normally accompanies muscular exertion, and they will speak of lassitude and a sense of weariness, which, however, is not true exhaustion, because it will speedily pass off after a little brisk exercise. These symptoms are not usually continuous, but are more apt to come on intermittently, and are most liable to occur at times when the colon is functionally active. The early hours of the morning is apparently a time when the colon might be expected to be active in those patients in whom a morning evacuation of the bowels takes place. It is very common to find that such patients, when suffering from this functional colon disturbance, are apt to wake up of a morning (whether earlier or later) with very considerable mental depression, and when the time comes for getting up they are apt to feel distinct lassitude on muscular exertion instead of the normal absence of weariness after a night's rest. This lassitude, however, will pass off as soon as a little active exertion is undertaken, showing that it was merely of a vascular inhibitory nature, and not a true weariness.

The following is a very characteristic case where a sudden attack of mental depression would come on under circumstances which suggested that it had some reflex nervous origin, and was not a spontaneous mental phenomenon.

The subject was a dentist who came under my care for colon disturbance and whose mental troubles lessened as his colon condition improved and who has now for many years been quite free from them. I will quote his own description of the sort of attacks to which he was liable. He said: "I am sometimes enjoying a game of draughts with my wife on an evening after supper when suddenly a black cloud seems to come over me. My wife is unkind to me, my children are wicked, my practice is going to the dogs, and I am in the depths of misery till I can go to bed and sleep it off, as I can do." This same patient was liable to sudden attacks of mental depression with a suicidal tendency, so much so that when at the seaside he would not take a steamer trip unless he had some friend with him who promised never to leave him for an instant. Although happy as a rule, he felt that a sudden and uncontrollable attack of mental misery might overtake him at any minute just as a sudden attack of abdominal pain might do.

Returning to the question of pain in connexion with this functional muscular disturbance of the colon, it will readily be granted that if a muscular conflict does occur in the colon, such as has been described, the afferent impulses which would arise in the muscles concerned would be capable of causing a sensation of pain if the messages reached the sensory tracts of the cord. Now in the cases of which we are speaking pain is of frequent occurrence and of varying severity, and its clinical features are such as to confirm the theory that its causation must be the same as that of the reflex nervous symptoms of which we have spoken. For instance, as a rule the severity of the pain varies according to the amount of abnormal postural hardening (as judged by palpation) which is present in the colon. Also the pain is liable to occur at times of functional activity of the colon, just as the reflex symptoms do. Moreover, not infrequently it can be noticed

that the two sets of symptoms alternate in the same patient. The following is such a case.

A patient came complaining of indigestion and abdominal pain. He said, "I sometimes have pain in my abdomen, and I sometimes have attacks of mental depression, and it is a strange thing that when I am free from pain I have much mental depression, but when I have pain in my abdomen I am free from mental depression, and am happy. I cannot understand it—it ought to be the other way round; I ought to be happy when I am free from pain and depressed when I have got it, but I am not." In this case, when the nervous impulses were transferred from the sympathetic to the sensory tracts of the cord he felt pain; when they travelled to the brain along sympathetic paths he felt mental discomfort in place of pain.

In this connexion it is of interest to note that it is occasionally possible to substitute a sensation of pain for one of mental depression by intentionally inducing pain in a tender portion of the colon. By this means the afferent impulses which formerly were finding their way to some other part of the brain, and were causing mental misery, appear to be deflected to the sensory tracts and a sensation of pain takes the place of mental discomfort. I have on one occasion myself been able to experience this transference, and I sometimes find patients who can succeed in doing so after the possibility of the success of such an attempt has been pointed out to them.

The clinical study of these cases seems therefore clearly to demonstrate that pain can be caused by the transference to the sensory tracts of the cord of afferent impulses which arose in the sympathetic system and which if retained in that system would have caused disturbance of the brain of a reflex character and would not have caused physical pain. It seems probable that when the muscular activity which originates the nervous impulse is decidedly more powerful than those due to normal digestive activity there is considerable probability of this transference taking place, and where, as in cases approaching the severity of ordinary colic, the afferent impulse is an extremely powerful one the transference of the nervous impulse from the sympathetic system to the sensory tracts of the cord almost invariably takes place and a sensation of pain is the result. With regard to the localization of the pain it is not as a rule felt over the spot where it probably arose, but is usually "referred" or "segmental" in character.

Mental Misery of Colon Origin.

The clinical study of a series of cases where mental depression and neurasthenic symptoms result from functional disturbance of the colon muscles shows that there are some cases which cannot be explained by the theory of inhibited cerebral vaso-dilatation which has already been discussed. Where the circulation alone is concerned we have pointed out that the defect can be removed by a more vigorous mental effort, just as is the case with physical lassitude which can be overcome by a more vigorous muscular effort. It is not at all unusual, however, to find cases of functional colon disturbance where the mental depression is so severe as to be wholly beyond the patient's voluntary control, and constitutes an acute mental misery which is comparable in the mental sphere to a severe physical pain in the sphere of sensation. The occurrence of such cases compels recognition of the fact that nervous impulses arising in the colon and passing to the brain along sympathetic nerve paths have the power of directly disturbing that portion (or those functions) of the brain upon which the sense of wellbeing is dependent, and of giving rise to an acute mental misery which truly represents the physical pain which they would have felt if the afferent impulses causing it had been transferred from the sympathetic to the sensory tracts of the cord. It is my custom to tell such patients that they are feeling stomach-ache in their minds instead of in their bodies.

The fact that these cases are really due to the functional disturbance in the colon is demonstrable clinically by the fact that they yield to treatment which lessens the amount of postural activity in the colon. Patients have told me that the mental cloud of which they complained began to lift within a couple of days of commencing treatment for the colon trouble.

I have said nothing as to some less usual but very striking cases of reflex disturbance due to functional colon disturbance. I have seen two cases where the reflex contraction of the systemic arterioles was sufficient to cause attacks of vasomotor angina pectoris. I have seen cases with symptoms suggestive of Raynaud's disease yield speedily to

colon treatment. I have dealt successfully with cases of reflex weeping, of reflex screaming, and of reflex asthma and other interesting cases, which were clearly due to nervous disturbances arising in the colon. These varied cases have certain features in common. They are associated with colon hardness and tenderness. Symptoms are most likely to come on during periods of functional activity of the colon or when muscular activity in the colon is liable to be started by mechanical vibration. Moreover they are cured, and often speedily, by treatment which lessens the abnormal muscular activity of the colon.

In confirmation of what has been said as to the three chief ways in which the abnormal muscular activity of the colon affects the nervous system, it would be easy for me (as soon as time is available for analysing the material at my disposal) to select, from the hundreds of cases which I have treated during the last thirty years, three parallel series of cases where the condition of the colon, the mode of occurrence of the symptoms, and the results of treatment exactly corresponded, but where in the one series the symptom complained of would be pain, in the second evidences of reflex circulatory disturbance, and in the third series mental depression or mental misery (unaccompanied by any pain) would be the only symptoms complained of, except possibly constipation.

I hope that the further study of this subject will show that these theories regarding pain which I have brought forward have a solid foundation in fact, and that a more general recognition of the part which is played by functional muscular disturbance of the colon in cases which are apparently pure neurasthenia or causeless mental depression may greatly lessen the amount of suffering now being borne by these unfortunate individuals.

TWO HUNDRED AND TWENTY-FIVE CASES OF PNEUMONIA: AN ANALYSIS.

BY

AMBROSE W. OWEN, M.D., B.S. LOND.,

HONORARY SURGEON, ABERDARE AND DISTRICT GENERAL HOSPITAL.

SINCE October, 1917, I have attended 225 cases of pneumonia. I have excluded four patients, aged respectively 72, 70, 66, and 66, in whom pulmonary congestion was a contributory but not the main cause of death. I have tabulated the others etiologically as follows:

	No. of Cases.	Male.	Female.	Deaths.	Male.	Female.	Mortality per cent.
Lobar pneumonia	31	26	8	3	3	0	8.8
Bronchopneumonia:							
Primary and secondary to bronchitis	68	43	25	10	9	1	14.7
Secondary to measles and German measles	30	19	11	6	3	3	20.0
Secondary to pertussis	15	7	8	5	3	2	33.3
Secondary to pertussis plus measles	4	2	2	1	0	1	25.0
Secondary to acute gastro-enteritis..	1	0	1	1	0	1	100.0
Secondary to malaria	1	1	—	—	—	—	—
Influenzal (140) cases of influenza...	72	38	34	6	2	4	8.3
Totals	225	136	89	32	20	12	14.2

The mortality for the series is 14.2 per cent. The youngest case was aged 3 weeks, the oldest 83 years; both recovered. Diphtheria and scarlatina do not figure in the list, and out of several hundred cases of the two diseases (endemic here) I have not seen one in which pneumonia occurred. Doubtless the mild nature of the cases as compared with former days accounts for this. I have included in the list only undoubted cases of pneumonia. Cases marked in my visiting books "pneumonia, capillary bronchitis, etc." have been omitted, as have also many cases of prolonged influenzal pyrexia quite possibly pneumonic in nature, so that I have under- rather than over-estimated the total number of cases.

I make no claim to absolute scientific accuracy in the table, but as I have made a practice of taking notes of all cases of pneumonia I have a vivid recollection of all the cases

and think I am fairly correct. Probably the cases of primary bronchopneumonias are over-estimated and those of influenza under-estimated. A large number of the cases occur in infants and young children, and unless occurring in the influenza seasons, or in houses where adult members are ill with influenza, the differential diagnosis at the lower ages must needs be very difficult.

All the patients were of the industrial class, living for the most part (five were in hospital) in overcrowded, not always overclean, houses, and had as nurse, as a rule, a harassed female already preoccupied with the needs of a large number of children. The mortality, in spite of this, seems to compare favourably with that of hospital statistics. Is it because only the worst cases are sent to hospital, or is it the journey thither?

Recurrences were noted in twelve patients, each having two attacks. I have excluded in this connexion three patients now in a state of chronic bronchopneumonia; I have credited each with one attack, their condition never having resolved. They are liable to attacks of febricula—all, in fact, have withstood influenza, and were I not cognizant of their condition I should have labelled them all influenzal pneumonia, on account of the physical signs.

A study of the cases shows that pneumonia, especially in the fatal cases, is often a disease of ill health. With the exception of the cases under one year, after the infectious diseases (and even in them a certain amount of contributory ill health can often be demonstrated) the possession of a clean bill of health is of paramount importance in the prognosis. I have little fear of pneumonia in a young, undoubtedly healthy adult. This is, of course, well recognized by all physicians, as witness the old German army statistics, mentioned by Osler, in which the death rate among 40,000 picked men was only 3.6 per cent.

Previous Morbidity of Cases.

Of my non-fatal cases phthisis definitely existed in 4. It was diagnosed (before the pneumonia) by a tuberculosis physician in 2 (I was doubtful—both now in good health); 2 were marked "? T.B. element"—both had attended previously at a tuberculosis centre; one was marked "stromous child—liable phlyctenular conjunctivitis"; one "scars neck after T.B. glands"; one "one brother phthisis, other T.B. elbow"; and one occurred in a young boy admitted to hospital for operation for "? chronic appendix or T.B. peritonitis." He developed pneumonia whilst waiting operation, which was postponed until he got stronger, and has not yet been performed. These make 12 tuberculous, or strongly suspected tuberculous, patients; 3 were recent syphilitics, well beyond the secondary stage—that is, the pneumonia was not due to the syphilis. Chronic bronchitis existed in 5, and gouty bronchitis in one. An attack of subacute rheumatism (old undoubted case of rheumatism) was followed by pneumonia in one; he was removed to hospital for treatment of the rheumatism on a cold day, and the pneumonia was due, I thought, to the removal and not to the rheumatism. One man had aortic incompetence—also old rheumatic. One infant was a congenital syphilitic baby and one rickety. Two adults were chronic alcoholics; and one boy, aged 16, a congenital idiot. These make 28 morbid cases, and to these must be added 3 (recurrence took place in 3 of the 28), which make 31 morbid cases out of 193—a percentage of 16.

Fatal Cases.

Two of these were of very tender age—one 6 weeks, the other (a twin) 11 weeks; both followed pertussis. Of the morbid conditions, one, aged 4 months, was a premature (eight months) baby; two, aged 10 and 11 months (former a twin), had "severe anaemia"; one, aged 11 months, was a congenital syphilitic, marasmic baby; one, aged 2½ years, was a paraplegic child who had been so for three months after an attack of myelitis (not poliomyelitis), which I attributed to influenza; one, aged 26, was a dwarf with chronic bronchitis and emphysema; and one, aged 53, was a chronic asthmatic. Phthisis also played a prominent part here; 3 were definitely phthisical: the ages were 32, 25, and 4½ years. The two latter were mother and daughter, and all three were victims of the November, 1918, influenza epidemic. I might mention here that 5 out of the 6 influenza deaths were in "morbid" patients. In 3 cases phthisis was strongly suspected before the pneumonia: No. 1, aged 34 (since his death his wife and a daughter, the latter one of this series, are dead of phthisis); No. 2, aged 3½ years, lasted for three months after pneumonia following measles plus pertussis, and

died of phthisis—a sister had died previously of tuberculous meningitis; No. 3, aged 16 months (his only brother had died of phthisis a year previously). Thus 13 out of 32 were "morbid" cases—that is, 40.6 per cent. These figures represent the apparent morbidity; as will be seen later, in one or two cases morbidity probably existed but was not suspected. These facts are more usefully expressed in the following table, which gives also the age incidence of all the cases. It will be seen that 50 per cent. of the deaths were in infants under 1 year, and 75 per cent. under 5 years. The apparently high mortality between 25 and 40 is explained by the high morbidity ratio which existed in this series. No death took place between 5 and 25. A man, aged 48, marked "?," with no morbidity against him, was a thin and cadaverous man with whose previous history I was not familiar; also a fatal case, aged 51, was thin and pigeon-chested, but with no actual disease.

GENERAL FEATURES.

Of the lobar cases 5 were apical (4 right side), and of these 4 were associated with severe delirium; 1 was fatal; 5 were "central," all associated with vomiting, and "? gastric" was the diagnosis on the first visit in 4, "? pu., typhoid, or C.S.F." for several days in the other. The signs in this latter were not definite until a day or two before the crisis. I remember well wondering at the time how curious it was that three of these central cases occurred in the same street within three weeks of each other (February, 1918), and were very similar in character. I had no suspicion at the time that they were other than lobar; looking back, however, in the light of the influenza epidemics I feel they were possibly influenzal—the epidemic did not start here until late in June, 1918. I wonder, indeed, if all cases of central (so-called lobar) pneumonia are not influenzal in nature (see later). One of the lobar cases developed pericarditis and arthritis, and one empyema. The latter was the only case in which effusion was marked enough to be recognizable; two of the cases were larval, both lasting three days.

Bronchopneumonias.—One case occurred after swallowing paraffin; two were "anaesthetic"—after herniotomy and appendicectomy respectively; the latter also developed endocarditis, the former was a suspected tuberculous case. Two of the cases (fatal) took place in the influenza seasons, and were possibly influenzal.

Influenzal Pneumonias.—The physical signs varied. I have no doubt that a good many of these cases were diagnosed as bronchopneumonia and lobar pneumonia in former days, at least by the younger generation with no experience of the 1889 pandemic and before the illuminating experience of the recent pandemics. The cases were so few and far between that they escaped recognition. The central type of pneumonia (see above) was common in the recent epidemics, particularly in the epidemic early in 1922. I remember well one of the latter cases in which, on account of the bilious vomiting, dirty brown tongue, low temperature (100°), and absence of chest pain and dyspnoea, I was not certain that I was not dealing with a case of typhoid until the crisis on the seventh day; before this the signs of pneumonia were not definite. These cases would be more difficult to diagnose

in the inter-epidemic periods, when the term "influenza" is not constantly ringing in the ears. Creeping pneumonia was also common. Many of the cases bore a marked clinical resemblance to lobar pneumonia. Of my 72 cases, 4 were secondary to pleurisy (primary involvement of pleura is commoner in influenza than is generally thought), 28 of the cases were unilateral—at least a diligent search found nothing on the other side. The breathing, however, was not the loud, dry breathing of lobar pneumonia, but was more distant and more "crackly." I suspected acute phthisis in not a few of the cases—a suspicion not borne out in a single case so far; a brisk haemoptysis occurred in some of the one-sided cases, and, curiously, in those in whom it occurred the pneumonia was often of short duration. In two cases of this nature the temperature dropped from 103–104° to normal on the third day, and the patients were out walking (without consulting me) on the tenth day. One of the cases developed acute appendicitis, during an attack of influenza; I removed an acutely inflamed appendix and he developed double pneumonia after the operation; it resembled the influenzal cases (much heliotrope cyanosis), so I have not counted it "anaesthetic"; he recovered. One case had intense jaundice—the only one of the 225 in which this was noted. His was a creeping, asthenic pneumonia (temperature 100°) with intense delirium; he threw himself 15 feet out of his bedroom window into the garden below at 1 o'clock on a frosty November morning, his wife and sole nurse—to whom I had given orders that he must not be left a moment—being under the influence of alcohol at the time. He escaped with a few scratches and the crisis occurred two days later. Two of the cases were pregnant—one (third month) carried to term and bore a baby with congenital heart disease (? foetal endocarditis); the mother died three years later. The other (sixth month) aborted a month later and recovered.

These statistics would be incomplete if I did not state that 6 of the patients have died at varying intervals after their attacks; in 4 the pneumonia could be held responsible to some extent for the fatal ending. No. 1 died, aged 26, ten months later of delirium tremens (chronic alcoholic). No. 2 died, aged 3 years, one and a half years after from tuberculous meningitis. Tuberculosis was not suspected until the end. No. 3 died three and a half years after, aged 4½ years, of "chronic interstitial pneumonia"—possibly syphilis of lung, as child was a congenital specific. No. 4 died, aged 47, of "phthisis" three years after influenzal pneumonia when three months pregnant; tuberculosis was not suspected until after pneumonia. No. 5 died, aged 52, of "hysteria gravis" (refused food) three years later; she was examined by six doctors and no signs were found. No. 6 died, aged 10, after an interval of ten months, of "phthisis." A note at time of pneumonia read: "Pn. ? influenzal or tuberculous." Her mother is since dead of phthisis; her father died of pneumonia (suspected of tuberculosis). This case, however, developed severe diphtheria two months before death.

TREATMENT.

I have tried none of the vaunted specifics. The general treatment is as usual—milk, beef tea, albumin water, and plenty of cold water until after the crisis. The most useful drug, in my opinion, is ammonium carbonate—5 grains every four hours for adults and 1 grain for an infant of 1 year, and proportionately according to age. I have often seen a great improvement on the addition of this drug to the medicine, and I now give it in all cases where pneumonia is feared; it seems to act better than the sp. ammon. aromat. Strychnine and digitalis I now never use; the few early cases in which I tried them died; they seem much more useful in the cardiac debility following the crisis—why, I cannot say, unless it be that digitalis raises the blood pressure too much in the acute stage. Morphine I give only to adults, and only in the form of tinct. chlor. et morph. (B.P., 1885), which is soothing without being too depressing to the respiratory centre; 10 minims are given with the carbonate. The hypodermic injection of morphine I think very harmful. I now never give morphine in any form to young children—even the use of tr. camp. co. seems to increase the cyanosis; it must be remembered, however, that the difficulties of controlling the dosage are a factor to be reckoned with in industrial practice. Brandy, I am sure, is of real benefit. I think that the use of the hypodermic syringe—with the apprehension it causes in a good many of the patients—could be done away with without any appreciable increase in the mortality resulting.

TREATMENT OF CHRONIC SYNOVITIS OF
THE KNEE-JOINT.

BY

G. GELSTON ATKINS, M.C., B.A., M.D.,

CAPTAIN R.A.M.C.,

SURGICAL SPECIALIST, 23RD BRITISH STATIONARY HOSPITAL, BAGHDAD.

The question of chronic synovitis of the knee-joint is of supreme importance in the army. Men who suffer from it are not fit for work with a battalion, as they always have an ever-ready excuse for avoiding duty; although in some cases it would be possible for them to continue their work. Every R.A.M.C. officer must be familiar with this type of case, as it is quite common to find in one's surgical wards men who state that, on several occasions, their knee has been "out."

The condition of the affected knee that one commonly finds is as follows: The knee-joint is full of fluid. The vastus internus muscle is invariably wasted, sometimes to a very marked degree. The vastus internus cannot voluntarily be fully contracted; this is best explained by two diagrams representing (1) the contraction of a normal vastus internus, and (2) that associated with a chronic effusion in the knee-joint, as registered by a Mario's tambour.

FIG. 1.

FIG. 2.

FIG. 1.—Normal contraction: A voluntary contraction rises sharply to A, and the top of the contraction curve can be maintained, A—B. Finally the relaxation of the muscle is controlled, B—C.

FIG. 2.—Contraction of vastus internus from a case of chronic effusion in the knee-joint: A voluntary contraction does not rise so sharply as in Fig. 1. There is a sudden drop, A—A1, over which the patient has no control (this can often be detected clinically). The top of the contraction curve cannot be maintained, and the relaxation is not under control.

In old-standing cases some lateral instability of the knee-joint is usually present. Tenderness on pressure may be elicited over various points around the head of the tibia. In most cases it is impossible from the indefinite history to diagnose a torn cartilage, unless the external cartilage is involved, in which case we have the true "clicking knee"—a click being felt every time the knee-joint is voluntarily fully extended—but this is rarely met with owing to the anatomical relationship of this cartilage. It is not attached to the external lateral ligament, whereas the internal cartilage is attached to the internal lateral ligament. In the majority of cases the cartilage is not at fault, and a diagnosis of this condition should not be made unless there is a very definite history of locking of the joint at the time of the original injury. Sudden locking plus sudden "going back" is diagnostic of a torn cartilage; if it diminishes and goes away slowly the trouble is not a cartilage. Again, a definite thickening over the anterior end of the internal cartilage plus pain behind the head of the fibula due to strain on the diametrically opposed portion of the capsule is due to an injured internal cartilage.

A strain of the internal lateral ligament causing an effusion into the joint is a common injury, and very often simulates a torn cartilage. A probable explanation of the clinical signs already mentioned is as follows. The knee receives a strain, an effusion into the joint takes place, and reflexly the vastus internus is thrown out of action; the reason is that the chief nerve of supply to the knee-joint is the nerve to the vastus internus, the nerve passing through that muscle and supplying it before it enters the joint. As a result of this reflex action the vastus internus rapidly wastes and loses tone, and a condition as represented in Fig. 2 is reached. By treatment the effusion is got rid of and the man returns to duty; but owing to the weakened condition of his vastus internus any small twist given to the joint again strains the knee, with the result that more fluid with further weakening of the vastus internus takes place, and so a vicious cycle is established. If, on the other hand, the vastus internus has regained its normal tone, any small twist to which the knee is subjected is at once counteracted by the voluntary bracing up of the vastus internus muscle. In the weakened type of

vastus internus already referred to, this bracing action cannot take place owing to that muscle being reflexly out of action (see Fig. 2, A1).

The treatment is to break this vicious cycle, and the obvious structure to attack is the muscle. If we provide for the injured structures as large a blood supply as is possible, we are using nature's method, and in order to do this it is necessary to use the affected muscles. We have seen, however, that the vastus internus responds only weakly to a voluntary stimulus, and it is therefore necessary first to re-educate this muscle to respond to a voluntary contraction. This is done by causing the patient to keep his leg perfectly straight, in which position he is instructed to practise bracing up the vastus internus; this is done daily. In cases of severe wasting, the use of an artificial stimulus, such as is produced by a Bristow coil, is recommended, until such time as a voluntary stimulus is again exhibited. The muscles of the thigh are massaged and subjected to contrast baths of hot and cold water. This treatment very soon produces a marked increase of tone and of muscular element in the vastus internus. It is possible within a fortnight (if the treatment is conscientiously carried out) to produce an increase in girth of the thigh at this level of from 1 to 1½ inches. No marked improvement will be noticeable unless the effusion in the joint is first got rid of, and this is also done by increasing the blood supply around the joint. The fluid in this chronically inflamed joint is pathological and will be absorbed. The greater the blood supply around the joint the more rapidly will the effusion disappear, and the effusion disappears only at the same rate as the stretched fibrous capsule of the joint retracts. The required toning effect on the capsule is amply provided for by the use of contrast baths, which also favours an increase of blood supply. To increase further the blood supply in the posterior part of the joint the patient is instructed to place the sole of the foot of the same leg as the affected knee on the dorsum of the foot of the sound leg, and by opposing the ankle extensions of the sound leg against the flexions of the bad leg considerable exercise can be given to these muscles, all of which increases the blood supply around the affected joint. The patient is not confined to bed, but he is allowed only light exercise and is instructed that he is not to walk over any uneven ground. Occasionally a tight bandage over wool is applied to the joint at night.

Under this treatment the fluid disappears from the joint, and the vastus internus regains complete tone, which will prevent a further recurrence of effusion into the joint. There is one type of knee-joint occasionally met with in which all methods fail to get rid of the fluid, except aspiration. As soon as it is decided that one is dealing with a case of this kind, aspirate at once, as it is all-important to get rid of the effusion. If the fluid is due to any intra-articular condition, the effusion will recur, and this fact helps in the diagnosis of an otherwise difficult case. If an operation is to be done, the tissues to be operated on and the knee-joint have been brought to a very healthy condition by the treatment outlined. Tender spots found at the insertion of tendons about the knee-joint are due to a local effusion of the fibres at their insertion. The above treatment, by contrast baths and massage, will cause these local patches of effusion to disappear. In a series of 300 cases treated by the above method it was found that in 75 per cent. of the cases no recurrence of the effusion into the joint occurred for some time afterwards, after continued football, etc. In these cases, the original symptomatic diagnosis was altered to "strain of knee-joint." If a further effusion occurred, some intra-articular lesion was diagnosed. Care must be taken to eliminate tuberculous knee-joint, and also an effusion of the joint due to a hypertrophic infrapatellar pad of fat, in which case suitable limitation of complete extension must be provided for.

In conclusion, chronic effusion of the knee-joint is, in 75 per cent. of cases, not due to an injured cartilage, but to a strain of some structure around the joint. This can be effectively dealt with by re-education of the vastus internus, plus the production of as large an increase as is possible in the blood supply around the joint. This latter is obtained by (1) contrast baths; (2) limited active exercise of all muscles around the joint; and (3) massage. If this treatment is instituted in every case of chronic effusion of the knee-joint the number of operations for a so-called injured cartilage will diminish, and many men will be able to enjoy various forms of sport which they otherwise would not be able to take part in for fear of "putting out" a knee again.

NEURO-SYPHILIS WITH SEVERE LARYNGEAL CRISIS: TRACHEOTOMY.

BY

JOHN W. LEITCH, M.A., M.B., F.R.F.P.S.GLAS.,

VISITING E.A.R. NOSE AND THROAT SURGEON, BELLARHOUSTON HOSPITAL;
DISPENSARY SURGEON FOR DISEASES OF THE EAR, NOSE AND THROAT, GLASGOW ROYAL INFIRMARY.

CONSIDERATION of the symptoms presented in the case here reported points to an irritative cortical lesion as the most likely cause of the severe laryngeal crisis. The experiments of Krause, Semon, and Horsley have shown that there is a centro for adduction of the vocal cords in each cerebral hemisphere at the anterior part of the lower end of the ascending frontal convolution. Irritation of either centre results in adduction of both cords, while abduction though represented is more difficult to produce, and is rather governed from the lower centres in the floor of the fourth ventricle.

A pensioner, aged 35, was admitted about 3 a.m. on January 15th, 1922, as an urgent case suffering from respiratory embarrassment and cyanosis, having been found in this condition by the police. I saw him first about 8.15 a.m., in response to an urgent call, as his symptoms were becoming worse. He was then propped with pillows in bed in a semi-recumbent position, had a haggard and anxious expression, and looked seriously ill. The pulse was regular, 72 a minute, and of good quality and tension. Respiration seemed shallow and difficult, but there was no stridor. He was apathetic and apparently unable to raise his voice above a whisper. In a few minutes respiration ceased altogether, and his pulse then became weaker and ceased to be palpable. Tracheotomy instruments had meantime been got ready, and a low tracheotomy was then performed by a single incision of the scalpel. The tracheotomy tube was inserted without delay, but respiration did not begin, and it was noticed that there was no bleeding from the tracheotomy wound. Artificial respiration by compression of the lower ribs (Howard's method) was resorted to, and in a short time spontaneous breathing returned. A few seconds later, and before consciousness returned, there were convulsive movements of the arms and legs sufficiently violent to throw the tray with the instruments off the bed and to give some trouble to keep the patient from being jerked out of bed. He then appeared to waken up, lay down quietly, and was able to phona quite well when the finger was placed over the tracheotomy tube. Three hours later, when I saw him again, he had lost his anxious look and expressed himself as feeling well. The tube, which had slipped out of the trachea, was replaced in position.

Examination of the larynx showed that the epiglottis was infantile in type and hid the greater part of the vocal cords. The arytenoids moved normally, and there was no oedema or other sign of abnormality. There was a superficial ulcer round the fraenum of the tongue. Knee-jerks were exaggerated, especially on the left side, and there was slight clonus of the left ankle. There was no noticeable "scanning" speech. The pupils were equal, moderately dilated, and reacted well to light. The urine contained some albumin and a trace of blood. On January 15th direct laryngoscopy with cocaine anaesthesia showed the movements of the anterior parts of the vocal cords as far as the vocal processes to be normal, but the posterior one-third moved sluggishly and did not approximate fully. There was some redness and oedema of the mucous membrane of the arytenoids and false cords, but this was considered to be due to passive congestion, and not inflammatory. There were no further laryngeal symptoms, and in ten days the tube was removed and the wound healed up. On January 30th examination revealed a painless swelling the size of a hazel nut in the left anterior pillar of the fauces. A week later this gumma had completely gone, and another had appeared at the anterior border of the

larynx. This also subsided within a week, leaving no scars, under whose care the patient was, has kindly supplied the following further details. He had frequent diplopia, lightning pains in legs, girdle sensation, frequency and preipitancy of micturition, difficulty in walking in the dark. The knee-jerks became slightly sluggish, but were never absent, and there was impairment of tactile sensation in the legs. The pupils continued to react actively to light. The Wassermann reaction for blood and cerebro-spinal fluid was positive. The cerebro-spinal fluid gave a normal cell count and protein content. The colloidal gold reactions showed a strong metachromatic curve—namely, 53221100000.

The patient was discharged from hospital on March 3rd, 1922, to continue antisyphilitic treatment, which had been confined to mercury and iodide on account of the albuminuria.

The occurrence of general convulsions during recovery in this case would be explained by extension of the irritation to neighbouring centres, as frequently occurs in laryngismus stridulus. The appearance and rapid subsidence of gummata elsewhere supports the view of a cortical lesion, while the pang of localizing symptoms points to a gummatous formation in the membranes covering the cortical centre rather than in the brain substance. Had there been a lesion in the neighbourhood of the pons or fourth ventricle other cranial nerves could scarcely have escaped being involved.

At the same time the possibility of early tabes has strong claims. It is known that such crises are an early—and sometimes the earliest—symptom of this disease, and that the spasmodic attacks vary greatly in frequency, occurring sometimes only two or three times in the course of years, and sometimes daily or oftener.¹ Yet a diagnosis of early tabes does not negative the probability of the laryngeal crisis in the present instance being due to an irritative cortical lesion caused by a gumma.

Another point worthy of note is the quick recovery, even after the cessation of both circulation and respiration. The question at once arises as to how soon after apparent death measures for resuscitation must be regarded as of no avail. A recent paper in the *BRITISH MEDICAL JOURNAL*,² in which among other cases one of resuscitation two hours after apparent death is recorded, is of interest in this connexion. It seems reasonable to conclude that, at least in cases where there is not an obvious cause of death, measures for resuscitation should not be lightly abandoned. Particularly does this apply in cases of sudden death under chloroform or other general anaesthetic, in which the patient is usually comparatively vigorous, and in which perhaps a rapidly performed tracheotomy followed by Howard's method of artificial respiration might be tried more often with success. Free entrance of air into the lungs is assured, there is less disturbance of the patient than with Sylvester's method of artificial respiration, while external massage of the heart is at least as efficient; and finally, it is much less drastic than direct massage of the heart through an incision into the pericardium.

I am indebted to the Minister of Pensions for permission to publish the above.

THE TREATMENT OF ASYLUM DYSENTERY BY MEANS OF ANTIDYSENTERY SERUM.

BY

P. LORNIE, O.B.E., M.D.,

SENIOR ASSISTANT MEDICAL OFFICER, NONMOUTHSHIRE ASYLUM;

AND

D. ELLIS JONES, M.R.C.S.,

JUNIOR ASSISTANT MEDICAL OFFICER, NONMOUTHSHIRE ASYLUM.

The results in the following cases of asylum dysentery, treated at this institution during the past two years, indicate the value of antidyenteric serum. The matter is of importance, since during the second half of 1921 the number of persons in mental hospitals who were attacked by the disease was 728, and of these 126 died.

The serum mainly used was supplied by Messrs. Barroughs, Wellcome, and Co., and was prepared by injecting horses with cultures of Shiga's, Flexner's, and Kruse's bacilli. In Cases 5 and 6 a serum of a similar nature prepared by Messrs. Evans, Lescher, and Webb was administered.

Case 1.—Female, aged 45. The patient, who was in an extremely debilitated state, developed diarrhoea. On the fifth day of the attack the dejecta contained blood and mucus. No previous attack of dysentery had been recorded. The milk diet was stopped and a diet of albumen water, Benger's food, and Valentine's meat juice substituted. At the same time the patient was put on a bismuth mixture and iodoform enemas. This treatment was continued for six days without improvement; 40 c.cm. of the serum were then injected into the peritoneal regions. In three days' time the blood and mucus had disappeared, and the patient showed a marked physical improvement. Convalescence was somewhat gradual, but no further traces of blood or mucus were detected, although diarrhoea continued in a mild form for two weeks after the injection. There was no pyrexia during the illness. Nine months afterwards the patient developed slight diarrhoea, cardiac weakness, and pulmonary congestion, and died. At the necropsy the mucous membrane of the large intestine was much injected, but there was no ulceration.

Case 2.—Female, aged 41. For three months this patient had suffered from intermittent diarrhoea, which had been treated with salines and bismuth. Blood and mucus then appeared in the dejecta. Antidyenteric serum, 45 c.cm., was administered. The dysenteric symptoms disappeared in three days' time. A week after the injection the bowels had not opened for twenty-four hours; twelve days after injection the stools were normal. No pyrexia was recorded during the course of the disease. The patient one year after treatment has had no recurrence.

Case 3.—Female, aged 21. This patient had suffered from diarrhoea for three days when blood and mucus were observed. There was slight pyrexia, ranging round 100°. Antidyenteric

serum, 25 c.cm., was given hypodermically. In five days the temperature had fallen to normal and the evidences of colitis had disappeared.

Case 4.—Female, aged 46. This patient developed a severe dysenteric attack, with blood and mucus, much abdominal pain, and pyrexia up to 103°. She was given 25 c.cm. of the serum, and after five days no further looseness of the bowels was recorded.

Case 5.—Male, aged 74. This man suffered from a severe attack of dysentery with slight pyrexia. Small doses of salines were given at frequent intervals. After two days of the saline treatment no blood or mucus was observed in the dejecta, and the temperature was found to be subnormal. The diarrhoea, however, continued, and two days afterwards there was a recurrence of the pyrexia and traces of blood and mucus were again detected in the motions. The patient was then given an injection of 25 c.cm. of serum, and after an interval of two days only two evacuations were recorded in the twenty-four hours, one of which was formed. There was a marked physical improvement twenty-four hours after the administration of the serum.

Case 6.—Male, aged 72. This patient, who had two years previously suffered from dysentery, again suffered from an attack of the disease. He was at the same time suffering from pernicious anaemia in a state of remission. For the first two days there were frequent evacuations containing blood and mucus, and associated with hyperpyrexia ranging up to 103.4°. On the third day the temperature was found to be subnormal, but the colitis continued unabated. On the fourth day the temperature rose to 100° and 40 c.cm. of antidysentery serum were injected. On the following day the temperature was normal and the evacuations had decreased in number, but the blood and mucus were still present. Next day the number of motions was not diminished but blood and mucus had disappeared. In a further three days' time he had only one formed action, and shortly afterwards he was complaining bitterly of constipation.

Case 7.—Male, aged 53. This patient developed an acute dysenteric attack with a temperature ranging up to 104°. Twelve hours after the commencement of the attack 40 c.cm. of the serum were given. The temperature fell to normal within twelve hours after the injection, and during the day only three dysenteric motions were passed, although eight had been passed on the previous day. Two days afterwards he had only one formed motion.

Case 8.—Male, aged 67. This inmate suffered from a moderately severe dysentery with an even temperature of 101°. Only 25 c.cm. were used. The condition at once cleared up and at the end of a week he was again in his usual state of health.

Case 9.—Male, aged 82. This man developed dysentery at the same time as the previous case. The same treatment was used, and the course of the disease was exactly similar to that recorded under Case 8.

Case 10.—Female, aged 44. This patient was found to be suffering from a severe attack of dysentery, associated with blood and mucus, tenesmus, much abdominal pain, very frequent motions, and high pyrexia. She was given 20 c.cm. of serum daily for four successive days. The temperature had fallen to normal by the fourth day, and the tenesmus and pain had disappeared, while the number of motions had greatly decreased. By the fifth day mucus and blood had disappeared. The patient rapidly recovered, although a slight diarrhoea lasted for a week afterwards. This patient two years previously had had an attack of equal severity, which took a month to clear up under salines.

It is somewhat difficult to dogmatize on such a small number of cases, but owing to the comparative freedom of this institution from dysentery it has taken over two years to collect these records. The results are certainly of a more satisfactory nature than any obtained in this institution before the introduction of serum treatment. Apart from the rapid clearing up of the blood and mucus and the cessation of the diarrhoea, the rapid fall in the temperature and the immediate and marked physical improvement have been outstanding features.

FURTHER OBSERVATIONS UPON EXTERNAL HYDROCEPHALUS.

BY

CECIL E. REYNOLDS, M.D.CAL., M.R.C.S.,

LOS ANGELES.

IN THE BRITISH MEDICAL JOURNAL of July 16th, 1921 (p. 66), and elsewhere, I have described typical cases of acquired external (occult) hydrocephalus and the treatment adopted. These clinical pictures have been found with great constancy in numerous subsequent cases. The treatment, however, has been simplified in many cases. A striking fact has presented itself, in that congenital external hydrocephalus exhibits certain differences of character from the acquired form, and, since the operative outlook is much worse in the congenital cases, it is important to be acquainted with diagnostic methods other than the history as given by the parents.

A congenital external hydrocephalus is frequently associated with microcephaly. The reason for this is that the

brain pulsation is a great factor in the normal development of cranial capacity. When there is a layer of fluid external to the brain this expansile pulsation is diminished. Curiously, the ventricles do not enlarge as a rule in external hydrocephalus, at least not to any extent. The brain instead shrinks, the skull is often arrested in development, and the subarachnoid and subdural fluid stays abundant because the foramina of Magendie, Key, and Retzius are patent, and often there is no tela choroidea or arachnoid covering the fourth ventricle at all.

Many patients have normal-sized heads, but appear mentally defective with some bulbar paresis, and varying degrees of spastic or flaccid diplegia or paraplegia. Invariably the legs are more affected than the arms, since, next to the cerebellum, the region of greatest pressure seems to be the leg centres at the vertex where a puddle collects around the arachnoid villi, in the same way as rain collects and eddies at the mouth of a partially blocked drain. An opening in the dura in this region unless promptly closed is almost inevitably fatal in these cases, for cerebro-spinal fluid escapes in a jet and continues in spite of a vertical posture of the head and with ever-increasing frequency of respiration until the respiratory centre fails or multiple capillary cortical haemorrhages occur. The safest approach is a graduated suboccipital deduralization in chronic cases, which is also the more logical. Supratentorial measures are subsequently required in a certain proportion of cases. Many cases of so-called Little's disease are therefore not due to haemorrhage nor to trauma at the vertex, the vertical symptoms being secondary to defect in function of the basal membranes.

I operated upon a four-days-old infant suffering from continuous right-sided Jacksonian fits following a prolonged forceps labour, and found excessive clear fluid at the vertex, but no haemorrhage, as was expected. The dura was left open over the Rolandic area in this case, and the child made a perfect recovery and is now normal. Such a procedure would have been followed by a very severe reaction in a chronic case.

It is not easy to say why a uniform increase of external fluid produces a flaccid and sometimes a spastic diplegia, but, contrary to expectation, the flaccid type of this disease has often a better prognosis than the spastic. This latter fact possibly indicates that the cerebellum has been more compressed than the cerebrum in the well-nourished flaccid cases. Another point is that the congenital cases do not have fits, as far as my observation goes, whereas the acquired cases of external occult hydrocephalus always do, even when the disease has been acquired within the first few days of extra-uterine life. I believe that the congenital cases have had their fits *in utero*, or the cerebral devitalization has progressed beyond the convulsive stage before birth.

In a series of 29 cases of external hydrocephalus operated upon there has not been one with either clinical or serological signs of syphilis, nor with appreciable enlargement of the head. On the other hand, cases of internal hydrocephalus due to cerebello-medullary adhesions show a high percentage of positive Wassermann reactions, and, of course, great cranial enlargement. Such cases are scarcely worth surgical consideration.

The acute specific diseases, especially tonsillar infections, as well as birth trauma, appear to be the usual causes of primary external hydrocephalus. Without doubt, the frequent textbook statements regarding "ex vacuo" accumulations of fluid are true of local collections in certain instances, but I believe that when extracerebral fluid is general, the brain has shrunk because the fluid accumulated owing to defective powers of absorption of the basal arachnoid, and that the fluid did not accumulate to fill the vacuum left by an otherwise unaccountable atrophy of the cortex. In other words, there seems to have been a tendency in the literature to put the cart before the horse in this matter. Why the brain shrinks and the ventricles do not dilate in external hydrocephalus is purely a question of physics.

THE third conference of the International Union against Tuberculosis will be held in Brussels from July 11th to 13th. The subjects for discussion include: (1) Tuberculosis in the child, (a) before school age, and (b) during school life; (2) antituberculosis prophylaxis in the home by the visiting nurse; and (3) the work of the tuberculous during and after cure. Visits will be organized to the different antituberculosis establishments in Belgium. Those who wish to become members are requested to send their names and addresses with subscription (£1) before June 26th to the secretary, International Association for the Prevention of Tuberculosis, 20, Hanover Square, W.1.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ADDISON'S DISEASE, RAPIDLY FATAL.

The following case is of interest on account of the well-marked signs and symptoms, and in the light of the *post-mortem* findings.

The patient, a boy aged 17, was admitted to hospital in a very exhausted condition. The skin was so dark in colour that he was thought to be a mulatto. It was stated that weakness and discoloration of the skin had begun three years before, and seemed to date from a severe attack of sickness. Both the weakness and discoloration had persisted, but had varied considerably in degree from time to time. The bronzing of the skin was noticed to be most marked always when the patient was very exhausted. He had worked only intermittently since the onset of the symptoms, but had never been confined to bed until a week before admission, when he became extremely exhausted, and complained of pains over all his body. The boy had been much troubled with headaches, but had had no sickness after the first attack three years before, and the appetite and digestion had been good; indeed the appetite had been voracious. He had complained from time to time of pain in the lower part of the abdomen on the right side. During infancy the left knee had swelled and required incision, and had not healed finally till two years later. Apart from this the child had seemed healthy. The family history was negative, except that the father suffered from bronchitis.

On admission the patient was wasted and extremely weak, but was moderately well developed. He was so light that a nurse was able to carry him down the ward in her arms. He was apathetic and dazed, and did not speak unless roused. The skin was cool, dry, and deeply bronzed. The conjunctivae were very slightly tinted. There were no enlarged glands to be felt. Round the left knee there was extensive scarring with considerable limitation of movement. The temperature was 98.2°, the pulse rate 104 a minute, and the pulse was running and of very poor quality. The blood pressure measured 64 mm. of mercury. The heart was not enlarged, and the sounds were weak but pure. A blood count showed that the red blood cells numbered 5,200,000, the haemoglobin was 55 per cent., and the white blood cells numbered 15,000. Except for flattening of the percussion note at the right apex the respiratory system appeared normal. The respirations numbered 23 a minute. The tongue was dry and furred, and the lips and teeth covered with sordes. The pharynx were slight tenderness and resistance fossa. The liver and spleen were constituents were found in the urine.

A few hours after admission the patient became very restless; the following morning he had a convulsive seizure and became as marked especially by rigidity flexed at the elbows, the arms, retracted, but there was no cervical resent. There were no knee-jerks, indefinite. There was no cyanosis.

From this but they slowly, unconsciousness.

On *post-mortem* examination the heart appeared healthy except for an almost complete absence of epicardial fat. Both lungs were extensively adherent to the chest wall, and showed limited chronic tuberculous lesions at their apices. The liver, spleen, and kidneys showed marked *post-mortem* change, but otherwise appeared normal. Neither suprarenal gland could be identified, so the whole mass of tissue above the kidney was dissected out on each side for microscopic examination. There was a caseous and calcareous gland mass lying close to the coeliac axis extending towards the left semilunar ganglion. The thymus was persistent but not prominent. The thyroid gland showed marked congestion. There was oedema of the brain.

Microscopically the thymus showed a nearly normal structure with some congestion. The thyroid showed generalized interstitial inflammatory change; the stroma showed marked cellular proliferation, while in places the colloid was eroded and vacuolated, and in other parts had disappeared; the gland had the appearance of great functional activity. The pituitary showed intense congestion but otherwise nothing of note. The tissue from the right suprarenal area was divided into several blocks, and sections examined. In none of the sections could suprarenal tissues be found. The left semilunar ganglion was embedded in fibrous tissue. The left suprarenal gland was embedded in fibrous tissue, but the nerve elements showed only slight tuberculous change. The tissue from the left suprarenal area was similarly treated, and two of the blocks showed isolated islands of suprarenal tissue surrounded by dense fibrous tissue and caseous material. The cells were of the cortical type, and many showed extensive vacuolization with loss of nuclear staining. No medullary suprarenal tissue was recognized.

The most interesting features of the case were: (1) The practically complete absence of suprarenal tissue and the length of time during which this condition must have existed before death occurred. (2) The marked activity of the thyroid gland, probably compensatory in nature, affording evidence of the correlation of function of the two glands. (3) The persistence of the thymus gland, in view of Wiesel's suggestion that adrenal insufficiency hinders its involution.

I wish to thank Professor W. K. Hunter for permission to report the case, and Dr. J. A. G. Burton for the histological details.

CHRISTIAN M. FLEMING, M.B., Ch.B.,
Late House-Physician, Royal Infirmary, Glasgow.

COBRA BITE.

Cases of recovery from cobra bites, after manifesting all the symptoms of the effect of the venom in the central nervous system, are so rare that the following account should be placed on record:

A young Anglo-Indian employee of the Bengal-Nagpur Railway had recently captured a female cobra (*Naja tripudians*) 4 ft. 6 in. long, and on May 24th, 1921, was exhibiting it to some friends of his, when it suddenly bit him twice on the dorsal surface of his right wrist, at about 8.45 a.m. A string and handkerchief were tied tightly above the bite, and he was brought to hospital, where he was seen about 9 a.m. A rubber tourniquet was applied tightly round the forearm, and gold chloride was injected subcutaneously around the bites after they had been incised. The patient was placed in bed in hospital and two injections of antivenene, 20 c.cm. each, were administered under the skin of the abdominal wall. He was suffering agony from the constriction of the ligature and tourniquet, and the arm was getting considerably swollen. The ligatures were removed about 10 a.m., much to his relief, and I warned the nurse on duty to let me know as soon as he presented any untoward symptom. At 10.55 a.m. it was reported that he was restless and said he could not see. On examination I found that he had complete ptosis of both eyelids, he was bringing up a considerable amount of sticky saliva and mucus from his mouth, and his speech was immediately is was done mptoms of mucus in-creased greatly, and he vomited up bile and mucus twice; he then lost all power of speech and of swallowing, and had severe spasms. He was quite conscious all the time, and was very distressed by the constant flow of sticky mucus, which had to be swabbed out of the back of the pharynx very frequently. He lost control of his sphincter ani, and had three copious watery evacuations within an interval of ten minutes. I ordered continuous oxygen inhalation at 11.30 a.m. as the respirations had become very shallow and sighing, interrupted every few minutes by a severe spasm, during which the back became arched, after one of which respiration stopped altogether. The patient was lifted to the floor, and I had to do artificial respiration for about a quarter of an hour before the respiratory movements recommenced and became in any way regular. Once this was re-established he seemed to turn the corner. From this time (12.45 p.m.) onwards the symptom that troubled the patient most was the flow of sticky mucus; he had no more spasms. I saw him again about 2 p.m., when the respirations were still regular, but the pulse, which had been 80 to the minute, had gone up to 120, and later rose to 132. He complained by signs of great thirst, so I gave him ice to suck, which relieved him a little, but he still could not swallow water. I ordered atropine sulphate gr. 1/100 at 4.15 p.m. with the hope that it would not only stimulate the respiratory centre but also come up to my expectations; the and the respiratory movements started to talk again, although the speech was very slurred, and I began to hope that he would pull through. At 8 p.m. the pulse became slower, although his temperature had gone up to 102° F. At 10 p.m. he was still restless, and I ordered that another atropine injection should be given if he had any respiratory trouble. At 10.30 p.m. he complained of a severe pain over his heart and breast, and was again injected. This had a sleep for forty minutes, and from He slept off and on during the night, and by 7 a.m. on May 25th the only paralytic symptom noticeable was ptosis, which finally disappeared by 10 a.m. His only complaint now was the arm, which was very inflamed and swollen, and was sloughing where the gold chloride was injected. The sloughs subsequently came away, and afterwards a skin graft was applied; the patient was discharged from the hospital without any contraction.

In this case the cobra, which was in captivity, undoubtedly injected a lethal dose of venom into the patient, as evidenced by his symptoms, and the success attending the treatment was due to the injection of massive doses of Calmette's antivenene direct into the circulation. A contributory cause to the recovery was, I am convinced, the injection of atropine, which, so far as I know, has not previously been given in such cases. The venom of the cobra kills by paralysis of the respiratory centre, while atropine in medicinal doses stimulates the respiratory centre. All secretions from the mucous membrane and lungs are also diminished, which contributes to an appreciable extent in stimulating respiration. In this case the action of the atropine was most marked in diminishing the secretion of the saliva and the mucus of the buccal mucous membrane, and also in stimulating the respirations. I would strongly recommend its trial in addition to other remedial agents in every case of cobra bite.

V. S. JOHN CHOLLY, L.R.C.P. and S. Edin.,
Medical Officer, Barrackpore, Bengal-Nagpur Railway.

Reports of Societies.

DIATHERMY IN SURGICAL PRACTICE.

At the meeting of the Section of Surgery of the Royal Society of Medicine on June 7th, with the President, Mr. RAYMOND JOHNSON, in the chair, a discussion took place on "Diathermy in surgical practice."

Mr. CLAYTON GREEN, in opening, said that diathermy was a method of treatment on the principle of the cautery, but with the difference that whereas with the cautery destruction was limited to the area practically in contact with the cautery point, in diathermy, as used for surgical purposes, the area of destruction was enormously increased. The chief advantage in applying this method as opposed to the cautery was the great ease with which it could be directed to growths in relatively inaccessible positions. It was his dissatisfaction with ordinary operative procedures in cancer of the tongue and floor of the mouth which led him to adopt diathermy as an alternative. In the more advanced cases it had the advantage that it did away with any question of cancer infection of the wound, it allowed destruction of a much wider area of tissue than could be obtained with the knife, and it was applicable to cases otherwise inoperable or in which an operative procedure of such magnitude would be necessary as to be extremely hazardous. It had certain disadvantages, however; in the first place, it was advisable to ligate any of the main vessels across the route traversed by the cautery. In all cases where it was necessary to remove a portion or the whole of the tongue or the floor of the mouth he invariably tied the vessels. Another disadvantage was that the wound was of the nature of a foul slough produced in a foul cavity. Although, in cases submitted to operation in the ordinary way, a certain amount of sepsis was more or less inevitable in the mouth, he admitted that the amount of sloughing appeared at first sight to be a detrimental factor in the application of this method. In the result, however, only one of his cases treated by diathermy showed any ill effects arising from this extensive sloughing. Yet another disadvantage was that the bone touched by the point of the cautery was necrosed, and the amount of time necessary for the separation of such necrosed bone was several weeks, during which time the patient had to be scrupulously careful to keep his mouth from anything which could give rise to sepsis. Again, in operating with diathermy a considerable amount of care had to be taken both by the operator and the manipulator of the machine, otherwise the patient or the operator or both might be burnt. On one occasion he burned himself considerably, and the burn took a long time to heal. He had submitted 31 cases of carcinoma of the floor of the mouth, tongue, or tonsil to operation by this method, and there were no complications, and only one death (from bronchopneumonia). He attributed the immunity from pulmonary trouble to the fact that no blood whatever trickled down the trachea into the lung. Of the 31 cases there were 6 in which there had been no recurrence, either locally or in the glands. In a certain number a local cure was effected so far as the primary focus was concerned. With few exceptions there had been alleviation. He had also applied the method to bladder trouble, though in comparatively few cases. So far as his experience went, small localized growths were efficiently treated and well controlled by intravesicular cystoscopic methods, but when the growth was larger the choice would lie between resection of the bladder wall and the destruction of the papillomata by the suprapubic opening. The latter was the method he had practised in 6 cases. The scarring of the bladder did not appear to interfere with the functioning of the ureters. He would not urge that diathermy should be adopted in preference to any other method, but he thought that it had a good deal to recommend it. In the large group of inoperable cases where the surgeon had to turn away, reluctantly admitting his inability, this method supplied a want in a most admirable manner, and gave relief where no other means of relief could be found.

Mr. DOUGLAS HARMER spoke of the treatment by diathermy of malignant growths, particularly of the upper air-passages. Ordinary excisions with the knife gave very unsatisfactory results, and with the exception possibly of cancer of the vocal cords and of the lip one could hardly be certain of curing more than one-third of the malignant cases by simple

excision. With diathermy the recurrence of a growth could sometimes be prevented quite successfully even if it had failed to respond to ordinary cutting methods. Diathermy had completely altered his own opinion and that of his colleagues with regard to the treatment of carcinomas of the floor of the mouth. If these cases could be obtained before there were any palpable glands in the neck they did well; and it was surprising what good results might be obtained in cases of carcinoma of the tongue, even when very extensive. Carcinoma of the tonsil was one of the worst forms of carcinoma to be met with, but here again there was no question that with diathermy good results could be obtained, without recurrence for three or more years. In some very extensive carcinomas diathermy gave great relief of pain. Without hesitation he would declare that, for this particular type of growth in the floor of the mouth diathermy was the treatment of choice. With many growths it was advisable to excise first and then treat the cavity with the button or flat plate so as to heat it up thoroughly and sterilize it completely. In cases of carcinoma of the jaw he exposed the growth freely; if there was a great mass of it he cut it away or removed with the spoon, and treated the remainder of the cavity unmercifully with the cautery. In view of the subsequent application of diathermy it did not matter that some part of the growth remained after excision, because the thorough sterilization by the cautery did away with any risk of infecting the wound. In applications to the face there was a danger that in attempting to get rid of a carcinoma inside the cheek the skin outside the cheek should be destroyed; therefore his applications were made very gently and tentatively in this region. He thought he could say that with diathermy there were no bad results. At St. Bartholomew's Hospital well over 100 cases had been treated, and the mortality was limited to two patients who had died of secondary haemorrhage; but secondary haemorrhage was no more common with this method than with ordinary cutting operations. There was certainly extensive sloughing, and the wound presented a very untidy and unpleasant appearance, but there was practically no toxæmia. The electric current also did away with the pain in a way that cutting operations failed to do. It was remarkable how it "knocked the sensory nerve sideways." Therefore it was of value in inoperable cases, if only on account of the relief of pain. The scar which was formed over the diathermic wound was invariably smooth and pliable. In certain cases of lupus where it was advisable to get a rapid recovery he had found diathermy superior to any other method of treatment; in naevi which were vascular and unsightly it was possible to bring about rapid coagulation, and so get rid of the swelling; and in certain innocent tumours such as warts, which were liable to recur if cut out with the knife, better results could be obtained with diathermy than with ordinary surgery.

Dr. E. P. CUMBERBATCH exhibited some cases to the Section, and said that he had treated by diathermy certain rodent ulcers which had resisted other forms of treatment, including ionization, x rays, and radium. One case of rodent ulcer occurred in an old woman who had been treated previously for the same condition by zinc ionization; the ionization had caused the disappearance of the ulcer, but it had recurred, and ionization then had no effect upon it whatever. Diathermy was applied, and there were no signs of recurrence now after three or four years. A case of naevi which was treated by diathermy in 1910, on the first introduction of the method to British electrotherapeutists by Nagelschmidt, was seen by him seven years later, when it had recurred, and he brought about its disappearance again by the same method.

Mr. CECIL ROWNTREE said that for some years he and his colleagues at the Cancer Hospital had been using diathermy in advanced cases of cancer. At the outset there were some technical difficulties arising from the use of an entirely new method. One question was whether the use of one or of two poles was the more satisfactory. One of his colleagues used both poles on the tumour, and, he thought, got more extensive destruction in less time, and with better ultimate results, than others who employed the unipolar method, which, however, was the more generally used. Another difficulty in treating mouth cases was the formation of vapour in the mouth, which obscured the view; and then, again, there were difficulties arising from the use of the anaesthetic and from the various gags and specula. He had met with secondary haemorrhage with no greater frequency than after ordinary operations with the knife, but there seemed always to be a fear that secondary haemorrhage might arise. He was convinced that diathermy did sometimes produce a very

intense and rapid enlargement of the glands of the neck. On two occasions when this occurred he, perhaps foolishly, tried to remove the glands, and found them converted into a pus-containing cancerous sac. There was no possible doubt as to the value of diathermy treatment in advanced cases. It relieved pain, lengthened the patient's life, and encouraged hope. In a certain number of the earlier growths it was also most valuable. He felt strongly inclined, where possible, to excise the glands and then to do the diathermy.

Mr. W. G. SPENCER said that he had had no opportunity of actually employing diathermy save in one or two exceptional cases. He could only congratulate the previous speakers upon their results, and if he deprecated what he thought were extreme views as to the value of the method it was not because he wished to minimize at all its great importance when applied in certain cases. He thought that one of the cases shown by Dr. Camberbatch as an instance of the good results of diathermy—an epithelioma of the scalp—might have been excised with a plastic operation, which would have been a fairly simple matter. The patient now appeared to be developing an epithelioma following the diathermic scar. That was very likely to follow as a result of burning. He could not agree with the proposal to treat either by diathermy or by x rays or radium simple cases of rodent ulcer on the face or elsewhere. They could be excised, especially if one went deep enough, and with the plastic operation they were healed up within a week, and nothing more was to be seen of them unless the patient developed rodent ulcer elsewhere. He congratulated Mr. Harmer upon the way in which he had treated endotheliomas of the roots of the tongue and the fances, but in the case of ulcers of the floor of the mouth he could not help wondering how they were diagnosed. Was it proposed to apply a form of canterly to an ulcer upon which a definite diagnosis had not been made? The late Sir Henry Butlin had made great efforts to protect people from cancer of the tongue by getting general practitioners to persuade their patients to have these patches cut out and submitted to microscopic examination. He deprecated the application of the cautery to these patches in the absence of such an examination. He could not agree with the application of the cautery after excision; in the case of the tongue, for example, after getting the mouth clean, it was easy to sew up the surface of the tongue, getting the healthy portion of the tongue to cover in the raw surface, and so obtain healing by first intention in the mouth, and afterwards to get a mobile tongue. He believed that diathermy was of use within certain well-defined limits: Mr. Clayton Green's application of diathermy to bladder conditions was a most important advance in surgery, but he protested against the extension of diathermy to all sorts and kinds of conditions indiscriminately.

Mr. PHILIP TREXER said that in some cases of rodent ulcer which he had treated by diathermy he had been struck by the suppleness of the scar which resulted; he had expected to find the scar so firm and hard that the patient would not be able to open his mouth. There was no doubt that for advanced cases of rodent ulcer diathermy offered the greatest promise. Many cases of early rodent ulcer would also be treated satisfactorily by this method, but in a great many of them, when the ulcers were small, excision was the simpler and quicker procedure. As for the use of diathermy in malignant disease, epithelioma of the tongue might be destroyed by a combination of surgical measures and diathermy in which any part that could not be removed by the knife should be destroyed by the cautery; but in the cases of which he had had experience there was frequent recurrence in the neck after operations in the region of the floor of the mouth. In the treatment of malignant disease the best method was early and complete removal, and this depended upon early diagnosis; but in addition to the surgical methods there were certain auxiliaries, of which diathermy was one of the most useful, and he would rank it before x rays or radium. With regard to accidents following diathermy, he had had one case of secondary hæmorrhage and one case in which a patient had a very bad burn. He quite agreed as to the remarkable disappearance of pain after diathermic applications.

The PRESIDENT said that it had been a very enlightening discussion, though he confessed himself still in doubt whether in carcinoma of the mouth diathermy should be reserved for the cases which were to be regarded as otherwise inoperable or only amenable to very extensive operation, or should be regarded as the treatment of preference in all cases.

GENETIC ORIGIN OF DEMENTIA PRÆCOX.

At a meeting of the Medico-Psychological Association of Great Britain and Ireland, held in the rooms of the Medical Society of London, on May 25th, the President, Dr. C. HUBERT BOND, made sympathetic reference to the loss by death of Dr. Blakistoun, Dr. Abbott, and Dr. James Middlemass. Of the latter he spoke in terms of high eulogy for his work on the Council of the Association, and in the compilation of the Association's *Handbook*. A resolution of sympathy was carried by members rising in their places.

Sir FREDERICK MOTT, K.B.E., F.R.S., read a paper on the genetic origin of dementia præcox, which was illustrated by micro-photographs and drawings. He began by mentioning previous publications he had made concerning the changes he had found in the cells of the central nervous system, especially the cortex, which would account for suspension or suppression of function, and consequently disintegration of the psychic unity. He assumed that the less severe changes denoting hypofunction would account for cases in which recovery or partial recovery occurred. He drew attention to the fact that he had investigated cases which began with what was diagnosed as confusional insanity and manic-depressive insanity, which had terminated in post-adolescence in dementia, and he had found in these cases a regressive atrophy of the reproductive organs similar to that found in 27 male cases of dementia præcox. He regarded all these types of psychoses as genetic in origin, and he referred to the two schools of thought in relation to dementia præcox: the psychogenic and physiogenic. According to Jung the primary cause is a psychological fault in function whose history can be traced back to childhood. The physiogenic theory which Sir Frederick Mott (based upon his researches) advocated presupposes an inherent germinal narrow physiological margin of normal functional capacity of the brain, and stresses, whether physiological, psychological, or pathological, may be sufficient to excite, reveal, or accelerate the disintegration of the psychic unity owing to the genetic inadequacy. He referred especially to the effect of emotional stress and mental conflict with repression of visible manifestations upon the endocrine glands, and the interrelation of the suprarenal, thyroid, reproductive organs, and brain. He considered that the influence of toxic agents *per se* in the product of the true psychoses was exaggerated. He next described the microscopic examination of the brain and reproductive organs of two interesting cases of dementia præcox:

The first case was a congenital imbecile with infantile testis and ovaries, who developed symptoms of dementia at puberty. Here there was arrest of development of the supragranular layer of pyramids of the neo-cortex, with glia proliferation. This might be correlated with the ineducability of the girl. At puberty symptoms of dementia came on, and this might be correlated with a widespread degeneration of the cells of the cortex, especially of the deeper layers of pyramids and the polymorph and infragranular layer, which Shaw Bolton conceived to be connected with the vegetative and reproductive functions.

The other case was one of acute dementia præcox occurring in a highly intellectual youth, in which there was insanity on both the maternal and paternal sides. There was a marked regressive atrophy of the testes, together with the characteristic changes in the cells of the cortex. A brother who died from bullet wound of the brain also had a similar regressive atrophy of testes. A sister suffered with manic-depressive insanity.

A dictum of Hngblings Jackson, "the last to come ontogenetically the first to go," Sir Frederick Mott thought might possibly be explained by the fact that the countless millions of cells of the cortex cerebri were developed from relatively few of the protomerite cells constituting the neural tube and primary cerebral vesicles. Therefore, if there was a germinal defective formative energy, it was this part of the nervous system which was latest developed ontogenetically and phylogenetically that would be affected either by arrest of development or by an innate lack of durability. The supragranular layer of pyramids of the neo-cortex was the latest developed, and might therefore, as in the imbecile, undergo arrest of development. As the sex instinct in adolescence matured it stimulated and energized all the cells of the body, including those of the brain; but if there was a genetic inadequacy, with a narrow physiological margin of the highest level of neurones upon which to function and maintain metabolic equilibrium, then any one of the stresses mentioned might be sufficient to cause hypofunction with suspension or suppression of the normal activities of the highest and latest developed level, and disintegration of the psychic unity.

The PRESIDENT, after expressing the cordial appreciation of the paper by members, asked whether the dictum of Hughlings Jackson, which had been amply confirmed, that the faculties or functions which came last were the first to go, could be regarded as a progressive fact—that is, as a succeeded era would the more recently developed structures assume a condition of greater stability than at present?

Dr. MENZIES pointed out what seemed to him an objection to Sir Frederick Mott's theory—namely, that the Betz cells were analogous to neo-cortex, and were of late development, phylogenetically and ontogenetically, and therefore on this reasoning ought to be affected, but were not in primary dements. Moreover, the Betz axons were not myelinated.

Dr. CARSWELL spoke of the far-reaching importance of this communication in giving a true insight into the pathology of mental disease. With regard to the remarkable fact mentioned by Sir Frederick Mott that of 10,000 Serbians in the war who had had great stress and every variety of privation only five became insane as a sequel, in the speaker's large experience among the mentally afflicted in Glasgow the incidence of insanity per annum among the industrial population in a large engineering locality was the same—namely, 5 per 10,000, even though stress and strain and indulgence in alcohol were operative there too. In districts where dwell what might be termed the sediment of the population the incidence of certifiable cases rose to 10 or 12 per 10,000. Figures such as these supported the view of those who said that for stress and strain to result in insanity there must be organic genetic defect also.

Dr. HARVEY BAIRD asked whether spermatic or ovarian extract was likely to do good in the cases referred to. In a few cases of dementia praecox he had tried it, but he could not say it was successful. Dr. MILLS asked whether the failure of the endocrine glands or the defect in the supra-marginal layers of the cortex was the greater factor in cases of dementia praecox, or were both defects correlated in the production of the condition?

Professor GEORGE ROBERTSON (Edinburgh) also warmly praised the lecturer for his contribution. He agreed that all forms of insanity appeared, at their margins, to run into one another, like the colours in the rainbow, which were not sharply demarcated but merged into the next. He was much struck by Sir Frederick Mott declaring that it was not necessarily the brain which must be investigated in these cases, reminding him of the view of the French writer Binet that the intestinal tract was largely responsible. Moreover, Bale had done a number of *post-mortem* examinations on cases dying of mental disease and found changes in the central nervous system which he regarded as the cause of the mental condition. He discussed the paper in some detail.

Sir FREDERICK MOTT, in reply, said the Betz cells, as shown by their myelination, were ontogenetically of earlier development than was the rest of the cortex. There was myelination in all the projection centres, and the sensory-motor cells must be myelinated before the association cells, as it was only at birth that an individual could have a simple sensation; later these were linked up with perceptions. In the dog's brain myelination was more developed in ten days than in the human brain in three months. It must be remembered that a cell nourished itself, it was not nourished; therefore he did not expect improvement in dementia praecox from the giving of extracts. If any were at all hopeful it would be thyroid, because the thyroid secretion originally went into the alimentary canal, and therefore it could be absorbed. Moreover, when extracts were given by the mouth, it was not definitely known what happened to them; therefore it would seem to be wiser to give them by the rectum or the vagina. The typical form of the disease under discussion was dementia simplex—loss of mind—and that he associated with degeneration of the nerve cell which was beyond repair; though many symptoms depending on hypofunction might get better.

The PRESIDENT reminded the members of the great debt the Medico-Psychological Association had already been under to Sir Frederick Mott for his various important contributions, and referred to the effect it would have upon the teaching of psychiatry, as well as on its practice. Sir Frederick was heartily thanked.

The Maudsley Lecture.

On the same day members attended at the County Hall, Spring Gardens, to hear Sir Maurice Craig deliver the Third Maudsley Lecture, the subject being "Some aspects of education and training in relation to mental disorder."

COLLAPSE THERAPY IN PULMONARY TUBERCULOSIS.

A MEETING of the Aberdeen Medico-Chirurgical Society was held in the society's hall on the evening of June 1st, with the President, Dr. SCOTT RIDDELL, in the chair, when Dr. J. M. JOHNSTONE, of Tor-na-Dee Sanatorium, read a paper on "Collapse therapy in the treatment of pulmonary tuberculosis." He explained that the main principle involved was the production of rest of a diseased lung by immobilization, and showed how the condition of collapse favoured healing by the growth of fibrous tissue, by hindering spread of the disease, by eliminating mixed infection and stopping toxæmia. After sketching the history of artificial pneumothorax he discussed the indications and contraindications in detail. He laid it down that the ideal case for pneumothorax would be one with moderate or advanced unilateral disease which had failed to respond to sanatorium treatment in a reasonable time, but that, in practice, a small active lesion or a larger quiescent lesion in the opposite lung was not an absolute contraindication. He questioned the wisdom of producing collapse in the very early stages of the disease on the ground that cure was not unlikely by other less drastic means in a shorter time, and whilst he agreed that pneumothorax might sometimes be advisable in advanced bilateral disease for the relief of symptoms it must be looked upon as palliative rather than curative. For curative pneumothorax about 5 per cent. of the general run of cases were suitable, but in only 60 to 70 per cent. of these cases could pneumothorax be successfully induced. After referring to the treatment of hæmoptysis, pleurisy with or without effusion, and spontaneous pneumothorax by pneumothorax and gas replacement methods, he briefly discussed the question of how long the lung must be kept collapsed in different types of cases to allow healing to occur. Dr. Johnstone strongly advocated x-ray control of artificial pneumothorax treatment, especially during the induction stage. He summarized the published statistics of the general results of pneumothorax treatment and read notes of a number of cases, successful and unsuccessful, treated at Tor-na-Dee Sanatorium. Lastly, he described the operative measures which had been advocated and utilized to produce partial or complete collapse of a lung, both as alternatives or supplements to artificial pneumothorax and when pneumothorax had failed. The methods of severing adhesions preventing complete pneumothorax, the uses of phrenicotomy, extra-pleural pneumolysis, partial and complete thoracoplasty, and extra-pleural pneumothorax, were all reviewed, and cases of paraffin replacement of the upper lobe and Saugman's thoracoplastic operation were described. It was urged that all these operations could be, and should be, done under local anaesthesia in order to prevent swamping the opposite lung with discharges.

Dr. JAMES LAWSON, of Tor-na-Dee Sanatorium, dealt with the technique of the operation of artificial pneumothorax and the conduct of such a case. He described the Pearson-Lillingston apparatus and the conduct of the initial operation, laying stress on the importance of a definitely negative manometric response as an indication that the point of the needle lay between the layers of the pleura. He pointed out how the manometer might act as a minimum pressure gauge recording merely the negative pressures of inspiration, and the needle being blocked by the visceral pleura during expiration, no oscillations occur. He showed further how deceptive negative pressures might be found in the lung when the air entry into the part punctured was restricted, and how by adding oil of peppermint to the fluid in the gas reservoir the passage of gas into the lung and air passages could be quickly detected by the patient. Attention was directed to the rise in pressure which took place in an artificial pneumothorax cavity with the change in the position of the patient from the lateral to either the dorsal or erect attitude, and how this was of importance when it was desired to re-establish a previous pressure or when excessive pressures might increase the risk of rupture of the lung, as in cases with adherent cavities. The conduct of a case he divided into three stages: First, that occupied in arriving at the optimum pressure or the lowest pressure at which the maximum degree of collapse could be attained, and he pointed out the absolute necessity of careful x-ray control during this period if such complications as laxity of the mediastinum were to be detected. The second stage he described as that concerned with the maintenance of the optimum pressure, and dealt

with the accumulation of fluid as the commonest complication. His experience suggested that effusions might exercise a beneficial effect, and provided satisfactory collapse could be maintained such effusions were best left alone. In the event, however, of toxic symptoms arising referable to the fluid, frequent gas replacements and possibly lavage of the cavity would be required. The third stage was that of re-expansion, which, however, Dr. Lawson was unable to deal with fully in that paper.

A discussion then ensued, taken part in by Professor ASHLEY W. MACKINTOSH, Dr. STRUTHERS STEWART of Nordrach-on-Deo Sanatorium, Sir HENRY GRAY, Mr. ALEXANDER DON, and the PRESIDENT.

Reviews.

A HANDBOOK ON VITAMINS.

Vitamins and the Choice of Food,¹ by Mrs. PLIMMER and Professor PLIMMER, is based on a course of lectures delivered by the latter in Aberdeen, and is intended to give a short summary of the vitamin problem intelligible to the general reader. The authors have produced a very interesting book in which the important and complex problems associated with the action of vitamins are dealt with very clearly; it should be intelligible to anyone possessing a slight knowledge of physiology, and medical men will find in it much that will appeal to them.

The book deals with the general properties of the three vitamins and special attention is given to the deficiency diseases, scurvy, beri-beri, rickets, and keratomalacia. Two chapters are devoted to the effects produced by diets deficient in various amino-acids and to the relation between pellagra and qualitative deficiency in proteins. These chapters are particularly interesting and we are not aware that the information collected in them can be found elsewhere in a readily accessible form. The final chapters deal with the effects produced by partial vitamin deficiency and with the general question of errors in the choice of food. A point of special merit in the book is that full emphasis is laid on the facts that have been definitely established about vitamins, and the enormous social importance of deficiency diseases is properly insisted on.

Most of our knowledge of vitamins is recent and many interesting questions are still matters of controversy; there is always a tendency to overemphasize controversial points by devoting undue space to them, and in this way the impression may be produced that a subject is in a much more unsettled state than it really is. The authors have avoided this error very well, and bring into clear relief the enormous importance of the part that deficiency diseases have played in the history of the world. Most medical men will probably be surprised by the extent of the ravages of the deficiency diseases which this book records. Vitamins are sometimes spoken of as fads, and it is well to be reminded of the essential fact that deficiency diseases have destroyed armies and navies and have ruined empires in the past; millions of lives have been lost that could have been saved had our present knowledge been available.

One of the penalties of writing a short and readable account of a new and growing subject is that it is necessary to dogmatize upon matters that are still uncertain, or at any rate to simplify unduly problems which are really complex. The authors in this book treat rickets as a disease simply due to deficiency of vitamin A; there is no doubt that often this deficiency is an important factor in the production of rickets, but several other factors such as faulty mineral metabolism and lack of sunlight also appear to play an important part. However, it is almost impossible to produce a really readable book for non-experts in this subject, and yet to go fully into matters of controversy.

SERUM BY THE MOUTH.

Hormone Therapy by Sera, Vaccines, and Drugs,² by Dr. D. MONTGOMERIE PATON of Melbourne, is a remarkable book, whether or not the reader can agree with its contents, for it

represents the experience with the oral administration of antidiphtherial serum in various diseases by a busy practitioner during twenty-three years. It is indeed a restatement and expansion of the author's *New Serum Treatment* published in 1906, a work which we are told constitutes his claim to be the pioneer in non-specific immunity. He contends that serum contains the secretions of the ductless glands, and that these are absorbed, whereas contained antitoxins, as in antidiphtherial serum, are not, when the serum is taken by the mouth. Further, vaccines and the drugs emetine and cantharidin lead to increased secretion by the ductless glands, and thus are of use in hormone therapy. He states that when the antitoxin in antidiphtherial serum has reached 200 to 250 units per cubic centimetre the hormones in it are practically at full strength, and that antidiphtherial serum has a much more intensive recuperative power on all tissues than normal serum. In connexion with the hormone-producing power of a streptococcal vaccine it is stated that the simultaneous administration of potassium iodide "vastly widened the sphere of action, and from the results obtained it seemed to do this by the iodide restraining the action of the suprarenal glands, and so enabling the thyroid to do its work in certain directions unhampered by the opposition of the suprarenals"; this is a somewhat novel view, and the mention of "an antidiphtheria serum grown on a culture of normal serum" (p. 98) suggests a slip of the pen. But although the author's hypothesis may not be acceptable or appear to be proved, his empirical results are interesting; emetine hydrochloride is, he says, a specific for alcoholism, and has a well-marked action on the tobacco habit; thus a neurotic "cigarette fiend" entirely stopped smoking, and another was puzzled why he could only smoke 2 oz. instead of his usual 4 oz. a week.

THE ETIOLOGY OF TYPHUS FEVER.

The volume entitled *The Etiology and Pathology of Typhus*³ represents the main report of the Typhus Research Commission of the League of Red Cross Societies to Poland. It has been compiled by Dr. S. BURT WOLBACH and Dr. JOHN L. TODD, the joint heads, with Dr. FRANCIS W. PALFREY, the clinical chief of the commission, and records the clinical and pathological researches made by them during their stay in Warsaw from January to August, 1920. The book is appropriately dedicated to the memory of the investigators who contracted a fatal attack of typhus fever as the result of their researches—namely, Corneli, Cornet, Jochemann, Lüthje, von Prowazek, Ricketts, and Schüssler. In this connexion a melancholy interest attaches to the circumstance that the entomologist to the commission was Mr. A. W. BACOT, whose death from typhus on April 12th we recently had with deep regret to report.

Apart from one section devoted to clinical observations, the work deals entirely with laboratory investigations, including the study of lice in connexion with the etiology of typhus, especially as regards *Rickettsia prowazekii*, and the naked-eye and microscopical anatomy of typhus in man and guinea-pigs. In this respect the book before us offers a contrast to the work on typhus fever in Serbia by Dr. Richard Strong and his colleagues (see JOURNAL, June 11th, 1921, p. 857), in which the clinical description formed the predominating feature. The clinical studies recorded in the volume now before us were made at the chief hospital in Warsaw for typhus (St. Stanislaus) on a selected group of 181 patients (86 men and 95 women), consisting of the most typical of the severer cases admitted. The mortality was 13.25 per cent.—a low figure compared with the appalling death rate in recent epidemics in Serbia, Rumania, and Russia. The clinical description is accompanied by photographs of the eruption and of necrosis of the skin, and by numerous temperature charts; the most important clinical observations, including the age, sex, day of disease on admission, symptoms, complications, dates of defervescence and death, are set forth in tabular form at the end of the section. It is noteworthy that among 90 cases in which agglutination tests for *B. typhosus* and *B. paratyphosus* A and B were carried out by the bacteriologist, Mr. Henry Pinkerton, *B. typhosus* was agglutinated in maximum dilutions of from 1 to 200 to 1 to 1,600 in 15 cases, in maximum dilutions of 1 to 25 to 1 to 200 in 27, while 45

¹ *Vitamins and the Choice of Food*. By Violet G. Plimmer and R. H. A. Plimmer, D.Sc., Professor of Chemistry in the University of London. London: Longmans, Green and Co. 1922. (Demy 8vo. pp. xii + 161; 25 illustrations. 7s. 6s. net.)

² *Hormone Therapy by Sera, Vaccines, and Drugs*. By D. Montgomery Paton, L.R.C.P. and S. Edin. London: Baillière, Tindall, and Cox. 1922. (Fp. 163. 7s. 6d.)

³ *The Etiology and Pathology of Typhus*. Being the main report of the Typhus Research Commission of the League of Red Cross Societies to Poland. By S. Burt Wolbach, John L. Todd, and Francis W. Palfrey. Cambridge, Massachusetts: Published by the League of Red Cross Societies at the Harvard University Press, 1922. (Demy 8vo. pp. x + 22; 34 plates, 13 figures.)

gave no agglutination. A few of these patients had either had a previous attack of typhoid fever or had been given prophylactic inoculations, but in most cases of positive agglutination with the typhoid bacillus no clinical explanation was found either in the past history or in signs of a double infection, and the writers think it probable that the agglutinations were due to the peculiar propensity of typhus fever to show non-specific agglutination.

The results obtained by Mr. Pinkerton with the Weil-Felix reaction confirmed the claims made by most other workers that the test is a valuable supplement to the clinical diagnosis of typhus, and that it should form part of the routine laboratory work of every hospital receiving typhus patients. Of 83 serums from typhus cases tested only 3 failed to agglutinate *B. proteus* cultures at a dilution of 1 to 100; 56, or 67 per cent., were positive in a dilution of 1 to 800 or over; and 26, or 31 per cent., were still positive at 1 to 1,600. The highest dilution at which agglutination was obtained was 1 to 3,200. In a careful series of experiments during which they became convinced that *Rickettsia prowazeki* is the cause of typhus it was found that a variable percentage only of lice fed upon typhus patients acquire the virus of the disease, although all the lice have equal opportunities for becoming infected. Thus in the 52 feeding experiments performed *Rickettsia* were found in the louse on 27 occasions only. Micro-organisms other than *Rickettsia* did not appear in any of the feeding experiments. The writers suggest that the louse in order to become infected must pierce a capillary at the site of a lesion or localization of *Rickettsia* in the endothelium. Owing to a paratyphoid infection all but three of the monkeys sent from London to Warsaw were lost, and the animal experiments were confined to guinea-pigs. A febrile reaction of from three to nine days, discoverable only by the thermometer, was the only evidence of disease in the majority of these animals. Only three deaths occurred; they were preceded by spastic paralysis resembling that seen in rabbits. The naked-eye pathological changes in the experimental typhus of the guinea-pig are slight, but characteristic lesions are found showing the *Rickettsia* on microscopical examination.

The book contains an interesting section on the pathology of typhus in man based on 49 necropsies, only 10 of which were done later than five hours after death, so that the tissues were affected in the least degree by *post-mortem* changes. The histology of the skin was also studied in 28 specimens excised under local anaesthesia during life from cases in all steps of the disease. These studies confirmed the work of previous observers, notably Fraenkel, Jaffé, and Ceeleu, who showed that typhus is a disease of the smaller blood vessels, the characteristic lesion or "nodulo" being caused by a proliferative reaction of the endothelium and neuroglia to the *Rickettsia prowazeki*, which is localized almost exclusively in the vascular endothelium.

A bibliography of recent work on the etiology and pathology of typhus fever is followed by a large number of beautifully executed microphotographs showing *Rickettsia* in the organs of lice, guinea-pigs, and man, typhus nodules, and other lesions. The work forms a valuable addition to the literature of typhus fever, and will be read with interest by the clinician as well as by the pathologist.

GUYS' HOSPITAL REPORTS.

THE second of the four quarterly parts of vol. lxxi of the *Guy's Hospital Reports*⁴ opens with the second and concluding part of Sir Charles Symonds's historical appreciation of Sir Astley Cooper, who, like John Hunter, was not in any hurry to publish his work, and made it a rule never to make any statement not verified by his own observation. This article, which is full of interesting detail, is followed by a symposium on Addison's (pernicious) anaemia, which took place at the Guy's Hospital Research Club on January 12th, 1921; it reports the remarks of nine speakers; in his introductory note Sir William Hale-White recalls the additions to our knowledge of the disease since Addison's description in 1849. Twenty-three years later Biermer published his work and called the disease "pernicious anaemia," but, as Dr. Hurst pointed out, "beyond the pernicious name he invented,

Biermer added little but confusion to our knowledge of the subject." The condition of the gastric juice is considered in several of the contributions; free hydrochloric acid was absent in all the Guy's cases, and Dr. Hurst believes that the infection responsible for the haemolytic toxin cannot take place unless hydrochloric acid is completely absent from the gastric contents; he emphasizes the importance of giving large quantities of hydrochloric acid during the quiescent periods and in cases of apparent cure for the remainder of the patient's life. Mr. E. W. Bowtell's account of the blood has a refreshing air of personal observation and of independence.

The late results of operation in 190 cases of gastric and duodenal ulcer at Guy's between the years 1910 and 1915 are described by Dr. J. J. Conybeare, medical registrar, who finds that out of 150 gastro-jejunostomies 65 per cent. were cured or much improved, whereas only one-sixth of the cases of simple excision of the ulcer were really satisfactory. Dr. A. F. Hurst records two cases of syphilis of the stomach, Mr. W. H. Ogilvie reports spontaneous rupture of the splenic vein in a case of enlarged liver and spleen, Mr. W. M. Mollison writes on the frequency of antral infection in children, and Mr. C. Gill-Carey describes cases of septicæmia in obit media and its complications. A valuable and specially interesting feature in this instalment is the continuation of Dr. G. W. Nicholson's "Studies on tumour formation," in which he deals with tissue malformations and anomalies of bulk and of differentiation.

AN ANTHOLOGY OF HARDY.

MRS. HENRY HEAD has done a service to several sorts of people in bringing together into a volume entitled *Pages from the Works of Thomas Hardy* an anthology of his writings in prose and verse: First, to the convinced Hardyite, who will applaud her choice or deplore her omissions according to his humour, but will, as the preface suggests, be able to carry this volume with him when forced to leave the well-worn volumes on the shelf and "travel light." Secondly, it will encourage those, more numerous perhaps than Mrs. Head may think, who are frightened by Hardy—by the relentless clearness of his vision. Thirdly, it will send some to read the novels and poems who as yet know them not.

The literary judgement of contemporaries has very often proved mistaken, but it is difficult not to believe those who tell us that future generations will recognize in Hardy one of the great men of English literature. In a few sentences of penetrating analysis Dr. Henry Head in his preface shows reason for the promise of immortality. "Hardy's writings," he says, satisfy the postulate that "what we call Nature is the personification of a series of physical events of which man is an integral part. If he is to survive with any approach to happiness, he must maintain his existence by adapting himself in mind and body to forces that are indifferent to his welfare. . . . To Hardy, fate is not the wrath of a righteous Deity nor the ill-omened consequence of some outraged social custom; it is a sequence of natural events, which are neither malevolent nor well-intentioned, but simply indifferent." "Often," Dr. Head continues, the dice in one of Hardy's stories "seem loaded against the victim. . . . But more careful analysis shows that some human failure in adaptation, due to hereditary or temperamental idiosyncrasy, has contributed to render these indifferent forces effective."

Mrs. Head has classified her extracts under six heads, and, save to those who are thoroughly familiar with Hardy, her anthology will perhaps give a better idea of Hardy's message than desultory reading of his books. It may be hoped that the ultimate effect will be to send many who do not know him well to the books themselves.

SANITATION IN INDIA.

THE fact that a third edition is already required is the best proof that in this book, *Sanitation in India*,⁵ Drs. TURNER and GOLDSMITH have supplied a want. The first, published in January, 1914, and reviewed in our columns on May 30th in that year, was exhausted in less than two years; the second, issued in February, 1917, was sold out early in 1921. Dr. Goldsmith, joint author, died in December, 1919. In this

⁴ *Pages from the Works of Thomas Hardy*. Arranged by Ruth Head, with an introduction by Henry Head, M.D., F.R.S. London: Chatto and Windus, 1922. (Cr. 8vo, pp. x + 243. 7s. 6d. net.)
⁵ *Sanitation in India*. By J. A. Turner, C.I.E., M.D., D.P.H., and B. K. Goldsmith, M.B., D.P.H.; with contributions by S. C. Hormusji, K. H. Shroff, and L. Godinho. Third edition. Bombay: The Times of India, 1922. (Demy 8vo, pp. xiv + 1133; illustrated.) Rs. 15 (£1).

⁴ *Guy's Hospital Reports*, vol. lxxi (vol. II, Fourth Series), No. 2, April, 1922. Edited by Arthur F. Hurst, M.D. Issued quarterly. London: Henry Frowde and Hodder and Stoughton. (Pb. 112; 22 illustrations. Price: Subscription, 2 guineas post free for volume of four numbers; single numbers, 12s. 6d.)

third edition the sections on water, plague, tuberculosis, leprosy, and influenza have been rewritten, and much fresh material added elsewhere. The book is copiously illustrated, the type and general get-up are good, and there are few misprints. A number of Indian sanitary acts and regulations, useful for reference, are given at full length, and it should be said that untranslated vernacular terms occur frequently.

We note a few errors that might be corrected in any future edition. On page 316 appears what may be called a singular understatement: "In India the great rivers (Ganges, Mahanudi, etc.) are *several miles long*, and the current is so slow that the water takes *several days* to drift from the source to the sea." (Italics are ours.) Surely *hundreds* must have been omitted before *miles*, and *days* should be *weeks*. The Indus is 1,802 miles long, the Ganges 1,557, the Mahanudi 502. Dr. R. H. Firth, I.M.S. (p. 432), is Colonel Sir R. H. Firth, late R.A.M.C. The *late* Lieut.-Colonel W. Morris, R.A.M.C. (p. 143), is shown as living in the *Army List*. On page 85 it is said that "oored and mung (pulses) belong to the same class as grass—viz., the bean tribe." While pulses are leguminosae (beans), grasses are gramineae, a natural order far removed from the former. On page 672 it is stated that antitoxin has been proposed as a remedy for tetanus, and that in the future some efficient way of protecting the system (from tetanus) may become available. Surely the extensive and successful use of antitetanus toxin during the recent war deserves fuller and less qualified recognition.

NOTES ON BOOKS.

JUDGED by his latest book, *The Edge of the Jungle*, Mr. WILLIAM BEEBE is to be reckoned a naturalist of the school of Fabre, but, as he truly says, there is no reason why the same man should not employ at one time the latest laboratory methods in entomology—they are in the main anatomical—at another time devote himself to the observation of habits—which may be reckoned a kind of physiology—and at yet another be a systematist. Mr. Beebe in one morning can be all these. As an observer he is both venturesome and patient; he has some astonishing stories to tell, and tells them very well, only occasionally lapsing into a vague brilliancy which may perhaps be the best way to give a picture of tropic life so swift and exuberant that the observer's brain becomes fatigued by the too rapid succession of impressions. Of many of the events he saw and records he admits that he is baffled even to suggest an explanation that commends itself to human reason; but unlike Fabre he remains a good evolutionist, finding comfort in the immensity of the time the physicists are now willing to grant. The book may be heartily commended both to the general reader and to the home-staying naturalist who is not afraid to realize how diverse are the facts that have to be brought into some general scheme.

It is now thirty-eight years since Dr. Mitchell Bruce wrote his small handbook on *Materia Medica and Therapeutics*. Since that time edition after edition has appeared and been reprinted, testifying to the high regard in which this work has been held by practitioners and by generations of medical students. When the eleventh edition was published in 1918, under the joint authorship of Dr. MITCHELL BRUCE and Dr. WALTER DILLING, important changes had been made in the *British Pharmacopoeia* to meet the difficulties due to war restrictions, and those temporary modifications had to be taken into account in revising the manual. In the same way the authors, in preparing the twelfth edition, have now had to take note of the removal of war restrictions. They have not, however, contented themselves with merely recording a return to more normal conditions, but have revised the work thoroughly. Several sections have been recast and much new matter has been included in order to keep pace with the progress of pharmacology and therapeutics. Moreover, new sections have been added on balneology and mineral waters, and on invalid diet. These two additions will, we feel sure, be welcomed by those for whom the book is intended. It is a commonplace that on both subjects the newly qualified practitioner is, as a rule, painfully ignorant; the brief outline here given should do something to guide him, and will at least serve to indicate the importance of these matters in practical therapeutics. In other respects the general plan and scope of the work remain much as before, and we are glad to see that its size has grown little with the passing years.

It is by no means certain that any good can be gained by writing books against spiritualism. If such books are written, it may be that the best line of attack is through ridicule of the absurdities of the cult. Mr. SUMMERS in his pamphlet *The Fallacies of Spiritualism*⁹ takes the matter seriously. There are, however, some good stories in his book, such as that of the "spirit" of Dante and the language he used when he trod upon some tints which had been scattered about the floor. After quoting passages from the works of prominent exponents of spiritualism in which descriptions are given of the spirit world where whisky and soda and cigars are procurable, Mr. Summers mentions the amusing fact that in Miss Estelle Stead's heaven most of the spirits are "khaki heroes," though before the war they may have been stone-masons or draper's assistants. Relapsing into seriousness, he suggests that the medium through whom the "khaki heroes" speak is the "victim of tricks of telepathy and hypnotism—two of the most uncontrollable of psychic forces known to men." Then we have the story of the spirit photographed by Professor Charles Riebet, who was asked to breathe into a vessel of lime-water, which at once became turbid! After referring to the uselessness of clairvoyance, the dangers of hypnotism, and the dangers of spiritualism, Mr. Summers concludes with a chapter entitled "Where are we?" From this it appears that, in the words of Professor Jastrow, "spirit manifestations are traceable to reactions of the subconscious mind in highly keyed and nervous personalities." The book concludes with a quotation from Professor Huxley: "The only good that I can see in the demonstration of spiritualism is to furnish an additional argument against suicide. Better live a crossing sweeper than die and be made to talk twaddle by a medium bled at a guinea a séance."

The book on gynaecological surgery by R. PROUST and J. CHARRIER¹⁰ is a convenient little volume. It is abundantly illustrated, there are 283 figures, and though the illustrations are, of course, quite small and may not conform to the highest canons of art, they are thoroughly serviceable, and illustrate the verbal descriptions in an adequate manner. To those who read French with facility the little book can be recommended as an admirable compendium of the subject, most suited perhaps to the needs of men revising for a higher examination. It is very helpful in varying degree to all who are
The reviewer has not had the pleasure of seeing this little book before, but he is not surprised to know that this is the fifth edition in eighteen years.

⁹ *The Fallacies of Spiritualism. A Survey of Recent Claims and Pretensions.* By A. Leonard Summers. London: A. M. Philpot, Ltd. 1922. (Cr. 8vo, pp. 73. 2s. 6d. net.)

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on May 9th, 25 cases were considered and £374 voted to 22 applicants. The following is a summary of some of the cases relieved:

Daughter, aged 55, of M.R.C.S. who died in 1830. She is a trained nurse and worked for over thirty years, but has had to give up owing to rheumatoid arthritis; her only income is 7s. 6d. a week from insurance and a grant from the National Fund for Nurses. Voted £18 in three instalments.

M.B., C.M.Edin., aged 72, who practised in North London. Owing to overwork during the war his health suffered, and after a serious attack of influenza had general eczema. Applicant has had very little work to do the last two years; three children helped to support him, but owing to

money received from the practice was £100 per annum. The third daughter is an apothecary's week for her keep. Rent of the flat amounts to £35. a week. The Fund has granted £20; this has been paid to the Royal Medical Benevolent Fund Guild, which is supplementing it.

Daughter, aged 59, of a doctor who died in 1870. Three sisters live together in one room, one an invalid. The eldest had to give up house-keeping owing to ill health, and the second earned a little money by nursing. The second sister receives a grant from the Fund of £13 in twelve instalments, and the Fund has granted the applicant £18 in twelve instalments and a special grant of £5.

Daughter, aged 25, of M.R.C.S. Eng. who died in 1936. Applicant has been invalid ever since the death of her father, and is entirely without means. Relieved five times, £31. Granted £25 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, K.B.E., C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1. The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessities, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for secondhand clothes and household articles for the benefit of the widows and children who in happier times would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

passing years.

CONGRESS OF RADIOLOGY AND PHYSIOTHERAPY.

The first bilingual Congress of Radiology and Physiotherapy was held in London, at the house of the Royal Society of Medicine, from June 7th to 10th. It was organized by the Section of Electrotherapeutics of the Royal Society of Medicine and the British Association for the Advancement of Radiology and Physiotherapy with a view to facilitating the interchange of knowledge and experience between British workers in radiological science and their French and Belgian colleagues. The President of the Congress was Sir Humphry Rolleston, K.C.B., and the three Sections, devoted respectively to Radiology, Electrology, and Physiotherapy, were presided over by Mr. Thurstan Holland, Dr. E. P. Chamberbatch, and Dr. J. B. Mennell. The largest Section was that of Radiology, which discussed only two subjects, but had a crowded attendance and much animated debate during the whole of its five sessions. In addition to the ordinary meetings of the Sections, special demonstrations were given in departments of various hospitals, and visits were paid to the Physical Training College and to other centres. An exhibition of x-ray and electrical apparatus was held at Surrey House, Marble Arch, in which all the leading British firms in this specialized industry were represented.

Sir HUMPHRY ROLLESTON, in opening the Congress, referred to the death of many British pioneers since the last international gathering of radiologists in London, which was in association with the International Congress of Medicine. He mentioned Silvanus Thompson, Samuel Sloan, James Mackenzie Davidson, William Deane Butcher, Henry Lewis Jones, Cecil Lyster, and William Ironside Bruce, the two last named being victims of their own devotion. He then proceeded to welcome the distinguished foreign visitors, mentioning Professor J. Bergonié of Bordeaux, Drs. Konrad and Bourguignon of Paris, Professor Gommaerts of Ghent, and Dr. Gunzberg of Antwerp.

The Normal Stomach.

The whole of the first day in the Section of Radiology was devoted to the discussion of the normal and abnormal stomach as studied by x rays. The discussion was opened by Dr. A. E. BARCLAY, who exhibited some ingenious models reconstructing the actual shape of the normal stomach from the shadows seen in the x-ray room. The normal stomach, he said, was an extremely elusive thing, or rather the conception of it was extremely difficult to formulate. The stomach might vary within very wide limits, and yet be perfectly normal. It was not a cast-iron retort, but one of the most flexible and sensitive muscles in the body. A normal stomach could alter its shape and size without becoming an abnormal organ. The tonic action which played so important a part in varying the appearance was, from the radiological point of view, an entirely automatic contraction of the muscle which compensated for and counteracted the effect of gravity on the stomach contents. He referred in particular to the action of the fibres of the inner oblique coat of the stomach, which were a continuation of the circular fibres of the oesophagus, spreading out in fan shape and intermingling with and disappearing in the circular and longitudinal fibres in the lower half of the stomach. There was now sufficient evidence to suggest strongly that the function and control of these powerful oblique bands were independent of the control of the other coats, and he believed these fibres to be the cause of a certain picture of the normal stomach which had puzzled him for years, and to which he gave the name of "cup and spill," the food collecting in the upper part of the stomach in a "cup" and spilling over into the lower part.

This type of stomach was referred to by other speakers, and Mr. G. JEFFERSON exhibited some beautiful illustrations of the layers of stomach muscle—circular, horizontal, and oblique—bearing out what Dr. Barclay had said. Dr. DOUGLAS WEBSTER preferred to call it the "cascade" stomach, and said that it appeared from literature that both the "hour-glass" and the "cascade" had intermittent as well as persistent forms, and that the condition might be due either to an ulcer or to a nervous or remote cause. Mr. A. M. CONNELL mentioned a case which seemed to suggest that the "cup and spill" stomach might be caused by traction on the oesophagus, with which the oblique fibres were continuous. Dr. PEREMANS of Antwerp pointed out that the stomach, when barium-filled, differed in many respects from the normal stomach of the textbooks, and that it was

possible that the radiological stomach was itself to some extent artificial. The problem was summed up by Dr. GILBERT SCOTT, who declared that it was as difficult to describe the normal stomach as to describe the normal face. The stomach had certain characteristic expressions—he instanced the "hungry" stomach, the "slack" stomach, and the "exhausted" stomach. The emptying rate was of no diagnostic value whatever, for the "hungry" stomach might empty in an hour.

Methods of Stomach Examination.

Two schools of practice made themselves heard in the discussion on the best methods of examination of the stomach, the one suggesting that the screen view alone was of value, and the other that the screen was of less importance than the plate. Sir ARTHUR REID considered that the ideal examination would consist in exhaustive screen work supplemented by radiographs when necessary to verify the points which the radiologist had already elicited. He admitted that plate work was not so meticulously accurate as work with the screen, but the statistics of a large number of cases, not specially selected, showed that it was reasonably efficacious, and it had the advantage of exposing the radiologist to less danger. Dr. GILBERT SCOTT advocated palpation under the screen, a method which he had found to yield the most consistently correct results in diagnosis. It was true that the plate would show a gross lesion or an ulcer of fair size, but the test of any technique was the detection of the very small gastric ulcers, and these, if they happened to be on the anterior or posterior surface of the stomach, were missed by the plate. The precautions to be observed were that the screen must be at least 30 in. from the tube, that the minimum current must be used (ordinarily not more than 1 or 2 milliamperes), and that the examination must be carried through as quickly as possible. A quick examination, taking not more than five minutes, was possible if it was undertaken systematically, inch by inch. Formerly he was in the habit of paying attention to the clinical history of the patients, but now he found it better to start without any information so as to avoid bias. Too much reliance was apt to be placed on the emptying of the stomach; in the normal stomach it was possible to find a difference of four hours in the emptying rate as the result of a variation of diet alone.

Dr. G. E. VILVANDRE agreed as to the value of palpation, but said that it had to be carried out in a very limited field. It was of no use to place the hand over the smaller curvature and declare that there was no ulcer. If careful palpation were carried out all around the curvature, a point would be found at which the patient had definite pain. Mr. J. M. REDDING did not allow himself to be influenced by what he saw on the screen unless it was substantiated by radiograms. He believed that the very smallest lesion, given a certain amount of good fortune, could be demonstrated on the plate. The statement that any one area of the stomach or duodenum presented localized tenderness was fallacious in the great majority of cases. The complete insensibility of the stomach was sufficiently apparent in operations on the abdominal wall under local anaesthesia. Such painful sensations as occurred in the stomach were, he agreed with Dr. Hurst, the result of increased tension of the muscular coat. If true visceral pain did occur as the result of pressure, it was obvious that it would be produced by such pressure as would bring about the natural increase of tension—that is to say, pressure by the flat of both hands over the whole surface of the viscus, and not pressure applied to one small area. Only in exceptional cases was it justifiable to associate the epigastric tenderness with any particular area of the underlying organ.

Dr. A. E. BARCLAY advocated palpation, which, however, must be carefully done, and the palpating hand should be behind the shadow of the diaphragm. The serial-plate method, however, was preferable to the screen in the examination of the last few inches of the lesser curvature. He drew attention to one disability among x-ray workers who undertook long screen examinations—namely, diarrhoea—but by the use of an apron, back as well as front, he had found this trouble disappear entirely.

Dr. LEONARD ROWDEN said that the ulcers of the stomach which were most likely to be missed were those near the cardiac end, and he found a better view of the cardiac end obtainable by having the patient in the horizontal position when the meal was given. He always gave a full meal, and preferred to make his palpation towards the end of the emptying rather than at its beginning. He had given up the double meal method, finding the single meal serve his

purpose. By watching the peristaltic waves, viewed from the back of the patient who was lying prone, he had been able sometimes to detect a break in the peristalsis which was significant of malignant disease of the stomach.

Dr. E. I. SPRINGS said that whether or not pain on palpation was indicative of ulcer, the converse was certainly not true; he knew from cases within his experience that absence of pain on palpation did not exclude ulcer. The most effective protection to the radiologist was to spend some hours each day in the open air. Dr. C. W. SABERTON referred to abnormalities of the stomach due to reflex irritation. Frequently the appendix caused a spasmodic condition of the duodenum or an icusura on the greater curvature, where there was no evidence of any organic disease in the way of an ulcer crater. The detection of duodenal ulcers was as difficult as it had always been, and he was never sure of such an ulcer from direct evidence. Dr. G. B. BATTEN drew attention to the distortion which was possible if radiography was carried out with the patient lying on his back. Dr. MAURICE HAYES said that for fifteen years he had devoted himself to x-ray work, including a great deal of palpation, and had escaped all injury. He did the gross palpation with the gloved hand, and the detailed palpation without any rays at all, following this up, where necessary, by palpation with the naked hand under the screen.

Mr. THURSTAN HOLLAND from the chair summed up the discussion, and urged the necessity in all doubtful cases of studying the meal right through the whole intestine, and of keeping in mind the possibility of some reflex cause for the doubtful symptoms.

Deep-seated Radiotherapy.

Three sessions of the Section, covering two days, were occupied with a discussion on deep therapy with x rays and radium. The German systems, particularly the Erlangen technique, found critics and supporters. Dr. CASEMAN of Antwerp, who opened, gave a description of the Dessauer system of deep-seated therapy which he followed.

Dr. ROBERT KNOX gave an account of the technique devised by the Electrotherapeutic Department at the Cancer Hospital, the outcome of which had been the construction at first of two rotating tubes whose beams converged at a point beneath the skin, and later the construction of a rotating table with fixed tubes, the idea being by one or other kind of movement to get the penetrating radiations over the entire area concerned. Dr. GILBERT SCOTT thought that radiologists should take a broader view of cancer. It was not sufficient to treat the primary growth. The larger the area irradiated the better, not only because this procedure would influence any isolated cells, but also because the amount of scattered radiation would be increased.

Dr. VILVANDER described a visit to the Freiburg clinic, where, he said, the work was very thorough and scientific, and the microscope was brought in to assist diagnosis. He did not think that British radiologists could do better than follow the German example in the matter of deep therapy, and he begged radiologists not to be diverted from the path of pure science by national pride or prejudice. Professor SIDNEY RUSS discussed the subject from the physical point of view, and stated the problem as being one which consisted of three variables—namely, the radiation itself, the sensibility of the tumour, and the body resistance.

Dr. N. S. FINZI urged the need for high voltages in treatment. Intensive radiotherapy in future would not be a question of 200 or 300 kilovolts, but of 1,000 kilovolts. When it was possible to get radiations of that order radiotherapy would become much simpler and more accurate, as well as more efficacious. Two main methods were at present being followed in Germany. One of these was the Erlangen technique, which consisted of the use of a fairly large number of small fields, and the other was the Dessauer method, in which very large fields were used. The small field method demanded very great personal accuracy, but the other method had the disadvantage that so very large a total area of tissue was exposed to the maximum radiations. In Dr. Finzi's opinion surgery would become more and more associated with x-ray treatment in the case of carcinomas, but the x-ray applications would come first, and the surgeon's knife afterwards, an interval of perhaps several weeks separating the two procedures, and then, if the surgeon found no cancer cells, he was not entitled to say that there had never been any! The discussion was continued by a number of other speakers, one or two of whom reserved their more

considered remarks for the discussion on the same subject which is to take place in the appropriate Section at the Glasgow meeting.

Radium.

A number of interesting communications were made on the special subject of radium applications in deep-seated cancers. Mr. SAMUEL HANDLEY made some suggestions with regard to the disposition of buried radium tubes, which he thought should be placed in a ring just outside—not inside—the visible focus, thereby giving a lethal dose to the microscopic growing edge of infection, which, after all, was the important thing in the development of the growth. Beyond the remotest visible nodule of the disease there was a growing edge, permeating the lymphatics; and he believed that radiologists generally had concentrated too much attention upon the visible manifestations of the disease and not sufficient upon the microscopic extensions. It was perhaps also insufficiently recognized that in such cases as breast cancer the plane of spread of the disease was in the deep fascia and not in the skin, although it was in the skin that the nodules were seen. This meant that the lethal dose of radiation must be conveyed, not to the skin, but to the fascia at a depth beneath the skin which might, in the case of a stout person, amount to more than an inch. In malignant disease of the mediastinum Mr. Handley thought the future would show that extensive surgical procedures might be necessary and advisable in order to get the radium tubes into the best possible positions within the thorax.

Mr. HARWARD PINCH, of the Radium Institute, defined deep radium therapy as a therapeutic procedure with radium, either in the form of salts or emanations, used with a screen of not less than 1 mm. of thickness of silver or its equivalent in some other heavy metal. Deep radium therapy could be carried out by the external application of a heavily screened surface applicator, or the insertion of buried radium salt or emanation tubes into the growth, or by a combination of these two methods. The use of surface applicators was not ideal, because with these not more than 50 per cent. of the gamma radiation was made available, but there were certain situations in which external application was either obligatory, as in subcutaneous lesions, or in which it was advisable, as in malignant disease of the thyroid. He believed that as time went on surgical procedure would often be called into play to assist radium treatment. In a growth not exceeding 3 cm. in diameter the best results were obtained from burying one tube of radium of suitable size and shape. If the growth was much larger or flatter several tubes might be scattered throughout its extent at a distance of about 3 cm. apart. The two methods were combined by the use of buried tubes in the primary focus and an irradiation of the efferent vessels and lymphatics with the surface applicators. He looked forward to the use of larger quantities of radium—grams instead of milligrams—and it was hoped that the Radium Institute would shortly be able to open a small nursing home in which cases could be irradiated with one or two or even up to five grams of radium bromide. Judging from animal experiments it was important that patients undergoing deep radium therapy should have a plentiful supply of vitamin B in the diet. The combination of radium with x rays would probably give better results than either agent alone. The sequelae of radium treatment included a passing nausea, which sometimes went on to vomiting, and also certain disturbances due to auto-intoxication, with a slight rise of temperature and a feeling of general malaise. Radiated tissues presented diminished resistance to bacterial infection, and there was such a thing as radium exhaustion, in which tissues long irradiated failed to respond to radium any further. At Erlangen the artificial menopause was produced in one sitting by suppression of the ovarian secretion, but there was evidence that chlorosis vulvae was conditioned by loss of the ovarian secretion, and it seemed possible that this might arise in cases so violently dealt with.

Professor W. S. LAZARUS-BARLOW agreed that the closer the two agents, x rays and radium, were kept together in treatment, not necessarily in the same hands, the better for the patient. At Middlesex Hospital a certain amount of work had been done with a large quantity of nearly five grams of radium bromide. But perhaps there was too much inclination to assume that if good results were obtained with a small quantity of radium, much better results would be obtained if a larger quantity were available. It was true that more radium was required, but not necessarily for the treatment of the individual case. He went on to refer to a number of

cases at various hospitals in which cancer of the tongue and mouth—definite squamous-celled carcinoma—had yielded to radium-treatment, so that, at any rate at present, there was no trace of the former condition. Most of these cases were treated by the introduction of very small quantities into a number of foci, the radium emanation being allowed to remain there until it decayed practically to nothing. Of the fact that cancer cells were specially radium-sensitive there could be no doubt, but he would go farther and say that if a really satisfactory treatment of malignant disease was to be established it must be because the body of the individual in which the cancer existed was able to produce some anti-substance to the cancer cells. That was really the only rational basis for hope in the treatment of malignant disease. The discussion concluded with the exhibition of some remarkable photomicrographs of cancer cells and their changes, shown by Professor DAELS of Ghent, who also described his method of burying radium deeply in the tissues.

The Re-education of Muscles.

At a joint meeting of the Sections of Electrology and Physiotherapy a discussion took place on the re-education of muscles. It was opened by Dr. P. KOURNAY, formerly chief of staff in charge of re-education at Salpêtrière, who gave a description of the exercises which he had adopted. These included a whole series of simple movements the object of which was to teach the patient to remain first on one leg and then to keep the standing position while the upper limbs performed different educative gymnastic movements. Once the standing position was acquired and the balance of the trunk in this position obtained, one proceeded to the re-education of walking, which included four cycles: (1) stability, (2) regulation of step, (3) balance during the walk, (4) the re-educated walk. He insisted that the exercises in these four cycles should be carried out in their proper order, so that each series followed the one preceding it, and became, so to speak, a corollary of the movements already performed. Nothing was more dangerous than to break the sequence of the exercises. A few simple pieces of apparatus, such as a marked carpet, the horizontal ladder, and the inclined plane, served the purpose of carrying on with greater assurance the re-education of walking. He dealt in a similar way with the re-education of the upper limb, and described certain workshops which he had organized for the wounded in which functional re-education by means of work has proved of great benefit.

Scoliosis.

In the discussion on scoliosis Mr. R. C. ELMSLIE read a paper in which he insisted on the importance of the education of the child as a factor in securing correctness of position. The child must be instructed in the sense of correctness and taught from the first how to use his muscles. Dr. TIMBERG also touched upon the importance of home exercises as distinct from those given in the gymnasium—meaning correctness of attitude while sitting in a chair at table, and so forth. Mr. McCRAE AITKEN referred to the usefulness of keeping on a plaster jacket during sleep, even after it had been abandoned during waking hours, so that the child in slumber was prevented from twisting into an unnatural position. He had used very extensively Abbott's method, but these were useless unless the child was taught from the beginning how to use his muscles. Other speakers in the discussion were Dr. DE MUXTER of Liège and Professor GOMMAERTS of Ghent.

Backache and Referred Pain.

The Section of Physiotherapy held an interesting discussion on backache and referred pain, in which papers were read by Drs. SOSNOWSKA and WETTERWALD of Paris, Dr. GUNZBERG of Antwerp, and others. Mr. EARDLEY HOLLAND, who was invited to speak on the subject from the gynaecological point of view, said that backache was often considered to be a symptom of pelvic disorder, but it was obvious that many cases which came to the gynaecologist complaining of backache had absolutely nothing wrong with the pelvic organs. The commonest variety of backache was due to sacro-iliac strain during pregnancy. During at least the last four months of pregnancy a faulty attitude was adopted. Furthermore, the sacro-iliac joints, which were said to be loosened, underwent a violent form of exercise during labour. The patient, therefore, ended with sacro-iliac strain. His practice was to treat this strain by means of a very firm belt around the iliac crest, and as the patients commonly had visceroptosis the

wearing of corsets was enjoined. Some of his colleagues also advised high heels, but heels appeared to be high enough already! Dr. J. B. MENNELL said that there was a point two inches away from the umbilicus, on the line between the umbilicus and the antero-superior spine, where deep pressure would reveal sacro-iliac strain if it existed. He believed that thousands of appendicectomies had been removed when the real trouble was not appendicitis but sacro-iliac strain. He himself had seen a number of patients from whom the appendix had been removed because of pain in the right iliac fossa, and the pain, which was unchecked by the operation, was relieved by adequate pelvic support.

High-frequency Currents.

In opening the discussion in the Section of Electrology on the physiological action of high-frequency currents, Dr. CUMBERBATCH expressed the view that high-frequency currents had some other influence on the body besides the production of heat, although, until the problem was further elucidated, he was going to continue to act on the assumption that the effects were those of heat alone. He gave an account of a number of cases successfully treated by diathermy, both by local application for surface lesions and general application in cases of high blood pressure, where, he believed, diathermy acted by reducing the viscosity of the blood. Many cases of gonococcal arthritis, at a stage not too advanced, had yielded to this method of treatment. This subject and some of the other matters discussed in this section, as also in the Section of Radiology, are on the programme of the similar Section at Glasgow.

CLOSE OF THE CONGRESS.

Sir HUMPHRY ROLLESTON, in closing the Congress, expressed the great gratitude which workers in general medicine felt for the efforts electrologists and radiologists were making to add to the volume of knowledge. It had been a great pleasure to meet a number of French and Belgian workers in this field, and he hoped that there would be a renewal of this pleasant and useful association another year.

FEDERATION OF MEDICAL AND ALLIED SERVICES.

THE annual dinner of the Federation of Medical and Allied Services was held on June 7th. Sir BERKELEY MOYNIHAN, Bt., the President, who was in the chair, said that it was the privilege of the Federation—a privilege it had created for itself—to give such assistance and counsel as it could to the Ministry of Health; but it could not properly discharge this task until two conditions were fulfilled—namely, unity in the profession, and a right relationship between the Federation and other bodies. At the present moment a wise tolerance was not everywhere displayed within the profession; views tenaciously held were not always expressed without bitterness, nor was every opportunity taken by generous utterance to bring together professional brethren who, though working on different lines, were pursuing the same end. It was natural that there should be deep and acute differences of opinion for the everyday work of every medical man was a conflict. He was ceaselessly at war with an implacable and ruthless foe, and he knew that when the enemy was overcome it was not because a syndicate had been at work nor because a committee had been sitting, but because he (the medical man) had put all that he had into the struggle. It was for this reason that medical men became individualists, and individualists were always apt to have prejudices. Prejudice was but the emotional reaction of ignorance to truth, and the sooner prejudices were got rid of the better. Forbearance and generosity were called for in the common language they used of one another. He remembered going into the church of St. George the Greater at Florence and seeing in a side chapel the tomb of Salvino degli Armati, the inventor of spectacles, with the inscription, "May God forgive him his sins!" While the work of the medical man was individual (Sir Berkeley Moynihan continued), it had a very obvious national significance. When, towards the end of last year, he heard that one of the original founders of the Federation had been summoned to the bleak and rugged North to take care of the health of the Prime Minister, he became anxious as to the effect of the Prime Minister's malady upon the Irish question, then in a critical

stage. When Louis XIV was urged by Madame de Maintenon and the clericals to put his signature to the revocation of the Edict of Nantes he stubbornly refused at first, and only gave in at the last extremity when he was driven mad by a curious molar. Perhaps Sir Squire Spriggo might add to the gaiety of the profession by writing another of his fascinating books, describing the influence of medicine upon politics. In conclusion, he hoped that the profession would by degrees develop a corporate sense of common ideals and common duties and responsibilities. He himself was always accused by his best friends of having ideals; but ideals were very good things to have lying about. Perhaps nobody ever attained his ideal; certainly the best of them never did, because they set their ideals so high. Ideals were not for attainment, but for pursuit.

The Right Hon. ROBERT MUNRO, Secretary for Scotland, who in the absence of Sir Alfred Mond responded to the toast of the Ministry of Health, said that the Ministry and the Scottish Board of Health were quite an harmonious coalition. Though they had many differences of opinion they were solved by peaceful persuasion on both sides.

Colonel NATHAN RAW, M.P., in proposing the toast of "The Federation," said that it had three objects: to discuss with all those interested in health questions the formation of a public opinion upon which action might be taken; to protect the community against ill-advised legislation; and to secure adequate representation in Parliament of those interested in health problems. The Federation now embodied three separate councils: a medical council, a council of the allied professions, and a citizens' council, the last named being presided over by Lord Islington, whose name he coupled with the toast.

LORD ISLINGTON said that the Federation now included thirty-four societies, whose total membership ran to 100,000 individuals. The citizens' council was the latest development, and represented the lay organizations. Health was a technical matter, in respect to which the community was largely unorganized, ill informed, and even misinformed. It was an imperative necessity to educate public opinion, and he hoped that the Federation would take full advantage of the medium of the press.

SIR THOMAS HARDEN proposed the health of the President and Sir Malcolm Morris, congratulating the former upon his baronetcy and the latter upon his approaching golden wedding. Both said a few words in reply.

A HALF-CENTURY OF PUBLIC HEALTH IN NORTH AMERICA.

BY

JOHN C. McVAIL, M.D., LL.D.

(Concluded from page 923.)

V.

HOUSING AND VENTILATION.

A BRIEF article on housing as a factor in health progress in the past fifty years, by Mr. Lawrence Veiller, secretary to the National Housing Association, states that whereas the slum was formerly confined to cities, especially to New York, it is now to be found everywhere, even in villages and on the prairies. The first housing Act in the States was the New York Tenement House Law of 1867.

Fifty years ago it was the practice to build working-class houses with "interior rooms" without either light or air supply excepting such as might be obtained from an adjoining room. Then came a requirement for airshafts, which as it turned out made things rather worse, for they were closed at the bottom and without means of ventilation. They were rendered illegal, and ventilation of rooms into spaces or courts made compulsory. Priory vaults, with their plagues of flies, are being displaced by water-closets, garbage is being collected, and surface and slop drainage controls the breeding of mosquitos. Overcrowding of rooms is still common, and overcrowding on site has tended to increase with the growth of cities. Central water supply has displaced shallow wells and yard pumps. The health officer is making inspections instead of waiting for complaints, and a higher standard of personal and general cleanliness is being observed.

The article, however, gives no information as to the progress being made in the providing of additional houses, nor does it say whether the municipality or the State is

undertaking the task of such provision. The explanation of Mr. Veiller's silence on the matter may probably be that America is still endeavouring to rely on private enterprise and business emulation. If so, the question occurs whether builders are receiving any kind of assurance that if they do their duty alike in plans and workmanship and reasonableness of charges, neither the State nor the municipality will rise up in competition against them. America is suffering, like this country, from a remarkable shortage in dwelling-house accommodation, and an exposition of the State or Federal policy that is being adopted in meeting the situation would be of real interest at the present time.

From the statements contained in the article on ventilation by Dr. George T. Palmer, epidemiologist, Detroit Department of Health, it is clear that American conditions differ from those in this country in two essential respects: first, the range of atmospheric temperature is much greater in America, and secondly, that in this country we still rely largely on the open fire for ventilation as well as for heating.

During the last fifty years the very word "ventilation" has changed its meaning. Formerly it covered just the provision of pure air. Now it "is the adjustment of the indoor air environment to meet the requirements of comfort, health, and efficiency." Thus defined it pays much more attention to temperature than to any other factor, and next to temperature comes humidity, though on that question there seems much more difference of opinion. The old CO₂ standard is soundly trounced by Dr. Palmer, and it was no doubt unfortunate that the establishment of CO₂ as a convenient measure of impurity had the effect on the public, and even to some degree on the professional, mind of maintaining the erroneous view that a small increase in the very minute quantity—four parts in 10,000—of that gas naturally existing in the air is in itself a menace to health. When the carbonic acid boggy began to lose its terrors, the theory of organic effluvia for a time took its place. Temperature was receiving attention by 1895, when Billings, Mitchell, and Bergey wrote that—

"The discomfort produced by crowded, ill-ventilated rooms in persons not accustomed to them is not due to excess of carbonic acid, nor to bacteria, nor in most cases to dust of any kind. The two great causes of such discomfort, though not the only ones, are excessive temperatures and unpleasant odours. Such rooms as those referred to are generally overheated, the bodies of the occupants, and, at night, the usual means of illumination contributing to this result."

Concerning standards of air supply, Dr. Palmer recalls how the principle of 30 cubic feet per person per minute came to be accepted as an approach to De Chanmont's 50 feet, based on his observations that the CO₂ measure of four parts in 10,000 could not be exceeded by more than two parts without accompanying conditions indicative of detriment to health. The experimental work of Flüge, Paul, Leonard Hill, and others in establishing modern principles is noted. The principles on which ventilation practice in America is based are set out. The use of ducts for temperature adjustment, humidification, changes in heating practice, re-circulation, the newer ventilation standards, deficiencies in existing laws and codes, and present-day ventilating needs, are discussed in a fashion which incidentally demonstrates the author's practical experience of the problems. He evidently appreciates the value of cross-ventilation by means of opening windows, on which so much reliance is placed in this country, especially for hospitals, and even for schools, though the difficulty in schools is much greater owing to the small cubic space practicable per child. But, as already mentioned, the conditions in America are so different from those in this country that the same methods are not generally applicable, though fundamental principles cannot but be identical.

INDUSTRIAL HYGIENE.

In an article on industrial hygiene by Dr. George M. Kober of New York the history of the subject is carried very far back, and the abuses that arose, especially in textile industries early in the last century, are described. In 1905, Congress of the United States established a National Committee on Child Labor, which resulted in a great deal of Federal and State legislation. Massachusetts, as seems to have been usual, had taken the lead, but it was not until 1877 that inspectors were given the right to enter factories. The first step in many States was to require the provision of fire escapes, and eventually the provision of sanitary conveniences. Seats for female workers, guards for dangerous machinery, ventilation, meal hours, prohibition of employment of women

within two or four weeks after childbirth, medical attendance for lead poisoning, hospitals for miners, and a variety of other matters came to be included in many State laws, but still without uniformity of either purpose or requirement.

Workmen's compensation has been subject to similar divergencies, but since 1914 progress has been rapid, so that laws have been enacted by forty-five States and three territories. The New York State law of 1920 covers 23 diseases, and the Ohio law of 1921 15 diseases, as against 30 in the British Acts.

A bureau of statistics of labour was created in Massachusetts so long ago as 1869, and the Federal Government followed in 1885. It has issued many valuable publications. A bureau of mines was formed in 1909-10, and whereas in 1907 6.19 per 1,000 day workers were killed by accidents, in 1918 the rate was reduced to 3.94. A children's bureau was created in 1911-12, and was placed under the Department of Labour in 1913.

The U.S. Public Health Service organized a division of industrial hygiene and sanitation in 1915, with a research laboratory. The Health Service programme includes surveys of industrial health hazards and their prevention, reports on disease prevalence and sanitary conditions, medical supervision of employees, standards of industrial hygiene, sanitation of industrial communities, co-operation with health authorities, and supervision of industrial establishments owned by the Federal Government.

Courses in Industrial Medicine.—Dr. Kober states that all medical schools which have courses in hygiene and public health also have eight to ten lectures on industrial hygiene and the more dangerous occupations. There are both undergraduate and graduate courses. Harvard in 1918 was the first institution in the world to establish a course of instruction and research leading to degrees in industrial hygiene. The courses include applied physiology of industry, air analysis, industrial toxicology, vital statistics, industrial sanitation, preventive medicine and hygiene, industrial health administration, employment management, workmen's compensation and the legal aspects of industrial disease, nutrition, industrial surgery, orthopaedic surgery, and industrial medicine. These subjects also are the first year's work for the degree of doctor of public health in industrial hygiene, a second year being devoted to an investigation upon some phase of industrial health. Hospital attendance on occupational disease is also required. A school of hygiene and public health was opened at Johns Hopkins University in 1918. The University of Pennsylvania has since 1906 laid emphasis on industrial hygiene in courses for its degree of doctor of public health. Yale began courses in 1917. Occupational disease clinics were first begun at Cornell University in 1910, and are now held at various hospitals. Work goes on also in industrial surgery and the physical reconstruction of disabled workers.

Economic Loss.—This problem of loss in industry due to lowered health conditions has been made a subject of special study by Dr. E. L. Fisk. It was calculated by a U.S. commission in 1913-15 that 30 million wage-earners lost about nine days annually through sickness. A large life insurance company found that the loss was 5.8 days for males and 6.9 for females. Dr. Fisk has gone into the question of the cost of periodic medical examination of the entire population, and estimates that it would amount to 525 million dollars. If about ten millions of the persons examined required treatment at 100 dollars a case, this repair work would cost 1,000 million dollars, or, say, roughly £200,000,000. He makes estimates of the losses from several theoretically preventable groups of diseases—tuberculosis, influenza, venereal infection, and eyestrain. The economic loss from fatal and non-fatal accidents is estimated by the Department of Labour at over 31 million dollars. All these are enormous figures, and we quote them without comment, but Dr. Kober expresses his cordial agreement with Dr. Fisk on the subject of periodic medical examination—a proposal which was brought before our own Royal Commission on the Poor Laws, but was adversely criticized in its report as being calculated to produce a nation of hypochondriacs.

Dr. Kober concludes his exhaustive and informative paper by advocating the promotion of physical education at school, and advanced military training between the ages of 18 and 20.

"When we supply our children with healthful schoolrooms and teach them the value of periodic medical inspection, of pure air, sanitary homes, proper and sufficient food, physical culture.

baths, and suitable clothing, and the importance of pure, clean lives, the lessons taught will be applied in the homes and workshops of the nation, and a very important advance in the conservation of life and efficiency in the industries will be the consequence."

The reviewer heartily agrees.

PUBLIC HEALTH NURSING.

In a sketch of the history of public health nursing, Mrs. Lavinia L. Dock, secretary to the International Council of Nurses, after references to Florence Nightingale and to the organization of district nursing in England, especially by the establishment of Queen Victoria's Jubilee Institute, goes on to describe the growth of public health nursing in the United States from 1877 onwards. It was quickly perceived that "the services of nurse and physician must be as easily obtainable by the poor as by the rich, and there must be no exclusion." In the antituberculosis movement the value of the nurse as a teacher of hygiene and sanitation was early recognized. The school nursing movement started in 1902 and spread rapidly. Employers of labour had begun to engage nurses in 1895, and in 1909 an industrial life insurance company set on foot for its policy-holders a nursing scheme which has grown to vast dimensions. In 1910 a course of training for public health nursing was established at Columbia University, and "such training is now (1920-21) given in the form of post-graduate courses, of which there are 22 offered by . . . parts of the country." At present the Rockefeller Foundation is financing an inquiry into the whole system of nursing education.

Specialism in nursing raises troublesome problems in America, as in this country, but it is recognized as, within limits, unavoidable. Controversy exists as to whether private or public control of nursing is the better; by some it is held that dual responsibility should exist, as municipal authorities are not so likely to enter on new experiments as private bodies. The rapid extension of State direction and control is, however, the most significant factor in the development of public health nursing; this is attributed largely to the influence of the war, and the American Red Cross has done much temporary financial and administrative work, which has prepared the way for the State taking full charge. The Public Health Nursing Service increased from 130 twenty years ago to 11,000 at the beginning of 1920. The national organization for public health nursing has a considerable staff, publishes a monthly magazine, and circulates much special literature. It has standing committees for public health nursing, education, organization, and reports. Sections have been . . . child hygiene, school and industrial nursing.

Certain fundamental principles of work tested by experience are now universally accepted. One is that the nurse should not work under a charitable organization, otherwise her services are limited to those below the poverty line. Another is that she should not dispense material relief, as "patients learn to look for and value such assistance rather than her own gifts of nursing, skill, and wise advice." A similar observation is sometimes made in this country with regard to gifts of milk at child clinics; the mothers come for the milk but disregard the treatment and advice. Miss Gardner is quoted as maintaining that "the work should be on as sound a financial basis as possible. All who can afford to make payment for services should do so. This usually is arranged on a sliding scale, the maximum being the cost price of the visit; and the minimum the amount possible for the poorest patients, a range usually covering from five cents to fifty or sixty." Many associations, it is stated, now offer an hourly service at full cost or more (seventy-five cents or a dollar). Another principle is that records, including various specified details, must be kept, and another that there must be no interference with religious belief; it has been found that public health work should not be carried on by a church. Co-operation is the keystone of good work, and on professional relationships with the physician Miss Gardner is quoted as saying, "The public health nurse should not diagnose, should not prescribe, should not recommend a particular doctor or a change of doctor, should not suggest a hospital to a patient without the concurrence of the doctor, and should never criticize by word or unspoken action any member of the medical profession." But regarding this Dr. Ethel C. Burnham says, "These rules appear to me too severe, and I believe that in time they may be modified, so that a nurse will not be compelled to serve under a physician who is palpably ignorant or dangerously careless."

British Medical Journal.

SATURDAY, JUNE 17TH, 1922.

THE WELSH NATIONAL MEDICAL SCHOOL.

THE South Wales newspapers announce that the Welsh School of Medicine at Cardiff is confronted by a rather serious difficulty. The University of London and the Conjoint Board of the Royal Colleges in England, acting independently but simultaneously, have notified the authorities of the School that they are unable to recognize the King Edward VII Hospital in Cardiff as providing the facilities prescribed in the case of the hospital of a medical school. This is tantamount to refusing to recognize the Welsh National Medical School as at present organized. The Faculty of Medicine of the University of Wales, it is stated, fully appreciates that so long as the recognition applied for is withheld the status of the Welsh School of Medicine must be adversely affected, the enrolment of students for the final studies much diminished, and grave hardship inflicted on those students who have already entered upon the fourth year's courses at the Welsh school.

The report presented to the Senate of the University of London as the result of an inspection of the arrangements at the hospital is to the effect that the facilities at Cardiff for teaching practical or clinical medicine are not adequate; the professor of medicine is at present the sole teacher of that subject recognized by the University of Wales; the other members of the staff in medicine are not "recognized" teachers of the University and have no duties in relation to the teaching of the students. Moreover, the professor has at his disposal so small a number of beds that they cannot, it is said, be adjudged satisfactory provision even for a limited number of students. There are no arrangements at present for special instruction either in diseases of children or in dermatology, and definite teaching appointments have not been made in the special departments of ophthalmology, oto-rhino-laryngology, and anaesthetics. With regard to surgery, it would appear from the report that the authorities have not made definite arrangements with the surgeons for the establishment of surgical dresserships to be held by students when the number of students is such as to render the dresserships under the whole-time professor insufficient. From an interview with the dean of the medical school published in the *South Wales Daily News* we gather it to be admitted that the number of beds for medicine is too small, although it was thought that it would be enough to enable the school to start. Professor Hepburn stated also that appointments in ophthalmology, oto-rhino-laryngology, and anaesthetics had actually been made, and that it is intended to appoint Dr. Alfred Howell, assistant physician to King Edward VII Hospital, Cardiff, and physician to the clinic for diseases of children at the City Lodge, to be lecturer on diseases of children, and to give clinical instruction at the City Lodge. The position has been discussed at joint meetings of the Board of the Welsh National Medical School, and of representatives of the University College of South Wales and Monmouthshire and the governors of King Edward VII Hospital. It is reported that as an outcome of these deliberations various recommendations have been made, including one to the effect that the honorary physicians of the hospital shall be recognized as university teachers. The adoption of this

recommendation will, it is stated, provide forty additional beds for instruction in medicine.

We have no doubt that the difficulty will be overcome, and probably the action of the University of London and the Conjoint Board of the Royal Colleges, though it has caused a good deal of surprise in Wales, will eventually prove to be a blessing in disguise. We suspect that the root of the trouble is that the population which a university hospital in Cardiff should serve has outgrown the capacity of the King Edward VII Hospital. It is an attractive building externally, but it is in the centre of the city on a site which cannot be materially enlarged, and that site is overcrowded. It is not for us, of course, to suggest what should be done, but we strongly suspect that the wisest course would be to reconsider the whole hospital situation in Cardiff, and perhaps find, somewhere in the outskirts of the city, a convenient site on which the additional accommodation now required could be provided, the present building being reserved for emergency cases.

THE CASE OF RONALD TRUE.

IN our issue of June 3rd we expressed the opinion that no case had been made out for not carrying into effect the sentence passed upon the convict True at the Central Criminal Court and subsequently upheld by the Court of Appeal.

Since that date the Home Secretary, acting under the powers vested in him by the Criminal Lunatics Act of 1883, has ordered the prisoner to be removed to a criminal lunatic asylum, where he will be detained during His Majesty's pleasure. The outburst of indignation which this action has excited shows that the view we took at least coincides with popular opinion. Sweeping legal subtleties aside it is clear that the average man considers that True was guilty of a brutal murder, was responsible for his acts at the time, and should suffer the full penalty of the law. Much of the indignation so widely expressed undoubtedly arises from a belief in the popular mind that improper influences have been exerted on behalf of the convict. It is freely stated that he is the offspring of a woman of social importance, and it is said that his reprieve has been brought about by assistance which a man without wealthy friends would not have been able to command. In his statement to the House of Commons on June 13th the Home Secretary explained that he acted strictly within the law and, as we gather, in accordance with the views of the judge who tried the case and of the Lord Chief Justice, who presided in the Court of Criminal Appeal. We have no hesitation in accepting his repudiation of the suggestions, so freely made, that improper motives have been operative.

If there has been any failure of justice—and this question we are not at the moment discussing—it would appear to be the fault of the law rather than of its administrators. Let us make this quite clear. We are not now dealing with the question of responsibility for crime or with the judges' answers in McNaughton's case. The present position is one which arises under Section 2 (4) of the Criminal Lunatics Act of 1883, which enacts that "in the case of a prisoner under sentence of death, if it appears to a Secretary of State, either by means of the certificate signed by two members of the Visiting Committee of the prison in which the prisoner is confined or by any other means, that there is reason to believe such prisoner to be insane, the Secretary of State shall appoint two or more legally qualified medical practitioners, and the said medical practitioners shall forthwith examine such prisoner and inquire as to his insanity, and after such examination and inquiry, such practitioners shall make a report in writing to the Secretary of State as to the

sanity of the prisoner, and they, or a majority of them, may certify in writing that he is insane." In acting upon the result of the inquiry the Home Secretary is guided by paragraph 1 of the same section, which runs: "Where a prisoner is certified in manner provided by this section to be insane, the Secretary of State may, if he thinks fit, by warrant, direct such prisoner to be removed to the asylum named in the warrant."

It would appear, therefore, that the Home Secretary was bound to order a further medical inquiry into the prisoner's state of mind, and the committee appointed for this purpose having reported that the prisoner was insane, the only question that arises is how far the Home Secretary was entitled to exercise discretion under paragraph 1. The words in that paragraph "if he thinks fit" suggest that he need not necessarily accept or act upon the opinion of the committee. On the other hand, the terms of the Act would seem to imply that if the committee finds the prisoner to be insane the Home Secretary shall cause him to be removed to a criminal lunatic asylum; if this is not the meaning of the Act there can be no point in holding the inquiry it directs shall be held.

The action of the Home Secretary from the legal point of view is accordingly not an overriding of the decisions of the Central Criminal Court and the Court of Appeal. It does not imply that True was insane either at the time he committed the crime or at the trial. The course taken is in fact that which is laid down by law to be followed when a prisoner becomes insane after conviction and while waiting for the sentence to be carried out. From the demeanour of the House it was clear that the Home Secretary had carried conviction on this point, and the motion for an adjournment did not receive the support of forty members as the rules of procedure require.

The case of Ronald True has, however, illustrated yet another unsatisfactory feature regarding insanity and the criminal law of this country. The Criminal Lunatics Act simply uses the word "insane" without any references to responsibility and without any attempt to define the word. From the medical point of view we know that it is impossible to frame a definition of insanity which shall cover all cases and exclude many who would not be regarded as insane. The *Times*, which has gone curiously wrong in its editorial comments on the case, has done a service by encouraging a correspondence to which Sir Herbert Stephen and Sir Maurice Craig have been the chief contributors; the former opened by stating the extreme legal view, saying quite definitely that some insane persons may, in spite of their insanity, be held responsible for their acts, and, if found guilty, suffer the penalty that the court may inflict. Yet the Criminal Lunatics Act would appear to provide such persons with a means of escape from their punishment.

We have already referred to the strong subcommittee which was appointed by the British Medical Association in 1913 to consider the state of the law with regard to legal responsibility for crime, and we feel more than ever now that action on the recommendations of that committee is called for.

THE ETIOLOGY OF CANCER.

THE interest the public takes in the discussion of the cause and prevention of cancer has been shown once more by a recent correspondence in the *Times*, but though among the contributors were some men of high intellectual powers and scientifically trained minds hardly any points new to the medical reader have been brought out. The fallacy of contrasting rates of mortality in different countries at different levels of statistical

accuracy and medical efficiency is well known and was not avoided by all the correspondents, but, apart from this, the testing of hypotheses not *prima facie* unreasonable is a far harder matter than any of the writers seemed to realize.

Let it be granted—and we think it may be granted—that the increased rate of mortality from malignant disease in this country is not sufficiently explained by (a) improved methods of record and diagnosis, and (b) increase of the numbers exposed to risk at vulnerable ages. The vague conclusion that increasing "civilization" is responsible is unhelpful, if logical. Some correspondents suggest that an article of diet—for example, tea—or some other substance of increased consumption, such as tobacco, may be the culprit. It clearly may, but it is very hard to devise a method of testing the assertion. The statistical association of an increasing *per caput* consumption of tea and an increasing death rate from cancer takes us hardly any way: for consumption of tea we might substitute income tax, expenditure on the navy, circulation of cheap newspapers, or any other statistical ratio which has increased over the same period. The comparison of cancer mortality rates upon smokers and non-smokers is also not demonstrative, because the habit of smoking is not distributed at random; generally speaking, the minority of a population in respect of any widespread social custom are likely to differ from the majority in more ways than one. It is, of course, not beyond the power of modern statistical methods to handle many different variables, but the provision of a very large amount of accurately recorded information is essential, information that cannot be compiled by any existing statistical department. Few of the correspondents to the *Times* seem to have realized these difficulties. Thus Mr. Hudson writes, "Statistics show that cancer only develops among persons of a highly nervous temperament," says one correspondent. Well, here is a direct challenge to the statistician. A statistician before taking up this direct challenge will probably wish to know, first, what is the definition of a highly nervous temperament, and, secondly, where statistics are to be found which prove that such persons are particularly liable to cancer.

There are indeed many lines of statistical research which can be and, we believe, are being pursued. The General Register Office has steadily improved the statistics of incidence by primary site and an examination of these data suggests various lines of fruitful investigation. Similarly, materials are accumulating for the closer analysis of occupational incidence. But the number of years over which really comparable data can be compiled is still small. Importance also attaches to the correlation of incidence of other fatal diseases and cancer, a subject upon which Maynard, Greenwood and Wood, Clairmont, Brownlee, and others, have written. There is also the geographical distribution of the disease within the same country. The general level of accuracy of diagnosis is now perhaps sufficiently high to justify such studies in England and Wales. Above all, closer co-operation between the research officers of the central departments and insurance practitioners holds out the promise of valuable clinico-statistical investigations.

But, without in the least desiring to set bounds to the possibility of advance on these lines, we believe the impulse to discovery is likely to arise in laboratories, perhaps in connexion with such researches as those mentioned by Professor Joly. Alice was told that if she wished to meet the Red Queen the best thing to do was to walk in the opposite direction. The endowment of research in general rather than cancer research in particular may be better policy than to attempt to induce men of imagination to restrict their range.

THE CONGRESS OF RADIOLOGY AND PHYSIOTHERAPY.
The Congress of Radiology and Physiotherapy arranged in conjunction with our allies of France and Belgium, which had to be postponed last year owing to the railway strike, has been held at the Royal Society of Medicine on June 7th to 10th. In addition to attracting most of the leading radiologists and electrotherapists in Great Britain many well-known French and Belgian workers attended. As was perhaps to be expected, the Section of Radiology, over which Mr. Thurstan Holland of Liverpool presided, attracted the largest audiences, but the Sections of Electrology and Physiotherapy were well attended also, and altogether the Congress was a great success. This is, we believe, the first congress of the kind which has been held in this country, and there is no doubt that the papers read and the discussions which took place will have a definite and useful influence on the three somewhat specialized departments of medicine concerned. In the Radiological Section the two subjects for consideration—namely, the normal and abnormal stomach, and deep therapy—both proved attractive, especially perhaps the latter. Much difference of opinion was manifested with regard to the claims for exact dosage in the treatment of cancer made by, or emanating from, the Erlangen clinic. Probably the general view was that a very distinct step forward had been made in the method of applying x rays to this disease, an advance which might in the future have far-reaching effects, yet it was very doubtful whether the Erlangen claim to have discovered and defined a lethal and a stimulating dose could be substantiated. Warnings came from many speakers that the time had not yet arrived when the surgeon should be thrown overboard, but that, on the contrary, surgical removal of malignant growth should remain the first method of attack; x rays and radium, as Mr. Sampson Handley pointed out, should be regarded as additional weapons, and no surgeon could afford to do without them. The proceedings of the Physiotherapy Section included a visit to the Physical Training College at Dartford, and the foreign visitors were much impressed by the work which was being carried on there. Chief amongst the discussions in this section was that on cardiac disorders opened by Professor Bergonié, and it was generally agreed that the treatment of heart conditions was not complete if the ordinary medicinal methods were not followed up by those of physiotherapy, in which graduated exercises are an important element. Perhaps the most important communication in the Electrotherapeutic Section was that of Dr. Bonrguignon, who described his own researches on muscle and nerve reactions by the chronaxie method. An international committee has been established, and it is intended that some time next year (1923) a second congress on similar lines shall be held in Paris.

HOW IT STRIKES A CONTEMPORARY.

The members of the Congress of Radiology and Physiotherapy which met last week in London could not separate without dining together. On this occasion Sir Humphry Rolleston, President of the Congress, was in the chair, and the toast to the guests was committed to Sir StClair Thomson, who, rising to the occasion, made a speech full of wit and humor, which, out of compliment to the French and Belgian members present, was delivered in French. The English, he said, had been described as a people who passed the greater part of their lives in the open air, who know no language but their own, and even in that expressed themselves with difficulty. But they had no false shame in the matter, and although they never troubled to learn the tongue of their neighbours they held open their gates and extended their hands. As he was speaking in French, and might rely upon the English portion of his audience failing to follow his remarks, he would let the visitors into a secret: he himself was not English but Scottish, and it was well known that the Scottish and the French were always in accord "*pour embêter les Anglais*." It was just because they had been neighbours of the English—the Scottish in the north and the

French in the south—that they had had to wage such fierce combat in centuries gone by, but having fought as gentlemen and not as barbarians, the conflict being over, they made the best of friends. Englishmen, *pour sang*, were too modest to act as guides to their unknown island, and therefore he would charge himself with the duty of giving some information and counsel to the visitors from abroad. If they wished to understand England they must know, not merely that its inhabitants lived on an island, but that each inhabitant was himself an island—isolated, silent, uncommunicative. If they asked a favour of an Englishman he might not respond, or might even refuse, but by stealth he would perform whatever was asked of him, and then if he were thanked for it would get angry. If they spoke to the Englishman of his climate, his relations, or his Government, he would always give the same answer—that he detested them all and always. They would find that England was administered by the Scottish, governed by the Welsh, and harassed by the Irish. That was the reason why this was called the United Kingdom! The Continental visitors had come to this country in the hope of discovering the English. He himself had been discovering the English for half a century, and finding their welcome (when he came to understand them) so very warm, he had remained until he had become himself more English than the English. The English were a people who loved to be indolent, and yet they were very hard-working; they were melancholy, and yet of great good-humour; they were a clumsy folk, and yet very much alive and awake; rude, and yet engaging; and silent, but of great sincerity. The toast was responded to by Professor Daels of Ghent, who expressed the gratitude of his Belgian colleagues for their reception in London, and their appreciation of the comradeship of science which they found here; and by Professor Bergonié of Bordeaux, who spoke feelingly of British fraternization, alike in the great cataclysm of the war and in the troubled years which had followed it. Dr. Gunzberg of Antwerp added a few words, mentioning that it was in his city, in September, 1920, that, at a gathering of French and Belgian radiologists, with a few British visitors, the idea of a bilingual Congress was projected. The healths of the President of the Congress (Sir Humphry Rolleston) and the General Secretary (Dr. Stanley Melville) were received with great enthusiasm.

THE MECHANISM OF HEREDITY.

THE Croonian Lecture delivered before the Royal Society on June 1st by Dr. T. H. Morgan, professor of experimental zoology in Columbia University, New York, dealt with the mechanism of heredity, a subject to which he has made many important contributions. He began by pointing out that the changes that take place when the germ cells ripen are known to be of such a kind that, granting the hereditary elements are carried by the chromosomes, these changes may be made to serve as a mechanism furnishing an explanation of the principles of heredity discovered by Mendel. If, he continued, the criticism were made that these facts only showed a parallelism between the chromosomes and inheritance of characters, then the following evidence could be quoted as bearing very directly on the issue. In the course of the ripening of the germ cells irregularities occurred, he said, at times in the distribution of the chromosomes. These irregularities could be followed in successive generations, and the departures from the ordinary course of inheritance there shown were found to be exactly related to the new distributions of the chromosomes. Without a detailed account of this evidence it was not possible to do more than to state that the facts furnished most convincing testimony that the Mendelian characters are carried by the chromosomes. Not only was there evidence that the chromosomes were the bearers of the hereditary elements, but, owing to a phenomenon known as "crossing-over," it was possible to determine that the hereditary elements lay in a single line in each chromosome. It was even possible to form a rough estimate of the upper limits of size of these elements;

at the present time such estimates are necessarily very crude, and are interesting only as the first attempt to determine the size of the "gene."

PHYSIOLOGICAL EFFECTS AT HIGH ALTITUDES.

IN the Friday evening discourse delivered at the Royal Institution last week Mr. Joseph Barcroft, F.R.S., Reader in Physiology at the University of Cambridge, provided some details of the recent expedition to Peru, to study physiological effects at high altitudes, supplementing the account he gave to the Chelsea Clinical Society as reported in our columns on April 22nd (p. 648). The observations were carried out in the mining town of Cerro de Paseo, which is situated in the Andes, at a height of about 14,000 feet. Mr. Barcroft noted in passing the curious fact that at 12,000 feet there were cows which gave milk, and at 13,000 feet cows which gave little or no milk; this was not a question of fodder, because fodder was brought to the animals, and still they gave no milk. At 15,000 feet there were neither cows nor milk. Another point of interest was that fleas disappeared at 11,000 feet, though the louse accompanied man to a higher region. The Andes were chosen for this expedition for two reasons. The less important was that, unlike the heights on Tenoriffe, to which the lecturer had previously gone as a member of an expedition, water was obtainable, by means of a water tower on the railway, right up to the level at which the work was done, and water, of course, was the first essential of the laboratory. The second reason was that in this case, instead of a mountain solitude, there was a community which had been acclimatized for generations to life at these levels. The people in this region were interesting ethnologically: they might loosely be called Indians, and their civilization, such as it was, probably dated back to before the days of the Incas. Many of them lived in chimneyless and windowless houses; they had a purely communal system of government, and some of their customs would hardly appeal to more civilized races. When a native was very ill, for instance, the date of his funeral was fixed without reference to his convenience, and an official saw to it that he was ready to keep the appointment! It was remarkable what loads the people were able to carry at these altitudes. A boy of about 13 would carry from the interior of a mine a burden of 40 lb., ascending a staircase with it from a point 250 ft. below, while a full-grown man would carry a hundred pounds of metal; yet the European was out of breath if he carried his coat up a slight incline. Even the native, however, only accomplishes the work with great panting and with many intervals for rest. X-ray photographs of the chests of some of the natives showed that the ribs started almost horizontally and went round the chest like the hoops of a barrel. According to tables of chest measurements in relation to the length of the spine, the natives in this region should have a chest measurement of less than 80 cm., whereas their usual chest measurement was 90 cm. The native who was 5 ft. 2 in. in height had a chest which should belong to a man of 5 ft. 11 in. Mr. Barcroft dealt also with blood changes. The immediate effect of the ascent was greatly to increase the number of red blood corpuscles, and although this excess was somewhat reduced later, the blood of members of the expedition showed throughout a larger proportion of young blood cells than normal. Comparative x-ray photographs showed also that the heart tended distinctly to become smaller. Mr. Barcroft closed by appealing for the establishment of some institute and laboratory which should continue permanently the study of the physiological effects at high altitudes.

MEDICAL SCIENCE AND THE THEATRE.

Pasteur is the title of the play with which M. Lucien Guitry, the eminent French actor, has this week opened his repertory season in London. The piece, which was played last year in London on a few occasions by M. Guitry, was first produced in Paris in 1919. It no doubt owes something to the successful production in this country of *Abraham Lincoln*, for both

plays depict a great man in selected scenes at different periods of his life. The author of *Pasteur* is M. Sacha Guitry, son of the actor, who admittedly found his inspiration in Vallery-Radot's biography of Pasteur, and designed the play especially to suit the talents of his distinguished father. The first act shows Pasteur in his study with his pupils at the outbreak of the war of 1870. In the second act there is a moving representation of a meeting of the Academy of Medicine, where Pasteur vigorously combats an attack upon his theories; in this scene the audience plays the part of the members of the Academy, with one or two actors speaking from the stalls. In the third act the boy Joseph Meister, who has been bitten by a mad dog, is brought to be inoculated by Pasteur, who sends for a doctor to perform the inoculation, for Pasteur himself held no medical qualification. The dramatist shows his art at the close of this act, for Pasteur, although he knows he can give no help, stays on all night in case something unexpected may happen. The scene changes in the fourth act to Pasteur's home in the country, where he lies ill and on the verge of a breakdown; his friend the doctor tries to persuade him to take a rest, but Pasteur is deeply engaged in the study of epilepsy and cannot tear himself away. To him comes again Joseph Meister, now a youth, and a delightfully sympathetic scene ensues between the two. The last act is the crown of Pasteur's career, his reception by the President of the Republic in the amphitheatre of the Sorbonne, crowded by his friends, among whom is Lister, whose name is announced, although he does not actually appear on the scene. The play has no "love interest" and no female character, and follows no dramatic rules; it is practically a series of monologues, in which the actual words of Pasteur are often used, and its only unity is in the portrayal of its chief character. It is a triumph for M. Lucien Guitry, who appears to live the part of the simple, unaffected, kindly man of genius. A play of very different character is announced by Mr. Bourchier for production in London at the end of this month—*Le Caducée*, by "André Pascal," a pseudonym of Baron Henri de Rothschild, who is a doctor of medicine and a philanthropist, as well as a playwright. *Le Caducée* was given with much success in Paris last year, and depicts the career of a Parisian surgeon, an unscrupulous charlatan, who sells the antiques in his consulting rooms on commission, splits fees with the doctors who send him patients, encourages the visits of reporters and photographers to his operating theatre, performs unnecessary operations and kills his patients, and at the end commits suicide. There are some thrilling scenes in the play, and one medical character, "Professor Godfroy," is well portrayed; but its whole atmosphere is extremely distasteful to anyone to whom the honour of the medical profession has a meaning at all, besides being grossly untrue to life, certainly in England, and probably also in France.

MEDICINE AND INDUSTRIAL LEGISLATION.

SIR THOMAS OLIVER, at the conference of the Royal Institute of Public Health at Plymouth, read a paper giving an account of some of the social and medical gains of industrial legislation, in the course of which he said that factory life was a unity, and the hygienic problems it presented could be satisfactorily settled only by a combination of medicine, capital, and labour. It was being suggested in the United States that each trade union should organize its own health work and conduct it with the co-operation of the Workers' Health Bureau, but he thought that in this country labour should not attempt to act single-handed, but should trust the Home Office and employers, and co-operate with the leaders of industrial hygiene, who were neither the partisans of employers nor the patrons of labour, and who were able on that account to take a wide view of industrial health problems. In the benefits it sought to bestow preventive medicine was indivisible. To split it up in the manner suggested by the trade unions of the United States would inevitably lead to the intrusion of politics. The Employers'

Liability Act, had been superseded by the Workmen's Compensation Act, whereby compensation was given for personal accidents where no one was at fault. The benefits of this Act were extended to most trades, including agricultural labourers, with the result that thirteen millions of workpeople were brought within its sphere. The object of the Act was to compensate for accidents, but, as in the courts of law the term "accident" was difficult to define, considerable difference of opinion had arisen at times as to what really constituted an accident. The coexistence of disease and accident intensified the difficulty, since where a sick person met with an accident and died from it shortly afterwards it might be a question whether death was the result of the injury or of the pre-existing illness. The trend of industrial legislation during the last half-century had been in the direction of the protection of life in occupation, the preservation of the health of the workers, and, in the case of accident and ill health traceable to occupation, the provision of compensation. There was a growing disposition to demand more and more assistance from the State, and the State unfortunately had yielded too readily to the clamour. One way by which the increasing call upon the resources of the State might be lessened would be to make each industry capable of meeting the financial claims consequent upon the death of workers. The National Insurance Act provided relief for the time being, but there was no reason why life insurance should not apply to a whole factory, so that in the case of death of any one of the workers a sum of money might be paid to the widow and children of the deceased. There were insurance offices willing to undertake the risk, and to pay £100 to a workman's dependants, in return for 6d. a week for each worker employed up to the age of 65 or 70. Such a scheme might well be contributory. "Group life insurance," as it was called, had already found favour in the United States, where it was run entirely by employers, who found in it one means of keeping the men longer attached to a factory, of diminishing labour turnover, and of creating a better feeling between employers and employed. No medical examination of workpeople was required, since they were insured *en bloc*, and the insurance office paid quite irrespectively of the cause of death. Trade unions preferred such a method of insurance as this to the granting of pensions, since to obtain a pension workers would be obliged to render at least twenty years' service in a particular factory.

A CORONER AND THE OATH.

OUR attention has been called to an inquest held recently at the Durham Workhouse, in which the medical witness asked to be sworn in the Scottish fashion. The coroner is reported to have replied: "Why on earth quibble about it on such a hot day? You are in England now, and if you don't take the oath I will either commit you or refuse to take your evidence." To a further protest the coroner replied, "Fiddle-de-dee." The medical witness then took the oath, holding the testament while the oath was administered. It would seem that the coroner was wrong in refusing to swear the witness in the Scottish fashion, for in 1893 the Home Office issued a circular to magistrates, clerks, coroners, etc., which quoted from the Oaths Act of 1888 to the effect that if any person desired to swear in the Scottish manner he should be permitted to do so without further question. There is nothing in the Oaths Act of 1909 withdrawing this right. We do not consider that the question is of much practical importance, for now that the insanitary practice of kissing the book has been abolished, the difference between the present English and the Scottish methods would, to most people, be immaterial. We must, however, record a protest against the deplorable exhibition of bad manners on the part of the coroner. In former years, when coroners were not concerned to do much more than find a verdict of death from accident, murder, or natural causes, as the case might be, the part played in an inquest by the medical witnesses was relatively small. But with growing social

development it becomes more and more important for many purposes to ascertain scientifically the precise cause of death, and to achieve this purpose close and cordial co-operation between the coroner and the medical witnesses is essential. Co-operation, however, is not promoted by such unseemly outbursts as that described above.

THE FELLOWSHIP OF MEDICINE.

THE *Bulletin* of the Fellowship of Medicine and Post-Graduate Association for June contains quotations from letters addressed to the secretary by visitors from abroad who have benefited by the post-graduate courses in London; they express their gratitude to the Fellowship and incidentally their appreciation of the courtesy and ability with which the secretary, Miss Margaret A. Willis, has discharged the duties of that office. All who are acquainted with the work of the Fellowship of Medicine and Post-Graduate Association know that Miss Willis has well deserved this praise, with which we wish to associate ourselves. One of the letters quoted is from an American graduate, who says that during a two months' visit he found the work well organized and instruction much more readily available than he had been led to believe. "The general plan is excellent. If the hospitals are a little scattered the transportation system is the best in the world. The men who give the instruction are in general of such high calibre and the instruction is on such a sound basis that I see no reason why London should not increase steadily in importance as a post-graduate centre." He goes on to express the hope that it will be possible before very long to publish a schedule for six months or a year ahead, so that men from other countries may be able to arrange their visit to the best advantage. Another letter quoted is from an Australian graduate; he considers that when all the difficulties are considered the results achieved are quite remarkable. With regard to the American graduate's suggestion that a handbook should be published, the editor of the *Bulletin* points out that the question of finance comes in, but expresses the hope that before long the financial position will permit of an advance in propaganda undertakings. We can only trust that this hope will be fulfilled.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE annual dinner of the West London Medico-Chirurgical Society was held at Princes' Restaurant, London, on June 7th, with the President, Sir George Lenthall Cheate, in the chair. After the loyal toasts had been honoured, Mr. W. McAdam Eccles proposed the toast of "The Imperial Forces," to which Lieut.-General Sir Arthur Sloggett responded. The toast of "The West London Medico-Chirurgical Society" was proposed by Sir Anthony Bowlby, P.R.C.S., and in response the President briefly summarized the history of the society, mentioning the names of the many famous physicians and surgeons who had been closely associated with it. It had, he said, always encouraged general practitioners and consultants alike, and the number of young medical men who were members had been a feature of the society from its foundation. The toast of "The Cavendish Lecturer" was proposed by Sir Arthur Keith, who welcomed Professor Harvey Cushing as a surgical ambassador from the United States to this country. In response to the toast Dr. Harvey Cushing said that at present, on the invitation of the authorities of St. Bartholomew's Hospital, he was acting for a short time as director of its surgical professional unit, returning the visit that Mr. Gask had made last year to the Brigham Hospital, Boston, U.S.A., as temporary surgeon-in-chief. Such an interchange of teachers between the medical schools of America and England was evidence of the sincere friendship which existed between the medical profession in the two countries, and had received so great an impetus from their close association in the British Expeditionary Force during. The toast of "Kindred Societies and Guests" was given by Sir Alfred Rice-Oxley, M.D., Mayor of London, who received many congratulations during the evening. The toast of "The Fellowship of Medicine" was given by Sir Alfred Rice-Oxley, M.D., Mayor of London, who received many congratulations during the evening. The toast of "The Fellowship of Medicine" was given by Sir Alfred Rice-Oxley, M.D., Mayor of London, who received many congratulations during the evening. The toast of "The Fellowship of Medicine" was given by Sir Alfred Rice-Oxley, M.D., Mayor of London, who received many congratulations during the evening.

was acknowledged by Mr. James Berry, president of the Medical Society of London, and Sir William Willeox, president of the Harveian Society. The toast of the President, given by Mr. Rickard Lloyd and acknowledged by Sir G. Lenthal Cheatlo, brought the evening to an end.

A LETTER OF EDWARD JENNER.

THE May number of the *Canadian Medical Association Journal* contains, with comments by Dr. M. E. Abbott, an interesting unpublished letter by Jenner. It is dated April 11th, 1808, and is addressed to Miss Newcome, Grosford Parsonage, near Choster. From a facsimile of the address, the mere transmission of the letter from Cheltenham to Chester appears to have cost 1s. 6d., and as Jenner's correspondence was immense, his outlay on postage must have been very heavy. Through Miss Newcome he congratulates certain ladies on the success of a vaccine campaign on which they were engaged, and replies to several questions. The vaccine mark, he says, is similar to that of the natural cowpox, but its form depends on how it was produced by the lancet; next, the security conferred by the vaccination is obtained by the eighth day if the pox has proceeded regularly up to that time. The third question, "Is it a preventivo of itself?" elicits the reply, "Not uniformly so." Both question and answer are so condensed that, in the absence of the text of the ladies' letter, the meaning is not absolutely clear, but the point appears to be whether one vaccination prevents a second. Jenner's reply may be taken to mean that he had seen cases in which it had been possible to cultivate vaccinia on the arm of a previously vaccinated subject. He does not say whether the explanation might sometimes be found in the character of the primary operation, or in lapse of time, or in individual idiosyncrasy. But he was not writing a disquisition; he was only answering a letter. A further question was, "Why is the scab the least eligible source of infection?" and the reply is that its outer edges would be formed only at a late stage—after the areola was complete—but that matter from the centre would be more likely to produce a perfect pox. After commending the ladies for the method and accuracy of their case records, and making reference to an outbreak of small-pox at Ringwood in Hampshire, Jenner answers a fifth and final question by relating a little incident which had given him much pleasure. "A fine little boy, about 6 years old, came to my house in town last spring, and presented me with a nosegay. He was accompanied by his mother. 'Pray, young gentleman, who are you?' said I. 'Edward Jenner,' said the boy. The mother then told me that his unhappy father died of the small-pox just at the time he was born, and in the same room, and that Dr. King, who attended her, vaccinated her infant at half an hour old. Thus was he shielded from the horrid pestilence that had destroyed his father. Don't you think the little urchin's bouquet smelt sweet?" Then he goes on to say that though in emergency no time is too early for vaccination, yet, when there is a choice, it may be prudent to defer the operation till the infant is a month old.

THE MEDICAL SCHOOL OF COLUMBIA UNIVERSITY, N.Y.

IN his annual report for the year 1921 the President of Columbia University, New York, Professor Nicholas Murray Butler,¹ whose numerous degrees include the Honorary LL.D. of no fewer than sixteen universities, says much that is valuable on educational problems, and particularly those of medicine. Medical teaching has become extremely costly, and indeed is, he says, the spoilt child of education. Nevertheless it is, he affirms, about half a century behind other forms of higher instruction, as a result of what may be described as the intellectual isolation of the medical pro-

fession. There is therefore, he alleges, need for a very severe critical investigation of medical teaching by a body of experts in educational processes. As long ago as 1769, in his famous Commencement Address, Dr. Samuel Bard, Professor of Practice of Medicine in King's College, New York, set the essentials of a public hospital, medical teaching, and research. The very long delay in realizing this scheme is as much as anything attributed to the feuds, jealousies and rivalries of the medical profession in New York during the last century. The President therefore considers that the most notable achievement of a notable year has been to clear the way for carrying into quick effect the project for the development of the medical school in a manner fully worthy of its opportunity. This has been rendered possible by the cordial co-operation of the Presbyterian Hospital and by generous provision, where the sum of fifteen million dollars, necessary for the successful success of this scheme, has been practically assured. The professors of clinical subjects are to be university professors in fact as well as in name, will be called on to full-time academic service, and will be provided with adequate salaries; they will come under the following statute of the University: "No officer of instruction shall be employed in any occupation which interferes with the thorough, efficient and earnest performance of the duties of his office." But the literal obligation thus implied is not to be too rigidly insisted on in practice, and the President, on whom rests the responsibility of determining when in any given case the statute may appear to be violated, takes the wise view that arbitrarily to deprive a university officer of opportunities for practical experience, even when they bring pecuniary reward, is to decrease and not to increase his scientific and educational usefulness. One of the main objects of the modern university is to keep its teachers and organizers of research from becoming too academic, too narrowly limited to their work in the university, and too remote from the outside world. In establishing full-time service for clinical professors it has not been thought necessary or advisable to adopt any of the methods, some of them fantastic and bizarre, that are understood to have been proposed elsewhere. Professor Butler points out that Columbia University has an exceptional opportunity to go forward without delay and without great expense in carrying out its plan for post-graduate courses in medicine. This attitude would not be unworthy of the sincerest form of flattery by a university within a hundred miles of South Kensington.

"PHYLLOSAN."

Forms sent out recently by the publishers of the *Medical Directory* to medical practitioners, for the purpose of correcting the entries in the forthcoming edition of the work, have been accompanied by a leaflet issued by the Chlorophyl and Chemical Corporation, Ltd., advertising the preparation known in this country as "Phyllosan." One side of this leaflet is headed "Authentic Evidence of Efficiency from the Leading Medical Press of the World," and the references given include the *BRITISH MEDICAL JOURNAL*, March 4th, 1922, but no indication is given that this is a reference to our advertisement pages and not to our editorial columns. The only editorial reference to Phyllosan that has appeared in the *BRITISH MEDICAL JOURNAL* was an article published on February 25th, 1922 (p. 317), and to this notice we would direct the attention of members of the medical profession who may possibly have been surprised by the leaflet issued by the Chlorophyl and Chemical Corporation, Ltd., in the envelopes containing the *Medical Directory* forms.

On June 4th, at the special invitation of the governors and the medical school, Professor Harvey Cushing took over the directorship of the surgical unit of St. Bartholomew's Hospital and replaced the director, Mr. Gask, for ten days. The compliment was, as it were, a return for a like compliment

¹ *Columbia Univ. Bull. of Information*, 1922, ser. xxii, No. 5, pp. 1-62, January 14th. Annual Report of the President, 1921.

paid to Mr. Gask last year, when he acted as temporary chief of the Peter Brigham Bent Hospital, Boston, to which Dr. Harvey Cushing as professor of surgery at Harvard is surgeon. Dr. Cushing was elected an honorary Fellow of the Royal College of Surgeons of England in 1913, and in recognition of what he did for British soldiers during the war, when he worked at various casualty clearing stations in France and acted as consultant in head injuries, he received the C.B.

The next of the exchange lectures with Dutch universities arranged by the University of London will be given on Wednesday next, June 21st, by Dr. A. A. Hijmans van den Bergh, professor of pathology at Utrecht. The subject is "The pathology of haemoglobin." The chair will be taken by Sir Frederick Andrewes, M.D., F.R.S., at 5 p.m. A reception will be held at 4.30 p.m.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons resumed its sittings on June 12th.

The Case of Ronald True.

The action of the Home Secretary in remitting the death sentence upon Ronald True and ordering his committal to Broadmoor Asylum was the subject of questions in the House of Commons on June 13th.

The Home Secretary's Statement.

Mr. Shortt, replying to a question addressed to him by Mr. Stanley Holmes, made a lengthy statement. He said he hoped to show that the course taken by him was in every way essentially what would have been taken, and could only have been taken, by any other Home Secretary, and was in entire accordance with the practice in every case in the past for very many years. He understood that his action had been criticized on two grounds: First, that he should not have instituted the medical inquiry into the mental condition of True; and secondly, having received the report, he need not have acted upon it. It had been suggested that he, in instituting the further inquiry, had in some degree reopened the issue, whereas he should have regarded it as having been closed by the findings of the jury by which the case was tried. It was alleged that he had slighted the verdict of a British jury and the decision of the Court of Criminal Appeal. He maintained that he had done nothing of the kind.

Mr. Shortt then quoted Subsection 4 of Section 2 of the Criminal Lunatics Act of 1884, under which if the Home Secretary had reason to believe that a condemned prisoner was insane it is laid down that he "shall" order an inquiry. (The subsection is printed at p. 965.) At that time he had before him the reports of the two prison doctors who had had the prisoner under close observation for nearly two months. These doctors gave evidence at the trial, as did two other medical men, that the prisoner was certifiably insane. He knew also that no rebutting evidence was called during the trial, for the reason that the prosecution found itself unable to obtain such evidence. This did not mean that the jury were wrong in finding the prisoner guilty. There were, in fact, two issues which were quite distinct. The first was: Was the prisoner at the time he committed the offence insane within the limits of the doctrine of criminal responsibility as laid down by the courts? That was a question on which the jury gave an answer. The further question which arose under the Act was whether the prisoner at the time of the statutory inquiry (being then under sentence of death) was insane within the meaning of the Act so as to be certified and removed to an asylum. That question was left by the statute to the unfettered judgement of two or more medical men; and in instituting such a medical inquiry he was in no way running counter to the views of the judges. On the contrary, the judge who tried the case in the first instance, in reporting that he had passed sentence of death, drew the special attention of the Home Secretary to the medical evidence as affording matter for further consideration, and at the conclusion of the appeal the Lord Chief Justice said that there were certain powers which in proper cases were always exercised by the Home Secretary. In

summing up his information Mr. Shortt said that he thus had (1) the report of the prison doctors saying they considered the prisoner at the time certifiably insane; (2) the request of the learned judge who tried the prisoner that he should carefully consider the evidence as to insanity; and (3) the very plain hint of the Lord Chief Justice. If in these circumstances he had neglected to put the provisions of the statute into operation by directing a medical inquiry, he would have been guilty of a flagrant breach of public duty, and when challenged he would have had no defence.

Mr. Shortt next came to the second point of criticism—that having received a report that the prisoner was insane he was not bound to act upon it. He said that those who took that view were under a complete misapprehension. The principle that an insane man should not go to execution had been enshrined in the law of this country for at least 300 years. He quoted Sir Edward Coke, Sir Matthew Hale, Serjeant Hawkins, Blackstone in his *Commentaries*, a solicitor-general of the time of William III, and Stephen in his *Legal Commentaries*. All these quotations set forth in unequivocal language that an insane man should not be put to death. Mr. Shortt next referred to the eminence of the doctors whom he asked to serve as a committee of inquiry. Two of them were most highly experienced official doctors, who had been

One of these two had been Asylum, the other was a prison commissioner. Both were men who for years had had the complete confidence of all the judges when giving evidence as to sanity or insanity. The third doctor, Sir Maurice Craig, was a very well-known specialist. When these doctors unanimously reported that the prisoner was certifiable by the law of the land, reprieve had to be granted.

Mr. Shortt afterwards dealt with what he described as the cruellest criticism that could possibly be made against him—the suggestion in some quarters that he had been actuated by some influence in the form of aristocratic pressure on behalf of the prisoner. He assured the House that he knew nothing as to who True was or who were his relations. No communication had been made to him except by the learned judge, and no communication had been made to the Home Office until the committee was set up, when the solicitor for the defence presented a petition for reprieve, as generally happened in these cases. Subsequently Dr. Dyer saw a relative in order to take evidence as to the prisoner's antecedents.

Mr. Shortt closed by asking the House to believe him when he said that he was actuated in this case, as in other murder cases, solely by the merits of the case; he was loudly cheered as he sat down.

Mr. Stanley Holmes asked leave to move the adjournment of the House to discuss the question.

The Speaker said he must make it quite clear that no question of adjournment could arise on the advice tendered to His Majesty by the Home Secretary with regard to a reprieve or the contrary. That principle had been the settled practice of many years. He put the question to the House on other grounds. The question could only be as to whether the Home Secretary had acted rightly under the powers which were entrusted to him in this matter.

Only twenty-eight members rose in their places; as the number requisite for leave to move the adjournment is forty, the motion fell to the ground.

Mr. Shortt was again cheered as he left the House.

Ministry of Health Vote.—In the vote for salaries and expenses of the Ministry of Health, Sir Alfred Mond, on June 13th, stated that the estimates of his department showed a reduction of £1,372,000, without any diminution of the outlay on public health services such as the treatment of tuberculosis, maternity, child welfare, and venereal diseases. Referring to the promise of the Rockefeller Institute to give two million dollars (£400,000) to found a school of hygiene in London if the necessary money for maintaining it were provided, he reminded the House that he had promised that if the work could be done for £25,000 a year, that amount should be furnished; in a couple of years this service would be begun. The total amount of grant so far paid out to voluntary hospitals was about £103,000 in London, and about £39,000 in the provinces.

Chemicals for Research Work.—Dr. Raw asked, on June 12th, whether the President of the Board of Trade was aware of the statement of the secretary of the Royal Holloway College, that as a result of the passing of the Safeguarding of Industries Act, one-third to one-half of the time of research workers was spent in preparing compounds which formerly could be bought. Mr. Baldwin said he was aware that such statements were made. Imports were not prohibited. He suggested that research workers should place themselves in direct communication with British makers of fine chemicals; they would welcome any detailed criticism and co-operation in the development of the British industry.

INJURIOUS AGENTS AND GROWTH.

DR. MURK JANSEN'S LECTURE.

ON June 12th a lecture on "Injurious agents and growth" was delivered at the house of the Royal Society of Medicine, under the auspices of the University of London, by Dr. Murk Jansen, O.B.E., lecturer on orthopaedic surgery at the University of Leyden, Holland. The chairman, Professor Elliot Smith, F.R.S., referred to the pioneer work of Dr. Jansen as an orthopaedic surgeon of international reputation, as one of the men who has done most to bring the medical profession in Holland and England into closer touch, and as a sympathetic friend of our soldiers and sailors interned in Holland.

The lecturer showed how his method of determining the causal factors and explaining feebleness of growth is based on the . . . of the same parents—preferably chosen from large families—with regard to the injurious influences to which they have been subjected either before or after birth. Three fundamental principles of feebleness of growth were enunciated:

1. The feebleness of growth is proportional to the intensity of the injurious agent.

2. Feebleness of growth is proportional to the rapidity of the growth of the individual and its parts, so that the main effect of the injurious agent falls upon that part of the body which is growing most rapidly at the time the injury is inflicted.

3. Feebleness of growth is characterized by enhanced sensibility to the injurious agent and enhanced fatigability. Achondroplasia was discussed as an example of congenital feebleness of growth. The shortening of the base of the skull, the tilting upward of the posterior margin of the palate, and the dorso-lumbar kyphosis were regarded as due to increased folding of the flexible sclero-blastomous skeleton between the third and sixth weeks of embryonic life, as a result of the increased hydrostatic pressure produced by an amnion which was lagging in growth. The increased amniotic pressure led not only to positive pressure signs but also to relative anaemia of the foetus by expression of the blood.

As an example of feebleness of growth after birth, the serial members of large families were discussed. In a given family, for example, the eldest child exceeded normal height, and presented the four classical symptoms of muscular weakness—namely, round back, protuberant abdomen, flat feet, moist and blue extremities. This child had a musculature too weak to bear the body weight; in short he had "out-grown his strength." The succeeding two or three children were of average height, displayed muscular weakness, and in addition some degree of knock-knee, so that the stress of the injurious agent fell on the region of most rapid growth—that is, at the growth discs or epiphyses in the neighbourhood of the knee. The remaining children displayed less than the average height and marked muscular and skeletal changes ranging from the so-called rachitic condition to that of pedatrophy or athrepsy.

The tissues which undergo most rapid growth from the newborn to the adult condition are muscle and bone, the muscle increasing from 25 per cent. in the newborn to 43 per cent. in the adult, and the skeleton increasing from 14 per cent. to 18 per cent. The growth in length of the skeleton takes place at the epiphyses and the greatest increase in length takes place at the epiphyses bounding the knee. Accordingly the clinical facts accord with the three principles enunciated, and the stress of the injury falls on the fast-growing cell groups, so that the result is muscular weakness, muscular weakness with knock-knees, rickets involving the ends of the bones, rickets involving the shaft of the bones, and lastly complete athrepsy.

The histological characters of the epiphyses were next considered, and the costo-chondral junction was taken as a type. The histological section displays three zones—namely: (1) a zone of multiplication of cartilage cells; (2) a zone of enlargement and specialized arrangement of cartilage cells; (3) a zone of cell differentiation where cartilage cells become differentiated in accordance with the formation of bone. Cell differentiation is more vulnerable than cell enlargement, and cell enlargement more vulnerable than cell multiplication, so that a given injurious agent will lead first of all to failure of cell differentiation with heaping up of the cartilage cells to form an enlargement; a stronger injurious agent will lead to lack of

differentiation and lack of cell growth; still stronger injurious agents may lead to the third degree—that is, lack of cell division.

The manner in which feebleness of growth was characterized by enhanced sensibility and enhanced fatigability was shown by a series of curves in which functional pressure was plotted on the horizontal axis and growth on the vertical axis. The curves for normal skeletons, for skeletons with slight feebleness of growth, and for skeletons with severe feebleness of growth were discussed in a most suggestive manner.

In conclusion Dr. Jansen indicated that the purpose of this work on feebleness of growth was essentially prophylactic. Sufficient evidence had been adduced to justify the need for the protection of the mother from overwork, poverty, and worry. The results already obtained with regard to the vulnerability of the fast-growing cell groups to injurious agents justified an inquiry into the action of alcohol and tobacco on the father, an inquiry which had already been made in the case of the harmful effect of x rays. A hearty vote of thanks was accorded the lecturer.

MEDICAL TERMS IN THE VERNACULAR AND THE DIALECTS.

III.

SMITTLE AND SMIT.

EVERY doctor in Scotland and the North of Ireland knows that smittle means infectious, but the word is so widespread in English dialects also as to be in use in all the northern counties, as well as in Derbyshire, Lincoln, and Nottingham.

Like so many vernacular medical words, smittle (as verb, noun, and adjective) has several forms: in Yorkshire it sometimes appears as smicklo (verb and noun), but more commonly, as in many other counties, as smit (verb and noun), and as smitting (participle); in some parts of Lancashire it is transformed into smitching, and in some other parts of the North of England the word used is smittling, and in Fife smittal; smittleish or smittlish is fairly widespread. Smittleness is, of course, infection; a smitting sickness is an infectious disease. Smiting and smitten are not, strictly speaking, forms, although in meaning they approximate.

Smittle, according to the *New English Dictionary*, is derived from the verb smit, which means to stain, contaminate, tarnish, mark (as one does sheep), and to infect or affect by contagion. Smit, again, has been formed on the Old English smittian, the weak grade of smitan, to smite; and it is to be noted that smito in obsolete senses meant to pollute, blemish, or smear. In other Teutonic languages there are similar words with like meanings. Thus in Swedish there are smitta, smittkoppor (small-pox), smittsam, and smittsambet (infectiousness); and in Middle Swedish there was the almost identical word smittol (infections). In Norse smittestof means contagious matter. Dr. James Colville¹ connects smittle with the Icelandic smeita, steam from cooking fat. In Dutch there is smet, meaning a blemish or spot; and Dr. Colville² points out that when a Boer in South Africa, speaking the Taal, says "daar teekens is van een besmettelijke ziekte" (there are tokens of an infectious sickness), he is not far from the vernacular smittle. In German, likewise, there is schmitz, a stain, and schmitz, filth. It would be easy to pass more widely into less established etymological relationships, as, for instance, through smito into such meanings as to throw, to strike, to smear, or through smut into smudge and blacken; but this would be to leave the present-day signification of smittle, although it is of some weight that the editors of the *New English Dictionary* think that the sense of throwing is perhaps the original. Dr. Johnson does not give smittle in his dictionary, and Bailey gives only smiting, meaning infections, as in use in Lincolnshire.

Thomas Carlyle, in writing of the words selaric and siare, reflects, "What long-drawn echo of bitter rage and hate lies in that small etymology!" and, in dealing with smittle, we may similarly see underlying the word no little past terror and dread. We go back in thought to the dreary days and the gloomy nights when some plague or pestilence or Black Death was sweeping over these islands, and when our ancestors, escaping from the towns and fleeing even from each other, would whisper the "creepy" word smittle and visualize dimly some horror of a malign force casting death-laden evil things at mankind, baleful and noisome. All was mysterious, weird, and full of awe; often the plague was communicated

from one individual to another—that is, snittle; sometimes it apparently passed by and the "contact" escaped, but one could not tell. It will be said that now much more is known, and that in cocci, bacilli, and spirilla any microscopist can see the causes of snittleness or infectiousness, which were hidden from his ancestors; but there is a danger that even the modern pathologist knows not why or how they actually produce disease, or why they do so at one time to the height of an epidemic, and why at other times they lie quiescent. Snittle is still a "small etymology" which has something of terror for us, when we think of our ignorance of its ultimate nature and mode of working or leaving alone. When a doctor in India meets a swarm of flies which have been resting on a group of lepers and are now winging their way towards him he confesses to at least a feeling of apprehension; influenza gives the nation an annual scare; and pneumonic plague is a horror.

Snittle and smit are met freely in the literature of Scotland and the north of England, and are in every day employment in the tongue of the people. Andrew Winton (1350?–1420?), the Scottish historian, who fortunately wrote his *Chronicle* in the vernacular and not in Latin, used smit in the figurative sense of moral contamination as well as in the literal meaning of a spot or taint or infection. With the meaning of infected, smit was used, as Jamieson pointed out in his *Scottish Dictionary*, in the Acts of James I of Scotland, the disease referred to being leprosy: "that the Bishopis, Officialis, and Denis inquire diligente in their visitation of ilk parochie kirk, gif ony be smittit with lipper." Smit was even admitted to the high rank of a proverb word as in the saying, "ae scabbit sheep will smit a hail birls" (dock). In the sense of pollute, Whyte Paterson uses smit "in the sentence, 'for I ne'er wad lat wrang smit my lips.'" Snittle (in Scotland, at least) has generally been more restricted in its meaning, and has uniformly indicated infections or to infect. Wright, in the *English Dialect Dictionary*, has given many illustrative quotations: "Such was the dread of the smittal disease, that they wouldna let them into the toons wi' the corps"; "thero never was a plague, either on beast or body, mair smittal than that [inderpest]"; "our trouble seemed a smittal one." The last quotation comes, it is interesting to note, from a book written by a medical man, D. M. Moir of Musselburgh, better known as Delta, the popular contributor to *Blackwood's Magazine*. Similar usage obtains in the north of Ireland: "hoo did ye get the maiseis?" "a wus smit at the skael"; "they say the coal's smittal."

In the dialects of Northern England smit and snittle have wider meanings than in Scotland and Ireland. Sometimes they have the signification of infect as in the Lincolnshire question, "are measles smitting?" the Yorkshire phrase, "she's gotten fever, an'll smit tha," and the Westmorland "small-pox are very snittle"; but they have also the sense of similarity, as in the Yorkshire phrase, "she's the smit of her mother"; or that of smutted, as in "smitted clothes are the plague of the housewife on the washing day"; or that of "marked" like sheep. Farther away from the original meaning is that of "likely," as in the Northumberland "it's a smittal spot for a salmon"; and still farther is that of "sure" or "certain as a stock-getter" in the Cumberland expression, "as smittal as t' smoo'-pox," said of a successful male animal kept for breeding purposes. One can, however, trace the connexion in idea.

ACCORDING to a recent census the increase of the population of Paris during the last ten years is confined exclusively to the foreign inhabitants, the number of whom has increased from 158,000 in 1911 to 169,527 in 1921. The female population is largely in excess of the male. The differences between the two sexes is greatest between the ages of 20 and 30.

THE fourteenth Congress of the Italian Psychiatric Society will be held in Rome from October 19th to 21st, when the following subjects will be discussed: (1) Nosography and pathogenesis of the psychonoses, introduced by Professors Modena of Ancona and Morselli of Genoa; (2) pathogenesis of so-called essential epilepsy, introduced by Professors Besta of Milan and Roncoroni of Parma; (3) schizophrasia and pseudo-schizophrenia, introduced by Professors G. Montessano of Rome and Kolijinski of Genoa; (4) pathological anatomy of psychasthenia, introduced by Drs. Arcini of Arezzo and Pilotti of Rome.

England and Wales.

CONGRESS OF OBSTETRICS AT LIVERPOOL.

THE British Congress of Obstetrics and Gynaecology will be held in the Medical Institution, 107, Mount Pleasant, Liverpool, on Friday, June 30th, and Saturday, July 1st. The following bodies will take part: Royal Society of Medicine (Obstetrical and Gynaecological Section), Edinburgh Obstetrical and Gynaecological Society, Glasgow Obstetrical and Gynaecological Society, Midland Obstetrical and Gynaecological Society, Royal Academy of Medicine (Obstetric Section), and the Ulster Medical Society. The proceedings will include a discussion on the results of treatment of eclampsia, and operations at the Liverpool Royal Infirmary. The Congress dinner will be held at the Midland Adelphi Hotel on the evening of June 30th.

LIVERPOOL STANLEY HOSPITAL.

THE annual meeting of the Liverpool Stanley Hospital took place on May 22nd, and, as in the case of the other three general hospitals of the city, the report for the past year showed a deficit. At present the debit balance stood at £8,012; there had been a diminution in expenditure, but unfortunately the cost of maintenance was still much in excess of that incurred in pre-war years. The treasurer remarked that the absence of new subscribers who realized their responsibilities was a notable state at the present. There was a gap left by those good citizens who had supported the hospital in years past, to be filled up by the rising generation, if the voluntary system was to be maintained. The hospital was thoroughly equipped and able to meet the wants of the northern area of the city. The committee had now in hand sufficient money to enable them to provide accommodation for patients of moderate means, and this sum, amounting to £20,548, was to be devoted to the new building for the reception of patients on a contributory basis. It was pointed out that forty years ago the hospital was in sore straits financially, but was speedily relieved through the generosity of Liverpool citizens, and the committee looked forward to a similar effort by the public.

CENTRAL MIDWIVES BOARD.

THE Central Midwives Board for England and Wales met on May 31st, and held a special penal meeting, followed by the ordinary monthly meeting. Sir Francis Champneys presided. Seven midwives were cited to appear, and the names of three were removed from the roll. The Board agreed to consider carefully an inquiry from the town clerk of Kensington as to whether, in view of the prevalence of ophthalmia neonatorum, a direction to midwives might be issued from the Board as to the routine application of a suitable silver preparation to the eyes of all newly born infants. The Board decided to take into consideration at its next revision of rules the following resolution received from the inspectors of midwives and teachers of practical midwifery: (1) That the period of training of pupil midwives be lengthened; (2) that midwives approved by the Central Midwives Board to teach practical midwifery possess definite qualifications besides that of holding the Central Midwives Board certificate.

Scotland.

PROFESSOR CALMETTE, AT EDINBURGH.

AN address was delivered on June 7th before the members of the Medico-Chirurgical Society of Edinburgh, with Professor Sir Robert Philip in the chair, by Professor A. Calmette, of the Institut Pasteur of Paris, on "The protection of mankind against tuberculosis." He said that after he had demonstrated the specific character of the tuberculous virus and its inoculability to different animal species, Villemin, finding it difficult to transmit tuberculosis to the dog, the cat, and the sheep, was the first to raise the question of whether any animals were immune to this disease. Later, after the discovery of the tubercle bacillus by Robert Koch, it was found that almost all the mammalia could be artificially infected, but that a small number of species could contract tuberculosis spontaneously, and that some others were so highly resistant as to be immune even to artificial

inoculation. The problem might be put as follows: How to render the leucocytes and the endothelial cells of the vessels—which enclose the tubercle bacilli but are unable to digest them—how to make these cells non-sensitive to the poisons which these bacilli contain and secrete (endo- and exo-toxins), so that the organism may tolerate the presence of a number of inoffensive foreign bodies, such as particles of silica, carbon, or metallic fragments, even of considerable size. It seemed that for man, as for animals prone to tuberculosis, such as the bovines, one early and slight inoculation was desirable, provided that it was not followed by further repeated massive infections. Such slight inoculation conferred on the organism a resistance which, while not a true immunity, protected it in case of subsequent grave reinfections from a rapidly fatal form of the disease. It might be affirmed that every subject infected in childhood by a very feeble dose of bacilli was rendered less likely to contract acute miliary tuberculosis. It was very difficult to prosecute investigation in antituberculous vaccination in laboratories and in countries where bacillary infection was so widespread that a given animal could not certainly be protected from accidental contagion. That was why he had proposed the creation of a centre of research in a position as isolated as possible, preferably on the West Coast of Africa, in the great belts of forests inhabited by large anthropoid apes, especially the chimpanzee.

PRESENTATION TO SIR JOHN MACPHERSON.

A presentation was made on June 6th by professional and other friends to Sir John Macpherson, M.D., in recognition of his long and eminent services devoted to the interests of the insane. He recently retired from the post of H.M. Commissioner of the General Board of Control, and is about to proceed to Sydney as professor of psychiatry. The ceremony took place in the hall of the Royal College of Physicians of Edinburgh, with Professor Sir Robert Philip, President of the College, in the chair, and Lord Polwarth, in handing a piece of plate and a cheque to Sir John Macpherson and a diamond brooch to Lady Macpherson, congratulated them on the honour which had so rightly been awarded by His Majesty. Sir John Macpherson had played an important part in lunacy administration in Scotland, and his friends wished him a very happy time in Sydney. In returning thanks Sir John Macpherson said that his own connexion with Scottish lunacy began in 1883, when he became an assistant medical officer in Stirling District Asylum, and shortly afterwards he went to Morningside under the then greatest living authority, Sir Thomas Clouston, whose memory as a master and teacher he revered. He could testify, as his predecessors had done, to the cordial relations which existed in Scotland between the medical and lay authorities concerned with the care of the insane. By the hospitalization of asylums, skilled nursing, open-air treatment, open-air work, and as great an extension of liberty as was consistent with actual safety, suffering had been relieved and life under abnormal conditions made more endurable.

MONCRIEFF-ARNOTT CHAIR AT EDINBURGH.

The appointment is announced of Dr. Edwin Bramwell, F.R.C.P. Lond. and Edin., F.R.S. Edin., to the Moncrieff-Arnott chair of clinical medicine at the University of Edinburgh, in succession to the late Professor Francis D. Boyd. Dr. Edwin Bramwell is a son of Dr. Byrom Bramwell, the distinguished Edinburgh physician, and has made his reputation chiefly in the study of diseases of the nervous system. He is physician to the Edinburgh Royal Infirmary and lecturer on clinical medicine and neurology in the university.

THE GLASGOW EYE INFIRMARY.

The writer of the article on "The medical institutions of Glasgow," published in our issue of June 3rd, desires to correct a wrong impression which is conveyed in the note on the Glasgow Eye Infirmary. That infirmary did not really begin in its present site at Berkeley Street, but had its origin on a very small scale in a street now no longer existent, near North Albion Street, which again is a street close to High Street, where the old university buildings stood. This was in 1824, and in 1835 the infirmary was removed to College Street; in 1852 the directors purchased a house in Charlotte Street, formerly the residence of David Dale, a well-known Glasgow merchant. The hospital in Berkeley Street was not opened till 1874.

Ireland.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At a meeting of the Royal College of Surgeons in Ireland on June 8th for the election of President, Secretary, and Council for the ensuing year, the following were elected:—President: Sir William I. de Courey Wheeler. Vice-President: R. Charles B. Mannsell. Secretary: Sir Lambert H. Ormsby. Council: John B. Story, Sir Thomas Myles, Sir Arthur Chance, Sir Lambert H. Ormsby, George M. P. Murray, R. Bolton McCausland, Sir F. Conway Dwyer, Sir Robert H. Woods, Richard Lane-Joynt, Sir William Taylor, Thomas E. Gordon, Alexander J. Blayney, Trevor N. Smith, Sir C. Arthur K. Ball, Major-General R. H. S. Sawyer, Louis A. Byrne, Andrew Fullerton, Seton Pringle, and Edward Sheridan.

Sir William I. de Courey Wheeler is a son of the late Surgeon Wheeler of Merrior Square, Dublin, and Robertstown, co. Kildare, a former President of the College. He has been a member of the Council of the College for the past seventeen years, and acted as President during the illness of the late Mr. E. H. Taylor. He was created a knight in 1919 for his services during the war. He has been visiting surgeon to Mercer's Hospital for many years, and represents Ireland on the editorial staff of the *Medical Annual* and of the American journal, *Surgery, Gynecology, and Obstetrics*, and is also a member of the editorial staff of the *British Journal of Surgery*, under the chairmanship of Sir Berkeley Moynihan. He is acting as one of the secretaries in connexion with the International Congress of Surgery to be held in London in 1923.

Sir William Wheeler is the author of a textbook on operative surgery, which has reached a fourth edition. He graduated in Trinity College with a moderatorship. For several years he was a demonstrator of anatomy in the School of Physic, and acted for a short time as assistant to the late Professor D. J. Cunningham. He is consulting surgeon to the Blackrock Orthopaedic Hospital, for the foundation of which he is largely responsible, and he presides over the City of Dublin Nursing Institution, which has played a conspicuous part in advancing the interests of Irish nurses. He married the Hon. Elsie, eldest daughter of Lord Shaw of Dunfermline, who is at present in Ireland acting as Chairman of the Reparations Commission.

ULSTER MEDICAL SOCIETY.

The annual general meeting was held in the Medical Institute, Belfast, on May 25th; the President, Dr. Robert Hall, occupied the chair. The annual report of council, the honorary librarian's report, and the honorary treasurer's statement of accounts, were submitted and approved of. The deficit shown in last year's accounts of £150 had been reduced to £102, although the society's work had in no way fallen off. Much regret was expressed at the necessity of having a voluntary extra-subscription fund and of asking contributors to the society's proceedings to pay in part the expenses of publication in the *Transactions*, and hearty thanks were given to those who had thus aided. It was decided to carry out the pressing repairs to the building which had been required by the trustees. The following officers were elected for the ensuing session 1922-23: President, R. J. Johnstone, M.B., F.R.C.S. Eng., M.P.; Vice-Presidents, Dr. J. T. Créery (Coleraine) and Dr. V. G. L. Fielden (Belfast); honorary treasurer, Dr. S. I. Turkington; honorary librarian, Dr. W. L. Storey; honorary secretary, Dr. Robert Marshall, F.R.C.P.I.; honorary editing secretary, Mr. G. R. B. Purce, M.Ch., F.R.C.S. Edin. Council: Dr. H. L. McKisack, F.R.C.P., Dr. Jas. Colville, Dr. Maitland Beath, Dr. W. W. D. Thomson, Dr. Foster Coates, Dr. Boyd Campbell.

THE Royal Northern Hospital has received £500 from the executors of the late Miss Amy Hill (who was associated with the institution for forty-four years), £1,050 to endow a "Frederick Brazil" bed from the executors of the late Mr. Frederick Brazil, and £1,000 from the executors of the late Mr. Joseph Grisby Spence.

THE late Mr. James Templeton of Glasgow and Dunblane has by his will bequeathed £2,500 each to the Western Infirmary, Glasgow, the Victoria Infirmary, Glasgow, the Royal Hospital for Sick Children, Glasgow, and the Western Infirmary, Glasgow, and £1,000 to the Medical Missionary Society, Glasgow.

Correspondence.

THE INTERSTITIAL GLAND AND SEX PROBLEMS.

SIR,—Dr. Leonard Williams's paper on the interstitial gland, published in the *JOURNAL* of May 27th, was most interesting. If his suppositions are correct, and it is possible for a male child to grow up morphologically male but "interstitially" largely female, then, as he suggests, homosexuality in such an individual ceases to be a felony, and must be regarded as normal *per se*. But if this latter suggestion comes to be accepted, we may look for some striking defences in cases of unnatural crime.

Referring to sex causation, while one is keenly alive to the fact that most of our knowledge of this fascinating subject is founded on theory, some of Dr. Williams's statements, and at least one of the conclusions he arrives at, are scarcely in accordance with the results obtained by recent research. For instance, he says:

For several weeks the embryo is neuter, and we are to suppose that the male element and the female contained therein are striving for mastery the one over the other.

The rather sweeping statement that the "embryo is neuter" must strike somewhat strangely on the ears of most embryologists. Rumley Dawson stated in his paper in the *Obstetrical Society's Transactions*,¹ that the human ova have their sex already definitely fixed prior even to their debiscence. In the posthumous edition of his book² he wrote:

The male ova arise from the right ovary and the female from the left ovary, so that the female infant is born with her primitive ova already either male or female, and thus the causation of sex comes to be dependent on the woman alone.

Whitridge Williams (Baltimore)³ admits that until very recently we were almost absolutely ignorant concerning the causation of sex, and that it was generally believed that it did not become established until some time after fertilization. He points out, however, that recent investigations clearly show that this is not the case, but that the sex is determined in the germ cells either primarily or immediately after their union, so that it has become immutable by the time segmentation of the ovum begins. As the youngest human ovum yet recorded—the Teacher-Bryce ovum—is only about 13 days old and exhibits the trophoblast stage, it follows that "neutrality of sex," if it exists at all, cannot be a matter of weeks.

Then again, in regard to the interstitial gland in the female, if, by this term, one is to assume those hypertrophied theca cells which develop around the periphery of follicles undergoing atresia, one can dismiss it as being of but secondary importance as regards an internal secretion, as according to Williams of Baltimore,⁴ clinical observation bears out Fränkel's statement that the internal secretion is elaborated in the corpus luteum. If we are to accept Rumley Dawson's sex theory at all—and, so far as I have been able to ascertain, no later investigations have actually disproved it—then, instead of administering male interstitial gland, as Dr. Williams suggests, in cases of deficient "maleness," one would require to administer corpus luteum extracted from the right or male ovary, and from the left or female ovary in cases of deficiency in "femaleness."—I am, etc.,

R. DOUGLAS HOWAT, L.R.C.P. and S.Edin.

Denholm, Hawick, May 30th.

SIR,—In the otherwise illuminating and suggestive paper by Dr. Leonard Williams published in the *BRITISH MEDICAL JOURNAL* of May 27th there is an expression of opinion with which medical men as a whole will, I am confident, disagree, and a statement to which, I am equally confident, they will take the severest exception.

The author quite rightly maintains that the attitude adopted by a civilized community towards homosexuality is of social importance. Now the general attitude of the British community towards such practices is one of utter detestation. Dr. Williams proceeds to admonish society on this—to him—incorrect attitude, and to warn it that, if it is to merit the qualification "civilized," it must not place too many legal, moral, and conventional obstacles in the path of those who are inclined in the direction of this practice. He says:

I am entirely of the opinion . . . that the present law on the subject requires revision. Regarded in the light of pure physiology, it is no more reasonable to punish a man for being homosexual than it would be to punish him for having red hair. Both of these things are burdens cast upon him by forces over which he has no sort of control, nor can he alter or modify them by any effort of the will.

As strict matter of fact a man is not punished for being a homosexual. Indeed, if we are to believe some of the extravagancies of Freud and Jung, to say nothing of the unutterable twaddle of certain of their disciples—the neo-psycho-analysts—we are all in the same position in relation to homosexuality, and punishment is therefore out of consideration. Legal punishment is only inflicted on an individual who is proved to have committed an act of homosexuality, a totally different thing, since in the one case we are dealing with a state or condition, in the other with an act, or rather acts. But Dr. Williams would have the law on the subject relaxed, and the community "educated" up to a lofty indifference to a disgusting and opprobrious vice—a vice that is after all as old as the ancient Syrian town on the northern slopes of the Dead Sea from which it takes its name.

While not for a moment admitting the validity of Dr. Williams's statement as quoted above, I would ask the question, Why should society enact its rules solely "in the light of pure physiology"? It could equally be pleaded of the man who, on a hot perspiring day in August, strolled down the Strand in his birthday suit, or who obeyed the calls of nature in the middle of the public thoroughfare, that, "regarded in the light of pure physiology," it would be unreasonable to restrain him. And whither does such argument lead? To be consistent, Dr. Williams will have to admit that individuals addicted to lesbianism, tribadism, sapphism, masochism, and all other "beastly isms" of the sexual perverser no more merit punishment than do the possessors of red hair! Nor should he exclude thieves and cut-throats. Fortunately, however, society has not so evolved and framed its laws of conduct. While making all due provision for physiological and, it should be added, pathological factors, it recognizes these only in conjunction with many other equally important factors, and it insists that such eccentrics should be clapped either into prison or madhouse. It does so with three objects: to cure the individual of his antisocial proclivities, to deter others from like conduct, and to rid itself of that which is a source of annoyance and disgust.

Dr. Williams reminds us that it is not so very long since people were tortured for being insane. He might, with equal disregard for relevancy, have called attention to the fact that in those good old times epileptics were deified.

Although a determinist I disagree entirely with the statement that homosexual acts, like red hair, are "burdens cast upon" the individual "by forces over which he has no sort of control, nor can he alter or modify them by any effort of the will." Each one of us is undoubtedly within the clutch of circumstance, and our acts are but links in an infinite and inexorable cause-effect chain. Nevertheless, education, law, environment, etc., all have their place in that chain, and consequently our acts are, in their relation to other parts of the chain, very materially modifiable. Acts are determined by the strongest desire at the moment of action, and a good society will see to it that education, environment, reward, and punishment, subordinate the primal urge to evil to a stronger desire to refrain from evil.

It may be stated with tolerable certainty that the overwhelming majority of homosexual acts are perpetrated by individuals who have acquired the practice—that is to say, in whom the tendency towards the vice was not inborn or germinal. Such cases resulted from faulty nurture, not faulty nature, and therefore were preventable. It may be an ugly thing to say in cold blood, but none the less it is true, that in the present state of society, if the law in relation to homosexuality were to be relaxed; the vice would increase with a great promptitude and certitude as would boodgicism in a great city if all the physical forces of law and order were to be removed.

Dr. Williams thinks it "high time that the members of our profession expressed strong and clear views on this question." I cordially agree and sincerely hope that a vigorous response to his suggestion will be forthcoming. A lenient attitude towards perpetrators of homosexual acts constitutes a grave social danger.—I am, etc.,

C. MARSH BEADNELL,
Surgeon Rear-Admiral, R.N.

FATAL BOTULISM.

SIR,—In the interesting annotation (June 3rd, p. 893) attention is drawn to the considerable number of outbreaks, reported as "botulism," that have been observed during the last few years in the United States.

It is perhaps deserving of emphasis that in respect of only a very small minority of those outbreaks of associated cases of acute nervous disease has there been any show of attempt to demonstrate, by bacteriological or serological methods, the connexion of the cases with *B. botulinus*. And I do not know that in connexion with any one such attempt has the demonstration been so conducted as to satisfy any competent bacteriologist of its sufficiency. Moreover, there do not appear to have been lately conducted any fresh experiments tending to show that the bacillus called *botulinus* is really responsible for outbreaks of the kind reported as due to "botulism." Again, no definite clinical criterion appears to be established that distinguishes all cases called "botulism" from all others called "encephalitis lethargica," though the former name is reserved for cases occurring in association—usually commensal—and the latter for cases that are apparently dissociated from others in their origins. This, however, is a matter of epidemiology and not of clinical importance. But as the Dorby outbreak of August, 1919, clearly shows (Annual Report of the C.M.O., 1919-20, Ministry of Health, pp. 357 et seq.), commensal association is quite compatible with the diagnosis of encephalitis lethargica.

There are many interesting points that call for discussion, but the object of this letter is to point out the need for a revision, at the hands of critical pathologists and bacteriologists, of the statements made and copied from one book to another concerning botulism during recent years. I need hardly insist that Dickson's demonstration (Monograph No. 8, Rockefeller Institute, 1918) of the fact that the bacillus called *botulinus* will grow on canned tomatoes and beans does not prove that, in a country where canned fruits and vegetables are everywhere consumed, certain types of illness are due to the toxic products of this organism. Nor does Marinresco's investigation of the brains of animals dying or killed after inoculation with this organism or its products help us with regard to the pathology of human cases called "botulism," but of no proven association with the bacillus. In fact, the subject is as obscure as when Grisolles wrote, eighty years or more ago, that we did not then possess any satisfactory description of the effects characteristic of this type of poisoning. All the descriptions, he said, are incomplete and give us only a very slight idea of the physiognomy of the disease and of the nature of the changes produced by it.

One epidemiological fallacy has dogged the history of botulism ever since Kerner first described it one hundred years ago—the fallacy that commensality in relation to an acute outbreak of disease necessarily implies food poisoning. But when, during the Christmas holidays, measles breaks out amongst the participants in a children's party, we do not implicate cakes and jellies.—I am, etc.,

London, W., June 3rd.

F. G. CROOKSHANK.

A PULMONARY SIGN IN ACUTE INFECTIONS OF THE BILIARY TRACT.

SIR,—Mr. Wilkie, in the BRITISH MEDICAL JOURNAL of June 10th (p. 908), draws timely attention to the relationship of physical signs at the base of the right lung to acute lesions of the upper abdomen. He points out our familiarity with the cases which have referred pain in the abdomen from a lesion above the diaphragm, but warns us that the presence of crepitations and other physical signs at the base of the right lung may be in favour of, and not against, an abdominal diagnosis.

The wonder is that pulmonary signs are not more regularly present in patients with an "acute upper abdomen." It is a common experience after operations in "cold" cases, such as gastro-enterostomy, cholecystectomy, etc., to be told by the house-surgeon that the case is "a bit chesty." For the first few days there may be profuse expectoration of the bronchopneumonic type. In the great majority of these cases, the chest symptoms disappear in a few days after an aperient and the first successful evacuation of the bowels—in other words, when the tension in the abdomen is relieved. The condition is vaguely spoken of as either bronchitis and the onus is placed on the shoulders of the anaesthetist. Criticism is silent when a local anaesthetic is employed, and rather complicated explanations are forthcoming when the operator is accustomed to employ anaesthesia administered per rectum.

The fact is that these cases are often due to oedema of the lung, the result of impaired movement of the diaphragm, reflexly as is suggested by Mr. Wilkie, "from irritation of the sensory fibres of the phrenic nerve," or more likely from the mechanical difficulty of diaphragmatic excursions against rigid recti muscles combined with the general effort of the patient to prevent movement in the recently wounded area.

When transient oedema of the lungs occurs so often after high laparotomies in chronic cases, its presence in cases of the acute upper abdomen before operation is not surprising. The causal factors are the same whether mechanical (as I have been in the habit of teaching), reflex, or infective. In 1916 Murphy drew attention to the high mortality from oedema of the lung after closure of large umbilical hernia due to "a deficiency in the action of the diaphragm muscle (the piston of respiration) in breathing."

My only doubt, after reading Mr. Wilkie's instructive paper, is in regard to the limitation of these pulmonary signs to cases with infections of the biliary tract.—I am, etc.,

Dublin, June 12th.

W. DE C. WHEELER.

THE OUTLOOK IN TROPICAL HYGIENE.

SIR,—In your issue of May 20th Colonel A. Balfour, C.B., makes the following statement:

"There was a great need of establishing a special course of instruction in this country for sanitary inspectors destined for the colonies. So far as I am aware, no diploma in sanitary science as applied to the tropics yet exists for sanitary inspectors. All that has been done in this direction is represented by the certificate granted by the Royal Sanitary Institute to sanitary inspectors who have qualified in the examination on tropical sanitation which has been recently instituted." [Italics not in original.]

I concluded therefrom that he was not aware of conditions which had existed for nearly a generation in the Madras Presidency, and more recently in other parts of India; and that he contemplated the provision of a particular course of instruction in tropical hygiene under the Royal Sanitary Institute, in support of its recently evolved certificate. In my letter on the subject (BRITISH MEDICAL JOURNAL, June 10th, p. 935), guarded by the conditional phrase "if that be so," I suggested that modification of the inappropriate method pursued by the Royal Sanitary Institute in bestowing its seal upon certificates of men educated [and examined] locally in the tropics, was a very desirable first step in the matter.

Colonel Balfour has now favoured me with a copy of his paper (not yet published by the Royal Sanitary Institute); in which it is shown that he does not look to the Royal Sanitary Institute for the course of instruction he desires, but to the future Imperial Institute of Hygiene. He regards the Royal Sanitary Institute in this connexion merely as an examining body.

A scheme erroneously described at its initiation is apt to be inhibited in development by doubts incident to incorrect information at disposal of otherwise willing supporters. Hence, as I believe all sanitary workers in the tropics would wish success for Colonel Balfour's scheme in its broad aspects, I submit this amendment of my letter above referred to.—I am, etc.,

London, N.W., June 12th.

W. G. KING, Colonel I.M.S. (ret.).

EXPECTANT TREATMENT OF MEASLES AND INFLUENZA.

SIR,—As no one else has commented on the subject, may I add my voice to those of Major Reginald F. E. Austin (June 3rd, p. 901) and Dr. Thos. Carruthers (May 13th, p. 786); for I believe their contention to be worthy of every support.

I, too, for many years have been preaching the starvation and cold-water treatment of measles and other acute febrile conditions, and am satisfied as to the results. A few days' starvation from food does no harm, and drinks of water do every good.

There is a remarkable dread of cold water among the public. When told to give a feverish child drinks of water the mother almost invariably asks incredulously, "What? Cold water, doctor?" and is sometimes with difficulty persuaded. But I venture to say that warm milk, to a hot, feverish, thirsty child, is a revolting drink to offer.

I shall never forget a case here during an epidemic of what was popularly called "black measles," where three out of five children in one cottage died within a week. Three of them were in bed in one room, and on my visit one day as medical officer of health I was told with dismay that one of them, aged about 2 and just able to walk, had got up in his

delirium, staggered across the room to the washstand, and had wellnigh emptied the water-bottle. I at once said, "Well, it has probably saved his life," as indeed proved to be the case. He was asleep and already perspiring freely when I saw him. Thin barley water, made as tea is made, simply by pouring boiling water over a good handful of pearl barley and infusing till cold, is about the best of the drinks. It is hardly distinguishable from plain water when poured off, but contains the albumin and salts of the barley without the starch. It can be flavoured with thin lemon peel if liked. A large teapot or jugful of this, if put down overnight, is ready for the day's use each morning.—I am, etc.,

Bromsgrove, Worcs., June 8th.

H. CAMERON KIDD.

ENGLAND AND VENEREAL DISEASE.

SIR,—Your review of my little book *Safe Marriage*, in the BRITISH MEDICAL JOURNAL of June 10th, is more than fair; it is very generous. But when you say, "Miss Ettie Rout is rather contemptuous of the England of to-day, and more than doubtful of England's future," you rather misunderstand what I wrote. I certainly believe that on the average the Anzacs are finer than the English in many ways, but that is only natural. Australasia was founded by highly selected British stock in the first instance—discoverers, explorers, sailors, soldiers, pioneers, and adventurers, men such as those who in our times make up the polar expeditionary parties. Second followed men of high character, noble political ideals, and great national vision, their inspiration to found a Greater Britain beyond the seas. Third, we had men and women of high education, great integrity, and sustained courage, many of them connected with different Church settlement schemes; they went out in sailing ships which took months to arrive, and they were indeed fortunate if they could get a reply to a letter within twelve months. Fourth, in Australia we had the cowboys, many of whom were not criminals at all, merely rebels against absurd social conventions and mischievous laws. We got the rebels—you kept the slaves! Fifth, with the discovery of gold came the rush of miners and adventurers of all sorts. That was the beginning of the Anzacs. But there were always and still are far more men than women in Australasia; therefore sexual selection operated favourably in this way: that women were able to exercise a fairly wide choice as to the kind of man they wished to make the father of their children. In England, with its two million surplus women, women have not the same choice. The environment of the Anzacs is also much better on the average than the masses of the people are able to secure in England. We are better fed, better clad, better housed; we have a better climate, more open air life, and we are geographically isolated from the diseased countries of the Old World.

All this is not to say that England has no men equal to the Anzacs. Of course she has! In the learned professions particularly she has many whom we gladly admit to be our superiors, and from whom we gladly learn. Generally speaking, you have more of the graces and virtues of life than we have, and we have more of the crudities and vices. We unite in feeling that the venereal problem constitutes the gravest affront to the pride and state of our empire. But our method of tackling it is—to face the truth; yours is—to deny the facts. Therefore I am optimistic so far as the Anzacs are concerned; pessimistic so far as the English are concerned. The main grounds for pessimism seem to me these:

1. During the war some millions of English men and women became infected with venereal disease, and many of them are still unweaned.

2. From 1919 to 1922 large numbers of Englishmen have been abroad as soldiers in venereally dangerous areas, inadequately protected by disinfective measures, and within that period the number of fresh infections is wellnigh equal to the number of soldiers abroad!

3. During the same period some millions of men and women have been wholly or partially unemployed continuously, forming an idle or floating population, often quite unstable and more or less nomadic, and gradually becoming demoralized.

4. The surplus women have now grown to two millions, and by pressure of their numbers and lack of occupation they tend to lower the prestige of the over-feminine the nation of girls acquired loose or unwilling to

5. London is and highway of the world, and residents a liberty to take any liberty they like with the sexual health of each other.

6. Every effort to induce the people to be clean sexually and to limit the number of their offspring is bitterly opposed; thus the

national stock becomes progressively degraded by the fertility of the unfit who stay at home and the emigration of the fit who go abroad. And every day adds another thousand persons to the swarming population of England!

—I am, etc.,

"ALASTRIM" OR "PARASMALLPOX."

SIR,—There are one or two points in Dr. Jervis's letter in the JOURNAL of May 27th requiring a reply from me.

Firstly, he suggests that, in my letter appearing in your issue of May 13th, after having stated in the second paragraph that *alastrim* is a separate entity, I contradict myself by pointing this in the last paragraph. How Dr. Jervis can possibly read such a meaning into the last paragraph of the letter I am at a loss to understand. His interpretation of the passage is so interesting that, with your permission, I will repeat the paragraph, which says:

"If '*alastrim*' (synonyms: *amaas*, milk-pox, *Kassir* pox, etc.) is a disease separate and distinct from small-pox, it should have a distinctive name. If '*alastrim*' or '*amaas*' are unsuitable names why not call it '*parasmallpox*'? No useful purpose can be served by pretending that it is small-pox." It might be suggested that to call it small-pox would induce people in the areas where the disease is epidemic to submit to vaccination. That subterfuge might, however, defeat its own object—for the native vaccinators would naturally retort, 'If small-pox has lost its power to kill and disfigure its victims, why trouble getting vaccinated against it?'

The second point in Dr. Jervis's letter requiring attention is his reference to the confusion of issues. He says:

"This is not a time for confusing issues; rather is it a time for clear thought and direct action, because knocking at the nation's door at this very moment is what may prove to be one of the most serious epidemics of small-pox which has ever assailed the population of these isles."

The issue raised in Dr. Jervis's first letter, published on April 29th, was one of nomenclature. He appealed earnestly for the utter banishment of the silly word "*alastrim*." I suggested the word "*parasmallpox*," which naturally conveys to any medical mind the meaning "an acute specific infectious disease resembling small-pox." If "*alastrim*" is silly, "*parasmallpox*" is sensible. Some name is required for a disease, which every person who has had opportunities of studying it must admit is not classical small-pox, in order to facilitate discussion. Names or words are our only means of expressing ourselves.

He now appeals, dramatically, not to say picturesquely, for "clear thought" and "direct action." Can Dr. Jervis say what issue has been or is being confused and by whom?—I am, etc.,

R. P. GARROW,
Medical Officer of Health.

Cherterfield, June 7th.

BILHARZIA DISEASE IN SOUTH AFRICA.

SIR,—The presence in Natal of schoolboys who have contracted disease through bathing in the Durban suburbs, and show in their urine the ova of *Schistosomum haematobium*, *S. mansoni*, and ova resembling those of *S. bovis*, emphasizes the need to differentiate the various schistosomes which in their cercarial stage infest the fresh-water snails in South Africa.

One can produce at will the cercariae of *S. haematobium* in *Physopsis africana* which has been bred free from other sources of possible infection, and efforts are being made to secure the cercariae of the rarer schistosomes, whilst other efforts are being made to secure their adult forms.

Bilharzia disease has long been known to exist in the Cape Province, and at one time was very common at Kingwilliamstown and Uitenhage. As the disease also occurs amongst the schoolboys who bathe in Baaken's Spruit at Port Elizabeth; I visited this river in October last and found numerous examples of *Physopsis africana* attached to the rocks, water-lily leaves, and water weeds. Previous collections of this snail from Port Elizabeth failed to show schistosome infestation, but on this occasion it was found to be heavily infested with schistosomes resembling those of *Schistosomum haematobium* and diagnosed by Dr. E. C. Faust as such.

I understand that this is the first occasion that the cercaria of *Schistosomum haematobium* has been identified and the intermediary host responsible determined with certainty in the Cape Province.—I am, etc.,

F. G. CAWSTON, M.D. Cantab.,

Durban, Natal, May 8th.

First Streetfield Research School.

THE CASE OF MR. F. W. AXHAM.

SIR,—In your issue of June 10th Dr. C. O. Hawthorne opens a delicate question which perhaps should be best left alone. It is hardly credible that the honour recently conferred on Mr. H. A. Barker is due—even in part—to the efforts of leading members of the medical profession. If so, it would be interesting to know who they are.

The cases of Sir H. A. Barker and Mr. F. W. Axham are on two different planes. According to the announcement of the knighthood to Mr. H. A. Barker in the *Daily Mail* it was stated that "when quite a child he showed great ability for manipulative surgery." This, if true, indicates that Sir Herbert's ability is congenital, innate, or instinctive in origin—at least, I have never heard of a school where the children were taught manipulative surgery.

In the case of Mr. F. W. Axham his skill in anaesthetics was due to the training he received under the educational supervision of the General Medical Council, and this skill had to be practised in accordance with the restrictions and traditions maintained by that body. If these restrictions and traditions are broken, as they were by Mr. F. W. Axham, the General Medical Council had no option but to act as they did. To reconsider that decision on the ground of the knighthood to Mr. H. A. Barker would be illogical, but there is no reason why the anaesthetist should not be honoured by a decoration lesser than that conferred on the operator.—I am, etc.,

Warrington, June 11th.

J. S. MANSON.

SIR,—Dr. C. O. Hawthorne's letter is surprising. He seems to argue that because the Government or the people, with the connivance of some medical men, has decided to confer the honour of knighthood on an unqualified practitioner, therefore the General Medical Council and the profession at large should regard the practitioner as duly qualified, not only henceforth but retrospectively too.

It is rather disingenuous of Dr. Hawthorne to use the terms "by medical efforts" and "by a medical verdict," as though each equally represented the official action or even the judgement and desire of the medical profession. He makes "no pretence to estimate the value of the work," but in the next sentence implies quite definitely that "restriction" of the worker's "activities" would have been a misfortune in his opinion.

"It is not a question of 'one being exalted and the other condemned' by the same people or body, as he implies, and there is no opening to obvious reproach so far as the profession at large is concerned.—I am, etc.,

Swinton, Manchester, June 12th.

J. PRICE WILLIAMS.

FIRST REPORT OF THE MINERS' NYSTAGMUS COMMITTEE.

SIR,—In your issue of June 10th (p. 932) I should have pointed out that the curious example of the committee's reasoning was a quotation immediately prefaced by the words "An illustration given by Trotter (66, p. 24) will explain the great importance of this reflecting power."

It is clear, then, that the committee give their sanction to the quoted passage.—I am, etc.,

Newcastle-upon-Tyne, June 11th.

ARCHD. STANLEY PERCIVAL.

MACHINE FOR CRUSHING GERMS.

SIR,—In the *British Medical Journal* of June 3rd, 1922 (p. 902), Professor Tanner Hewlett states that we are apparently unaware that several machines have been devised for disintegrating bacterial cells.

We would like to point out that we are well aware of the existence of these machines, since we actually possess in our laboratory the ball-mill devised by Mr. J. E. Barnard. We found this machine so unsatisfactory that we discarded it as useless, and its motor is now used for driving other apparatus. One of its many faults is that the grinding-cup is made of phosphor bronze, while the balls are made of steel. The result is that the ground germ material becomes quite black, due to the admixture of bronze dust. These machines are only capable of grinding germs in a more or less dried or frozen condition, and there is no doubt that an apparatus which will smash germs in a clean watery suspension is much to be desired.

The new machine which we possess is capable of cutting

up yeast cells, and we feel that with further improvements the actual bursting of bacilli will be accomplished.—We are, etc.,

DAVID AND ROBERT THOMSON.

London, W.C.2, June 8th.

DETOXICATED VACCINES.

SIR,—I remove the toxins from my vaccines before sterilizing them because I can see no point in retaining broken inert products in a vaccine when it is possible to remove them.

I am not concerned to deny that fractions of an organism may produce antibodies to themselves when injected into an animal, but I contend that such results do not of themselves prove that the animal treated is thereby immune against attack by the whole organism.

I have never said that heat alone is sufficient to detoxicate a vaccine. I rely upon washing and the action of nascent oxygen. The autoclave is used to obtain rapid and efficient sterilization, and I showed conclusively in my paper that after the washing and the oxygen had done their work heat did not affect the vaccine either in its toxicity or its curative power. I published a large number of cases in support of that statement. So far from the autoclaved vaccine being inferior to the unheated vaccine, it actually showed slightly better results. Dr. Thomson may believe that a temperature of 120° C. destroys the specific antigenic power of any protein, but it would appear that his own quotation of Vaughan's work in the previous paragraph of his letter entitles one to be somewhat doubtful of the precise value of his belief. The fact that my results with an autoclaved vaccine are flatly opposed to the theory on the subject is one of those regrettable instances in which proved clinical facts happen to be at variance with what a theory states they ought to be.

I am aware that we do not test for syphilitic antibodies in the Wassermann reaction. I am obliged for the advice tendered, and, it is almost unnecessary to add, will treat it appropriately. Meanwhile I still await an explanation of how a germ can remain "unaltered" after being washed, treated with nascent oxygen for twenty-four hours, and finally autoclaved.—I am, etc.,

Manchester, June 12th.

C. E. JENKINS.

The Services.

AUXILIARY R.A.M.C. FUNDS.

THE Auxiliary Royal Army Medical Corps Funds are divided into two branches: (a) Officers' Benevolent Branch, and (b) Relief Branch. Up to the end of 1921 the Benevolent Branch has assisted 42 widows and 102 orphans of officers in the Auxiliary R.A.M.C.; the total amount awarded was £5,788. The Relief Branch has assisted 116 widows or totally disabled men of rank and file of the Auxiliary R.A.M.C., and 299 children, nearly all orphans; the total amount awarded was £7,819. As in both cases the majority of the children are young, and the primary object of the Funds is to assist in education, the Funds' work will not be completed for several years. The Committee hopes to be able to maintain these grants and will be grateful for continued help. The President is Lieut.-General Sir John Goodwin, D.G.A.M.S.; the Hon. Treasurer is Colonel C. Mansell Moullin, R.A.M.C.(T.); and the Hon. Secretary Colonel Sir W. Ha'e-White, R.A.M.C.(T). The office is at 11, Chandos Street, Cavendish Square, London, W.1.

The annual meeting of the Funds was recently held at 11, Chandos Street. In the absence of the President, Colonel William Collier, a Vice-President, occupied the chair. Since the last annual meeting £1,778 has been granted to help the maintenance of the orphans of 35 officers in the Auxiliary R.A.M.C. who lost their lives as a result of the war; and £2,471 has been granted in the same way to the widows and orphans of 96 of the rank and file, making a total of £4,249 granted, and 135 cases relieved in a single year. As frequently several children of a single case were relieved, the total number of persons relieved was considerable.

DEATHS IN THE SERVICES.

COLONEL PATRICK ALEXANDER WEIR, Bengal Medical Service (retired), died at Bueks, on April 23th. He was born on June 1874, of the Rev. James Weir of Drainie, Elgin, and educated at Aberdeen, where he graduated M.B. and C.M. with first-class honours in 1894, and at Guy's Hospital. He entered the I.M.S. as surgeon in September, 1895, became colonel in 1935, and after five years' tour of office as Inspector-General of Civil Hospitals in the Central Provinces, retired in October, 1910. He served in the Afghan war of 1878-80, receiving the medal. Along with the late Lieut.-Colonel J. Crofts, I.M.S., he was the author of *A Medical topographical Account of Kobak and Jhalawar*.

men he was extraordinarily gentle, and I have often watched him wait his opportunity to drop into a discussion the exact word which brought together two disputants who had failed to understand one another. With him all conversation was constructive; he disliked barron argument or talking for effect and mastery.

He was an unusually trustworthy critic of the work of others; his opinion was sought by the most diverse persons and administrative bodies, and his verdict was given without hesitation. When he praised he carried immediate conviction; and his rare interventions in the debates of a committee of which he might happen to be a member were always effective.

His strongest characteristic was his intellectual rectitude, for he was never afraid to face the consequences of any view he might hold, and was always prepared to yield to cogent contradictory reasons. Whatever course of action he undertook was approached with the same quiet intensity; however adventurous might be his opinions, he wasted no time in tilting at windmills. The loss to science and to the university caused by his death is irreparable; for he aroused in those who came into contact with him a passionate consciousness of the significance of life and the beauty of organized knowledge.

R. C. ELSWORTH, M.D., F.R.C.S.,

Consulting Surgeon, Swansea General Hospital.

WE have, with much regret, to record the sudden death on May 27th, at his residence in Swansea, of Dr. R. C. Elsworth, in his 64th year.

Richard Cogswell Elsworth was born in Carlisle, received his medical education at Edinburgh, and graduated M.B., C.M. in 1888 and M.D. in 1901; he took the diploma of M.R.C.S. England in 1891 and that of F.R.C.S. in 1896. He had been in practice in Swansea for more than thirty years, and was surgeon, and afterwards consulting surgeon, to the Swansea Hospital. He was a member of the Swansea Division of the British Medical Association, and in 1903 contributed to our columns a paper on Froyer's operation for enlarged prostate. He held a commission as major in the R.A.M.C. (Territorial), and during the war worked at the 3rd Western General Hospital, Cardiff.

We are indebted to Dr. H. A. LATIMER, now of Tunbridge Wells but for long Dr. Elsworth's colleague on the staff of the Swansea General Hospital, for the following tribute to his memory:

By the sudden death of Dr. R. C. Elsworth, on May 27th, Swansea and a large district in South Wales have been deprived of the services of a brilliant surgeon, and many friends, among whom I am proud to number myself, are left to deplore the loss of a man who had endeared himself to them by his kindness, skill, and willing assistance in their time of need. I am led to make this personal allusion because I am left his debtor for an operation on myself, of a grave character, which he performed some years ago, and for other acts of professional friendship of great value to me.

Dr. Elsworth was educated at the University of Edinburgh, where he acted as assistant to the late Sir Thomas Fraser, F.R.S., Regius Professor of Medicine, and subsequently as a demonstrator of anatomy at that school. From Sir Thomas Fraser, who was one of my colleagues on the General Medical Council, I learned of the high appreciation he had of my friend—an appreciation which was the result of his observation of his work when under him.

The careful study which Dr. Elsworth pursued at his famous university and the opportunities it afforded him made his diagnostic skill one of distinction, and I have no doubt that his post as a demonstrator of anatomy paved his way to the singularly rapid and brilliant handicraftsmanship which marked his career as a surgeon, and led to his enjoyment of a large consulting and operating practice in the region of his adoption. This power of using his hands was exhibited in various directions—in photography and in general mechanics. I need hardly say how valuable a thing it is for a surgeon to be endowed with such gifts, for if to diagnostic acumen is conjoined a power of manipulation of instruments and a consummate knowledge of anatomy we have the highest qualities of a surgeon exhibited in one man.

Dr. Elsworth's death at the comparatively early age of 63 was due to his exhausting work during the great war, and he is one of many members of our profession who have fallen in the exercise of their duties to the State during the years of stress caused by that terrible conflict. I have known of

several such cases where the work in "carrying on" during those eventful years sapped all the powers of life and left men worn out by their exertions. He joined the R.A.M.C. at an early stage of the war, and, in addition to his work in Swansea, had the charge of a large hospital at Cardiff, which he visited three days a week. His responsibilities were great, and he coped with them with characteristic energy, but the strain was immense, and I do not doubt that he has fallen a victim to it.

A COLLEAGUE in Swansea sends us the following appreciation:

Looking back on Dr. Elsworth's career, what struck one most of all was his almost superhuman physical and mental energy. The pace at which he got through a heavy morning's work at the hospital astounded anyone watching him for the first time; every movement was crisp and full of purpose—no hesitation, nothing slipshod, everything looked so very easy. But those who knew him realized that his wonderful quickness of hand and mind were both attributable to years of assiduous hard work and practice in his early days as demonstrator in the dissecting room at Edinburgh University, and later to the constant thought and close reasoning brought to bear in perfecting his surgical technique in general and his manipulative dexterity in particular. When gastro-jejunostomy was in its infancy he spent many an hour at home getting into touch with his needle and thread. While others talked he would be stitching away at pieces of cloth laid over the arm of his easy chair. "Woman's work," he called it, but just an instance of the sound foundations on which his somewhat unorthodox methods rested.

Starting in Swansea first of all as a general practitioner, he was soon able to devote himself entirely to surgery and to build up a well-merited and widespread reputation as a consultant. In these parts of the country a consultation or an urgent operation may mean a journey of anything up to two hundred miles. There are probably few roads in South or West Wales over which Dr. Elsworth has not driven his car by day or night. His hospital patients always came first. Never mind how urgent or attractive the call he would never be tempted to leave till his task in the wards or operating theatre was finished. His hospital work he used to tell us was his religion; never sparing himself, he tolerated no slackness on the part of his assistants. Like most men of his sturdy type he had the power of infecting all around him with his untiring energy and concentration, and of the many men who as house-surgeons came under his influence there must be few to-day who do not realize that they owe some part of their success to the inspiring example and teaching of Dr. Elsworth.

During the war Dr. Elsworth served with characteristic enthusiasm on the staff of the 3rd Western General Hospital at Cardiff. This extra call on the energies of a man who was already overworked was undoubtedly responsible for the cardiac and vascular troubles that brought about his sudden death. These were strenuous times for all doctors left in this country, and men carried on in a spirit that was hardly less heroic than that shown by their comrades overseas. The writer recalls one day that well supports this suggestion. Those of us who travelled to Cardiff with Dr. Elsworth could not help noticing that he looked ill—he had a septic finger and was evidently in pain and fit only for his bed. On arrival at the Military Hospital he collapsed in a long faint and had eventually to be carried back to Swansea in a motor car. That evening he was for some time in a critical condition; he took an anaesthetic and his finger was freely incised. He got back into harness far too soon, well knowing that this breakdown had left its mark, but in spite of all his friends could do he refused to take things more easily; he went ahead with indomitable pluck and finished his life as no doubt he would have wished it—quickly, and with no distressing days of inactivity.

ARTHUR HENRY ROBINSON, M.D. DURHAM,

Medical Superintendent, St. Mary (Islington) Infirmary.

ALL who knew Dr. Arthur Henry Robinson, medical superintendent of St. Mary (Islington) Infirmary, will have heard of his death with deep regret. It took place on May 31st, in his 68th year. He was about to retire from his appointment, but his death was, we believe, unexpected. He received his medical education at University College, London, took the diploma of M.R.C.S. in 1878, graduated M.B. Durham in the same year, and proceeded to the degree of M.D. in 1880. Soon after graduating he became resident surgeon and pathologist

to the Royal Infirmary, Hull, and surgeon to the Hull Dispensary, but for the greater part of his active life he had held office in various Poor Law infirmaries. He was appointed medical superintendent of the Mito End Infirmary in 1885, a post which he held for fifteen years; on resigning it he received a gratifying presentation from the staff. He was the first medical superintendent of the new St. Mary (Islington) Infirmary, which was opened by the present King and Queen, then Duke and Duchess of York, in July, 1900. To Dr. Robinson, therefore, fell the task of organizing the medical work, which he afterwards superintended down to the time of his death. He joined the Royal Artillery early in life, and when he eventually retired with the rank of surgeon-colonel he received the Volunteer Decoration. During the war he was officer in charge of the Highgate War Hospital.

Dr. Robinson kept himself well abreast of the progress of medicine and surgery, and contributed several papers to the *Transactions* of the Clinical, Pathological, and Medico-Chirurgical Societies, and to the medical press. He also issued a translation into English of Calot's book on orthopaedics. He was a kindly man who, having chosen his sphere of work, gave to it the best that was in him, finding recreation in literature and the study of medical history. He made many friends, by whom his memory will be held dear. The funeral took place from St. Peter's Church, Dartmouth Park Hill, on June 3rd. The very large attendance at the service included representatives of the Islington Board of Guardians and of the staff of the infirmary. Among those present was Mr. Walter Schroder, coroner for Central London, who at the Islington coroner's court on the same day bore testimony to the keen interest Dr. Robinson took in his work and his anxiety that patients in the infirmary should be treated with the highest skill and the greatest consideration.

PROFESSOR LAVERAN.

THE death of Professor Laveran removes one of those who at the end of the nineteenth century laid firmly the foundations of tropical medicine. He was president of the Academy of Medicine in Paris when it celebrated its centenary in December, 1920, and his friends believe that the preparations for that event and the celebration itself overtaxed his strength, for he never afterwards returned to work.

Charles Louis Alphonse Laveran was born in Paris on June 18th, 1845, the son of a military medical officer, who was at that time professor, and afterwards became director, of the French military medical school at Val-de-Grâce. Following in his father's footsteps, Laveran became a student at the military medical school at Strasbourg in 1863, held resident appointments in the hospitals of that city, and in 1867 took his degree with a thesis on the regeneration of nerves. In 1874 he won the position of professeur agrégé at the Val-de-Grâce school, and at the termination of that appointment in 1878 was sent to Algiers, where he served at Bône and Constantine; it was at the latter place that on November 6th, 1880, he first observed the haematozoon in the blood of a patient suffering from malaria. In a little book, scarcely more than a pamphlet, he described the various forms of the parasite as he had observed them in the blood, and illustrated his description with excellent fresh drawings. At a still earlier date certain writers had suggested that yellow fever was carried by mosquitos, and it was, we understand, a suggestion made by King in America in 1883, to the effect that mosquitos played some part in the etiology of malaria, that first turned Laveran's attention to the hypothesis, which in the following year he himself adopted. In that year, however, Laveran was appointed professor of military hygiene and clinical medicine at Val-de-Grâce, and his opportunity of personally verifying the hypothesis was lost.

After ten years' occupancy of the chair at Val-de-Grâce and three years in a similar position at the military medical school, Laveran retired from the army and joined the civil service, in which he afterwards became professor of military hygiene at the Val-de-Grâce.

Laveran resumed his researches with regard to the haematozoa of malaria, and studied the parasitic sporozoa of animals. In much of this work he was associated with F. Mesnil, who helped him in the application of the experimental method in the problems with which he was concerned. Laveran published the first edition of his treatise on malaria in 1898 and issued a second in 1907. In 1904 he published in collaboration with Mesnil

a book of over 400 pages on the trypanosomes; the second edition, issued in 1912, contained over 1,000 pages. For the next five years he gave himself mainly to the study of leishmania and the diseases produced by these organisms, a subject on which he published a treatise in 1917.

Laveran received many honours in his own and foreign countries; he was a member of the Académie des Sciences, president of the Société de Pathologie for twelve years, received the Nobel prize in 1907, and was elected a foreign Fellow of the Royal Society of London in 1916. He was an unremitting worker, and for forty-two years devoted all his energies to the study of pathogenic protozoa and their relation to disease in man and animals.

The death of Dr. FREDERICK TURTLE on June 6th at Kirkcubright, Woodford, removes a veteran member of the medical profession. He was born as long ago as 1833 at Newcastle-under-Lyme, and was apprenticed, as was the custom in those days, to Dr. Tom Foster of Manchester. Subsequently he came to London and proceeded with his medical curriculum (which at that time consisted of three winter and two summer sessions) at the Middlesex Hospital. He obtained his first qualification, M.R.C.S. Eng., in 1855, and took the L.S.A. a year later. He held the posts of House-Surgeon at the Royal Free Hospital, and Resident Medical Officer to the Marylebone Infirmary. At the former institution he was associated with the late Thomas Henry Wakley, F.R.C.S., one of the sons of Thomas Wakley, founder of the *Lancet*. He graduated M.D. St. Andrews in 1862. After a short time in practice at Lamberhurst and Collett Place, E., Dr. Turtle succeeded the late Dr. Dachesne at Woodford in 1866, where he continued in active practice until 1902, a period of thirty-six years. Sympathetic in disposition, always a very energetic man, and gifted with an extraordinary natural memory, he conducted successfully a very large practice, and managed at the same time to keep up with current events in medicine. When he was a student, in the fifties, the clinical thermometer and stethoscope were not in general use; the short clinical thermometer was introduced in 1868 by Sir Clifford Allbutt. Dr. Turtle retired from practice twenty years ago, but retained his energy and excellent health until a few weeks ago, still finding interest in the new discoveries in medicine, and could occasionally be found reading in the Library of the Royal College of Surgeons. He was twice married and leaves a family of three sons and two daughters, two of the former being members of the medical profession. The funeral was attended by four medical men bearing his surname: Dr. F. W. Turtle and Dr. G. de B. Turtle (sons), Dr. James Turtle and Dr. W. R. M. Turtle (great-nephews).

Universities and Colleges.

UNIVERSITY OF OXFORD.

Rollston Memorial Prize.

THE Rollston Memorial Prize at Oxford, which is open to graduates of Oxford and Cambridge, for certain conditions, for original research in any branch of natural and vegetable morphology, and for the discovery of new species, was awarded to Gavin R. de Beer, B.A., D.Phil., of the University of Oxford.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 9th the following medical degrees were conferred:

M.D.—N. G. Horner, H. W. C. Vines.
M.B., B.Ch.—W. F. Eberle.
M.B.—H. E. Cresswell.*

* Admitted by proxy.

UNIVERSITY OF LONDON.

APPLICATIONS for the Sir William Dunn Chair of Pathology, tenable at Guy's Hospital Medical School, salary at least £1,500 a year (no pension), must be received by June 22nd.

Dr. Doris Mackinnon has been appointed examiner in general biology at the first examination for medical degrees in July, 1922, in place of Professor A. Dendy resigned.

The following have been reappointed for the first and second examinations for medical degrees in 1922-23 (the chairmen of the respective asterisks):

Chemistry: Mr. H. C. H. Condy* (London Hospital Medical College) and Mr. J. A. Gardner (St. George's Hospital Medical School, London School of Medicine for Women, and Physiological Laboratory), together with the

two external examiners. *General Biology*: Dr. F. Drabble* (Northern Polytechnic Institute) and Dr. Doris MacKinnon (King's College), together with the external examiners. *Physics*: Mr. F. Womack* (St. Bartholomew's Hospital Medical College) and Mr. J. H. Brinkworth (St. Thomas's Hospital Medical School), together with the external examiners. *Anatomy*: Professor W. Wright* (London Hospital Medical College) and Professor E. Barclay-Smith (King's College), together with the external examiners. *Physiology*: Professor H. E. Roaf (London Hospital Medical College) and Professor W. D. Halliburton (King's College), together with the external examiners. *Pharmacology*: Dr. F. Hamill (St. Bartholomew's Hospital Medical College) and Dr. V. J. Woolley (St. Thomas's Hospital Medical School), together with the external examiners (Professor F. Ransom*).

The following footnote has been added to the regulations for the M.D. Examination (Branch III) for internal and external students:

In view of the similarity in the subjects of the examination for the M.D. Degree in Branch III under the regulations for December, 1922, and subsequently, and the subjects of the examinations for the diploma in psychological medicine, candidates are warned that the standard of the examination for the M.D. degree in psychological medicine is distinctly higher than that of the examination for the diploma in psychological medicine.

In connexion with the correspondence between the War Office and the University regarding the recruiting for general hospitals of the reconstructed Territorial Force, a conference was held on February 15th, when the Vice-Chancellor submitted to the Director of Medical Services a series of revised questions which, together with the replies thereto, were submitted to the Senate, which, at its meeting on May 24th, passed the following resolutions:

- (1) That the Senate express their appreciation of the courtesy of the War Office in the arrangement and conduct of the conference which took place on February 15th, 1922, and in the subsequent negotiations; and that they express their willingness to co-operate in a scheme for recruiting the personnel of the reconstructed Territorial Force General Hospitals in accordance with the scheme outlined in the revised answers to the questions which were submitted with the Vice-Chancellor's letter to the Director-General, Army Medical Services (February 21st, 1922).
- (2) That the War Office be informed that the Senate would also be willing to co-operate in a similar scheme respecting the provision of personnel for home hospitals, which it is understood is now in contemplation.

The Vice-Chancellor, Sir Sydney Russell-Wells, has been appointed chairman of the Anglo-American English Conference Committee; and Professor Sir John Rose Bradford, K.C.M.G., C.B., vice-chairman of the University College Committee.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An Ordinary Council was held on June 8th, when Sir Anthony Bowlby, President, was in the chair:

Diploma of Fellowship.

Diplomas were granted to the following twenty-four candidates found qualified for the Fellowship at the recent examination:

F. J. Anderson	W. B. Foley	F. T. Parker
Alice Bloomfield	W. A. Hewitson	B. H. Pidgecock
J. F. C. Braine	S. L. Higgs	B. T. Roso
D. J. Browne	T. G. Jones	J. P. Ross
R. S. Corbett	W. McK. H. McCullagh	J. Victory
I. W. Corkey	G. Massie	H. M. Wharry
E. A. Crook	C. H. Medlock	W. E. Wilson
A. R. Dingley	D. F. A. Neilson	H. B. Yates

Election of Examiners.

The following were elected Examiners for the Fellowship for the ensuing year:

Anatomy: Arthur Ralph Thompson, John Ernest Sullivan Fraser, Gordon Gordon-Taylor, William Frederic Haslam. *Physiology*: Arthur Rendle Short, John Mellanby, David de Souza, Frangcon Roberts.

Conjoint Examination.

The Committee recommends the Council to elect the following candidates as the Examiners to be appointed by this College under the Examining Board in England for the ensuing year:

Elementary Biology.—Thomas William Shore, James P. Hill. *Anatomy*.—Frederick Gymer Parsonson, Herbert Eldon Roaf, Cuthbert Lockyer, George Farley Lancelot Holland, William Andrewes, Francis and Hygiene. *Bacteriology and Hygiene of Tropical and Subtropical Regions*.—Sir John Herbert Parsons, Malcolm Willoughby Lytle, Malcolm Langton Hepburn. *Diploma in Psychological Medicine*.—Sir Frederick Mott.

Examinership in Dental Surgery.

The President reported that Mr. W. H. Dolamore's term of office on the Board of Examiners in Dental Surgery would expire on July 25th next, and that the vacancy thus occasioned would be filled up at the Ordinary Council on July 27th.

GENERAL LUDENDORFF has recently received the honorary title of doctor of medicine from the University of Königsberg.

The University of Jena has conferred the honorary degree of Doctor of Medicine on Dr. Otto Henken, director of the department of optical instruments in the Zeiss factory.

Medical News.

The annual meeting of the Durham University Medical Graduates' Association will be held at 11, Chandos Street, Cavendish Square, London, W., on Thursday, July 6th, at 5 p.m. The annual dinner will be held at the Café Royal, Regent Street, W., at 7.30 p.m. on the same day. Tickets, price 15s., excluding wines, may be obtained from the Honorary Secretary (South), Dr. J. K. Haworth, St. Mary's Hospital, W.2. All medical graduates of the university are cordially invited to the dinner.

The summer meeting of the British Orthopaedic Association was attended by Sir Robert Jones, the President, and about forty members and visitors. It was held on Friday and Saturday, May 26th and 27th, at Sir William Treloar's Hospital for Crippled Children at Alton and at its annexe at Hayling Island. At Alton a lantern-slide demonstration was first given, showing in general the methods of treatment in the hospital, and a cinematograph of the application of a high plaster jacket. The college in which the technical training of crippled boys between the ages of 14 and 18 is carried out was then inspected; the principal trades taught are leather bag, case, and trunk making, tailoring, and boot making and repairing. A series of cases illustrating mechanical methods of treatment of spinal caries and hip disease was shown in the afternoon. On Saturday the association paid a visit to Hayling Island, where treatment by fresh air, sunlight, and sea bathing was demonstrated, and Professor Leonard Hill gave a short lecture on the physiological effects of sunlight.

The late Sir Patrick Manson has left estate of net personality of £57,085. He has bequeathed his medical library and scientific instruments and apparatus to Dr. Philip Manson-Bahr, and the residue of his property, subject to his wife's life interest, to his children or their issue in equal shares, directing that the share of his son David should be retained on trust for his said son and his wife and issue, and failing issue to his son David he left the reversion of his portion to the London School of Tropical Medicine in connexion with the Seamen's Hospital Society to conduct investigations into tropical diseases, such investigations to be conducted abroad as far as possible.

Mr. VICTOR BONNEY will resume his "gynaecological talks" under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association, on Saturday, June 17th, at 12 noon, at the house of the Royal Society of Medicine, 1, Wimpole Street.

MEMBERS of the British Medical Association who play bowls will be interested in the announcement, in this week's SUPPLEMENT, of an international bowling match that has been arranged to take place on July 27th during the Annual Meeting at Glasgow.

DURING the annual general meeting of the Eugenics Education Society a conference on "The inheritance of mental qualities, good and bad," will be held at the rooms of the Royal Society, Burlington House, Piccadilly, on Tuesday, July 4th, at 5.30 p.m. The speakers will include Dr. Tredgold and Dr. C. Hubert Bond.

IN accordance with the proposal made in our correspondence columns on May 27th, p. 859, a society to be known as "The Medical Society for the Study of Venereal Diseases" was formed at a meeting held at the house of the Royal Society of Medicine on June 9th. Dr. David Watson of Glasgow, who presided over an attendance of about twenty-four, said that the object of the society would be to bring together for the reading of papers and discussion the many keen spirits now engaged in work upon venereal diseases. A formal motion to establish such a society was moved by Dr. Wilfrid Fox of St. George's Hospital, seconded by Dr. Alexander Wilson of Manchester, and carried unanimously. Some discussion took place as to whether the society would not gain its ends better by becoming a Section of the Royal Society of Medicine, but the feeling of most of those who spoke appeared to be in favour of independence; a final decision was postponed until the society had been got into working order. Certain rules were agreed to, including one which laid it down that the society should not express its corporate views on any subject of administrative or political interest, unless invited to do so by a department of the Government, and that in the event of any such invitation the views expressed should be those of 80 per cent. of the members voting on a referendum. It was also stipulated that the society should be composed exclusively of regularly qualified medical practitioners. It was agreed that the annual subscription should be 10s. 6d., but that if hereafter a journal was started it should be two and a half guineas. The Chairman said that as the cost of publishing a monthly

Journal would be £500 or £500 a year, a membership of over 200 would have to be ensured before this responsibility could be shouldered, and the question was remitted to the council which is to be formed. The annual general meeting will be held each year in July, and the Chairman suggested that the same town and the same time might be chosen as those of the annual meeting of the British Medical Association. Local divisions of the society are to be formed and to appoint their own officers and hold meetings for the discussion of matters of clinical and administrative interest. Each division will also have two representatives on the council. The nucleus of a council was formed, and Dr. Robert Forgan, who has acted as secretary of the provisional committee, agreed to continue in that capacity until the first regular meeting of the society in July.

The next meeting of the Medical Officers of Schools Association will be held at the house of the Medical Society of London on Monday, June 26th, at 5 p.m., when a discussion on the public health problem raised by children suffering from cardiac disorder will be opened by Professor F. S. Langmead, Dr. W. P. S. Brauns, and Dr. James.

As already announced, a graduate course on children's diseases, under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association, will be held from July 3rd to 8th at the East London Hospital for Children, Paddington Green Children's Hospital, Victoria Hospital for Children, Chelsea, Queen's Hospital for Children, the Middlesex Hospital, and St. Marylebone General Dispensary. The syllabus may be had from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

PROFESSOR GEORGE H. F. NUTTALL, F.R.S., of Cambridge, has been elected a corresponding member of the Société de Biologie, Paris, and of the Society of American Bacteriologists.

The next post-graduate lecture at the Royal Society of Medicine, under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association, will be delivered by Professor H. MacLean, on "Recent work on albuminuria and glycosuria," on Monday, June 19th, at 5 p.m.

The sixteenth French Congress of Medicine will be held in Paris from October 12th to 14th under the presidency of Professor F. Vidal, when the following subjects will be discussed: (1) Diagnosis between gastric and duodenal ulcer, introduced by Drs. Enriquez and Davand of Paris and Drs. Cramer and Saloz of Geneva. (2) The pathological significance of the abnormal forms of leucocytes, introduced by Drs. Sabrazès of Bordeaux and Lemaire of Louvain. (3) Prophylaxis and treatment of deficiency diseases, introduced by Drs. Weill and Mouriquand of Lyons and Rathery of Paris. Further information can be obtained from the general secretary, Dr. A. Lemerle, 217, Rue du Faubourg St. Honoré, Paris.

DR. T. GERALD GARRY, of Cairo, who a couple of years ago contributed to our columns a short account of Pistany (Bad Pöstyén), then stated that the mud used for the baths had a natural temperature of 140° F. He now writes to point out that Pistany is the only mud bath in Czechoslovakia which is naturally warm. The mud baths used at other places are, he states, artificially heated.

The seventh annual meeting of the National Council for Combating Venereal Diseases will be held in the Robert Barnes Hall, 1, Wimpole Street, W.1, on Monday, June 19th, at 4 p.m. The President, Lord Gorell, will give a valedictory address.

To the memory of Dr. Just Lucas-Championnière, who was one of the first French surgeons to study Lister's practice in Glasgow and by his example and persistent advocacy introduced the antiseptic system into France, a monument has been erected in the courtyard of the Hôtel-Dieu, Paris, at the entrance to the department he directed for so many years. The monument is the work of Professor Paul Richer, and was unveiled by M. Strauss, the Minister of Hygiene.

THE celebration of the Bretonneau centenary has been postponed from June to October. The exact date will be announced later.

At the International Congress of Otolaryngology, to be held, as already announced, in Paris from July 19th to 22nd, there will be an exhibition of normal and pathological preparations, and also, we are informed, an exhibition of instruments, ancient and modern, associated with both otology and rhino-laryngology. The Faculty of Medicine is providing large rooms for the exhibition, and objects should be sent by June 20th, addressed to Drs. Mahu and Truffert, Faculté de Médecine, Rue de l'École de Médecine, Paris.

DR. LUCIEN CAMUS and Dr. Louis Martin of Paris have been made corresponding members of the Royal Academy of Medicine of Brussels.

THE Royal Society of Medical and Natural Sciences of Brussels will celebrate its centenary on June 22nd.

A POST-GRADUATE course in practical surgery will be held at the Salpêtrière Hospital, Paris, from June 19th to July 3rd, under the direction of Professor Gosset; the fee is 150 francs, and particulars may be had from the secretary of the Faculty of Medicine, Paris.

THE annual "Voyage d'Études Médicales" will start on August 26th and end on September 6th, under the direction of Professor Paul Carnot. The party will visit Bordeaux, Arcachon, Dax, Biarritz, Salies-de-Béarn, St-Jean-de-Luz, Cambo, Pau, Saint-Christin, Eaux-Chaudes, Eaux-Bonnes, Angèles, Lourdes, Canterets, Luz, Saint-Sauveur, Gavarnie, Bagnères-de-Bigorre, Luchon, and Toulouse. The subscription is 682 francs for the tour from Arcachon to Luchon. Application should be made to the secretary, Dr. M. Gerst, 94, Boulevard Flandrin, Paris.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attilogy*, Westrand, London; telephone, 2530, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2530, Gerrard.

QUERIES AND ANSWERS.

SURGEON REAR ADMIRAL W. EAMES, R.N.(ret.), writes: In reply to "T. I. M." I recommend West Southbourne, situated about five miles east of Bournemouth. It has pretty surroundings and a climate which is very salubrious, and has been described as "life-giving."

OXURIS.

"J. M." writes: If Dr. Hackworth's patient can have his appendix removed I think he will not experience any difficulty later in expelling the oxyuris. Threadworms find in the appendix a safe asylum when measures are taken to expel them. In the intervals of treatment they come forth again. The appendix being inaccessible during the course of treatment, the best plan would be to remove it, and later again attempt one or other of the usual measures.

DR. C. E. PRATT, Assistant R.M.O. Bermondsey Medical Mission, writes: In reply to Dr. V. C. Hackworth's question about threadworms in a girl of 11, may I give you the routine treatment carried out at this clinic, where we get a great many cases, some

Our treatment is as follows:
ent, such as liquorice or syrup of white at the clinic. The mother receives two powders, each consisting of equal parts of calomel and santalin (for a child of 11 we should give calomel gr. j, santalin gr. j), and also a bottle of liquid paraffin. With these she has a paper of written directions, which are carefully read over and explained to her. They are as follows:

1st day: No solid food after 5 p.m. A cup of milk at supper time.
2nd day: At 7.30 a.m. give the first powder, a drink of hot milk, and keep the child lying down. Light diet all day.
3rd day: Treatment as on 1st day.
4th day: Treatment as on 2nd day.
5th day: Ordinary food. Give liquid paraffin 5ij at bed time.
Continue the liquid paraffin 5ij every night for a fortnight. If worms still remain, treatment is begun again. Stools to be most carefully examined.

These directions are simple and very explicit, as they have to be in a district such as this, but our results have been very successful. The great thing is to get the mothers to persevere with treatment.

TREATMENT OF PSORIASIS.

"A. B. S." writes: A man, aged 47, has had generalized psoriasis for about sixteen years. At present the rash is red, raw, and angry-looking. Almost the whole of the skin from the waist downwards is affected, and also the arms from the elbows downwards. The disease has cleared up several times of its own accord during the sixteen years he has been troubled with it, but for the last four years he has had it constantly, and for the last six months he has been quite unable to work, owing to the burning and irritation of the parts affected. The rash used to be scaly, but there is very little scale formation now. In spite of vigorous chrysarobin treatment, oil of cade ointment, etc., he is getting worse. Even arsenic internally in large doses has been given a trial. Suggestions as to definite curative treatment will be thankfully received, as the poor man's condition is pitiable.

POTASSIUM PERMANGANATE IN HAEMORRHAGE.

DR. V. N. MEHTA (Viramgam, Bombay Presidency), writes to say that in an obstinate case of epistaxis which had resisted other methods the bleeding was immediately arrested by irrigating the nose with potassium permanganate solution, 20 grains to the pint. He adds that finely powdered crystals of the salt applied over the bleeding surfaces act as a very good haemostatic in minor operations.

INCOME TAX.

"R. H." was assessed for 1921-22 on the sum of £2,230, the average amount of the previous three years' profits. His profits for the year ending April 5th, 1922, were actually £1,130. Can he claim any reduction of the assessment?

* A reduction to the amount of the year's profits can be claimed only if (a) the practice was set up later than April 5th, 1919, or (b) "R. H." has succeeded to the practice since that time and suffered in his professional earnings from some specific cause—for example, the coal strike of last summer.

"C." makes the following inquiry: B. joined A. as one-third partner in October, 1919; for the six months to March, 1920, B. paid tax on one-third of one-half of the total cash receipts, including back debts in which he did not share. In March, 1922, the partnership between A. and B. was dissolved, leaving A. in the practice. Should B. pay income tax to A. on back debts received after the dissolution of the partnership?

* No; unless this is specifically provided for in the partnership deed. Payment of tax on the basis of cash receipts is a convenient method of meeting income tax liability, but those payments refer to the earnings of the period for which the assessments are made and not to the earnings in respect of which the cash is received. B. has apparently paid tax in respect of his earnings for the period from October, 1919, to March, 1922—except as regards the instalment due in July, 1922—and has no further liability.

"M. F. G. M." qualified in October, 1920, and commenced work as an assistant in November, 1920, earning £150 for the period to April, 1921. From then to April, 1922, the earnings were about £350. On what amount is he liable for the year 1921-22?

* The amount assessable is determined by the earnings of the first twelve months; our correspondent cannot take the amount for the year to April 5th, 1921, as the basis for the following year, because he did not commence work as an assistant until November, 1920.

"D. E." is one of three partners who pay their own locomotion expenses, expended £203 for car renewal in 1920 apparently, but has been allowed £67 only on the assessment just received.

* It has to be remembered that the renewal of a car is allowable as a professional expense, and that the basis of assessment is the excess of receipts over expenses on the average of three past years. For these reasons the full £200 cannot be claimed as a specific deduction for any financial year; it is only an item of expense in the determination of the profits for 1920 and consequently affects the 1921-22 assessment by one-third of £200 = £67 only. The converse, of course, would arise in the event of the receipt of any unusually large fee in any particular year.

"W. V. M." was demobilized in March, 1920, took up a position as assistant in October, 1920, and became a partner in October, 1921. On what basis should his declarations be made?

* (1) For the year to April 5th, 1921, on the actual earnings of the year or on the average earnings of the three previous years, whichever is the less, and (2) for the year to April 5th, 1922, as regards the first six months on the earnings of that period, and as regards the second six months, on the basis of the income tax assessment—that is, if he has, say, one-third share of the partnership, profits as from October, 1920, then he would return for that half-year one-half of one-third of the amount assessed on the practice for 1921-22.

LETTERS, NOTES, ETC.

RHYTHMIC IRREGULARITY OF THE HEART.

DR. GEORGE H. VOS (Tottenham, N.) states that he has for over thirty years attended a lady, now aged 82, who has always had fair health, but has a gouty diathesis, as evidenced by the joints of hands and feet. When the pulse is counted five beats occur, then a pause, and then five more beats. If he keeps her interested in conversation the pulse becomes continuous, but the groups of five beats return when she becomes quiet. No murmurs can be heard. Our correspondent asks for an explanation.

COCKROACH IN THE NASAL PASSAGES.

DR. ARTHUR SHEARD (Huddersfield) writes: While at sea in the Mediterranean, on March 18th, 1922, I first noticed that I had contracted what I thought to be a slight "cold in the nose," characterized by a tendency to spit up mucus, and also occasionally to eject a small plug of tenacious mucus from the right nostril on forcibly blowing the nose. I experienced no real sense of irritation—in fact, the discomfort was so slight that I thought nothing of it at the time. There was no obstruction to breathing through either nostril. On the evening of March 19th, when composing myself to sleep, my head had no sooner reached the horizontal position than I experienced a slight fullness in the left nostril, suggesting that more mucus required to be discharged. Accordingly I closed the right nostril and blew forcibly, but this action increased the irritation to an acute "tickling" sensation, which at once caused an involuntary flow of tears from both eyes. There was no obstruction to breathing through either nostril, and digital examination of both nostrils failed to reveal anything. On cessation of the blowing of the nose the irritation ceased, so I dismissed the occurrence from my mind and slept soundly.

At 4.45 a.m. next morning I awoke with the recollection of having had a vivid dream, an experience which is unusual with me. I lay awake for a few minutes, and then remembered about my difficulty the previous evening, although now I felt nothing unusual in the nose. I again blew the nose forcibly several times, which action brought on a slight sense of fullness in the left nostril, but none of the sharp tickling sensation felt previously. After a few attempts I obtained sudden and complete relief by ejecting something from the left nostril into a handkerchief. After switching on the light, great was my astonishment to observe that I had ejected a full-grown cockroach. It was quite dead, and enmeshed in a film of clear tenacious mucus. Its body measured three-quarters of an inch in length.

The only conceivable time when the cockroach could have entered the nostril must have been during sound sleep, the most recent occasion for which was some twenty to twenty-four hours previous to its ejection. Most probably it had entered two or three days previously, which would account for the slight "cold" which I had experienced. Three features of this incident stand out as remarkable:

1. The entrance of the cockroach into the nose without causing any irritation or disturbance. During sleep I invariably breathe quietly through the nose with the mouth closed.
2. The comparatively long period (probably two days or more) during which the insect remained in the nasal passages without causing any appreciable inconvenience. Not once during this time had I even the desire to sneeze.
3. The ease with which the offending insect was ejected by forcible blowing of the nose.

I may say that cockroaches were a common pest on board my ship, but I have never heard of anyone having undergone an experience similar to mine described above.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 26, 27, 30, 31, and 32 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at p. 232.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 77 Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-restant letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

556. Chronic Diffuse Nephritis in Childhood.

GREENE (*Amer. Journ. Dis. of Children*, March, 1922) reports a case and reviews the literature of chronic diffuse nephritis in children under 10 years of age, with a view to correlating the findings. All cases with a history of scarlatina, or syphilis, or preceding infection, are excluded, only those being considered which present a more or less uniform clinical picture. In most instances symptoms can be traced to the first year of life, or even from birth. Twenty-seven cases from the literature come under review, in 19 of which the clinical and pathological findings are complete, but are not so complete in the remaining 8. Evidence of nutritional disturbance—renal infantilism—were almost invariably noted as appearing towards the end of the first year or on weaning, the children being physically and mentally backward in development, difficult to feed, with in many instances bony deformities and evidences of rickets. Pallor, anaemia, polyuria of low specific gravity, the presence of albumin in relatively small amounts, occasionally oedema, cardiac hypertrophy, and albuminuric retinitis were among the symptoms noted, and uraemia was the terminal condition in nearly all the cases. The pathological findings were similar to those found in chronic diffuse nephritis in adults, the kidneys being small and pale with adherent capsule, both being affected about equally. Glomerular changes depended upon the degree of damage, varying from hypertrophy to connective-tissue infiltration, and the tubules showed epithelial swelling and degeneration. Etiologically the most marked feature was the history in nearly every instance of weakness and delicacy from birth and backwardness in development, pointing to a congenital origin, though the primary underlying cause is obscure.

557. Incipient Epilepsy.

TRACY (*Med. Record*, March 11th, 1922) discusses the diagnosis and treatment of incipient epilepsy, that early stage of the disease manifested by faintings, sudden pallor, dizzy attacks, sudden weaknesses, and periods of irritability associated with a sympathetic hypertonia, unbalanced vaso-constrictor reflexes, and chronic vaso-constriction spots. By the administration of colloidal oenanthe crocata by mouth in three cases the sympathetic hypertonia was overcome, and it was found that as the vaso-constrictor reflexes became normal the symptoms of dizziness, loss of consciousness, sudden pallor, and irritability disappeared. Observations on other cases point to the coincidence of sympathetic hypertonia with the symptoms of incipient epilepsy, and show the concomitant disappearance of the symptoms and of the sympathetic hypertonia by the use of oenanthe crocata. The drug is a sympathetic paralyser, and it is best administered as a colloidal preparation free from alcohol. In cases where a demonstrable sympathetic hypertonia is present in children 10 years old as much as five minims, four times a day (after meals and at bedtime), has been given, but it is advisable gradually to work up to such a dosage. It is safest to start with much smaller doses, giving a teaspoonful of a mixture containing ten minims in eight ounces of water and gradually increasing the strength until the mixture contains two drachms in the eight ounces. Notes of three cases are given, the result of treatment in the first case being amelioration of the symptoms under small dosage during the first month, and their disappearance at the end of the second month under increased dosage. In the second case the medicine was taken very irregularly, the symptoms abating during its administration, but returning when it was omitted. In the third case, in which the medicine was taken regularly for seven months, all symptoms disappeared after the second month, and they have remained absent up to the present, a period of three years.

558. Standard of Cure in Syphilis.

FRASER (*South African Med. Record*, March 25th, 1922), in summarizing the present position as regards the cure of syphilis, points out the uselessness of a few massive doses of arsenobenzene, and confines the value of the Wassermann reaction to diagnosis, since treatment directed against and controlled by it is misapplied, each case being treated as an individual apart from the Wassermann reading. Slow and progressive sterilization must be the aim, the treatment being employed with a view to its power of stimulating tissue to defensive activity in addition to its action on the parasite,

and such treatment should be carried out for two or three years irrespective of the Wassermann reaction. Since at present a cure can only be regarded as relative, patients should be urged to undergo periodic courses of treatment for the rest of their lives if later manifestations are to be successfully prevented. After adequate treatment over a period of two or three years marriage may be permitted, and is not contra-indicated even if the Wassermann reaction is positive, the risk to the wife being very slight provided no late lesions arise. In the event of a married man contracting the disease pregnancy should be avoided until cure has been effected; but in the event of its occurrence the wife should have intensive treatment throughout the pregnancy, and the child be treated for three years, whether symptoms are present or absent, it being borne in mind that the Wassermann reaction in infants is unreliable as a guide. The same rule applies to the marriage of a syphilitic woman as to a man, further treatment being given throughout each gestation, and to the children from birth, since, however completely treated, a syphilitic woman is always liable to give birth to an infected child.

559. Ascariasis of the Bile Ducts.

NEUBÖRGER (*Wien. klin. Woch.*, February 23rd, 1922), who records four cases in women aged from 36 to 63, states that one of the most disagreeable occurrences in the aftermath of the war is the great increase in helminthiasis. Whereas formerly intestinal obstruction due to ascariasis was occasionally observed, the presence of these parasites in the bile ducts was one of the greatest rarities. Among 2,000 operations on the bile ducts Keht did not meet with a single example of this kind, whereas ever since 1914 a large number of cases have been recorded. The clinical picture closely resembles that of acute cholangitis, but is distinguished from it by two symptoms—namely, the onset with violent and continuous pain and a pulse of 120 and more. The temperature is between 100.4° and 102.2°. The pain is situated in the right epigastric region and radiates under the ribs and to the back. Acute cholecystitis and acute pancreatitis are excluded by the softness of the abdominal wall and absence of tenderness on light pressure. If, as in three of the writer's cases, ascariasis have been vomited, the diagnosis of these parasites being responsible for the condition is most probable. Whether the severe toxæmia is due to toxins produced by the worms or by invasion of the common bile duct by the parasites is uncertain.

570. Epileptiform Attacks in Sero-fibrinous Pleurisy.

ACCORDING TO LAUBRY and BLOCH (*Paris méd.*, February 25th, 1922), who record a case in a previously healthy man aged 25, in whom the onset of a sero-fibrinous pleurisy was accompanied by an epileptiform attack, cases of this kind are very rare. Roch of Geneva in 1905 was able to collect only five cases, published by Corazza, Talmon, Camus, Treille, and himself respectively. The development of the attacks, as shown by Roch, is due to inflammatory pleural effusion or even a dry pleurisy having an irritating action on the nerve terminations. Experimental epilepsy has been produced by Roch, Cordier (1911), and Thiroloix, by injection of an irritating fluid (tincture of iodine or ethyl chloride) into the pleura. The vagus conveys the epileptogenous impressions to the nerve centres, as is shown by the fact that double vagotomy or injection of morphine prevents the occurrence of the attacks, while section of the phrenic or sympathetic has no effect. Hence the advisability of giving an injection of morphine before performing thoracentesis, as is the rule in Florand's wards.

571. Desquamation of the Bladder Epithelium in Scarlatina.

GONNELLA (*Deut. med. Woch.*, March 31st, 1922) has wondered whether desquamation of the skin in scarlatina has any parallel in the linings of internal organs such as the bladder, and to elucidate this possibility he has counted the number of epithelial bladder cells from time to time in the urine of sixteen children suffering from scarlatina. The urine passed during the twenty-four hours was centrifugized, and the epithelial cells were counted in a Bärker's chamber. As a control several counts were made of the same specimen of urine, and the results were remarkably uniform. As a further control the urines of eight children, suffering from other diseases, such as pneumonia, were examined in the same way, and in none was any increase in the number of epithelial cells observed. In all but three of the six

cases of scarlatina there was an increase in the number of epithelial cells, but this increase did not always synchronize with the desquamation of the skin. There appeared to be no parallelism in the severity of the external and internal desquamation, but the author's observations definitely point to the existence of internal desquamation in association with scarlatina.

572. Statistics of Liver Diseases.

MÜLLER (*Klinische Wochenschrift*, April 22nd, 1922) thinks that every clinician who has had the opportunity of observing an extensive hospital practice for some years will have been impressed by the change in the frequency of the more important liver diseases. He publishes statistics confirming these general impressions from the wards of the Moabit Hospital, Berlin. The percentages are given of seven forms of liver affections amongst the cases admitted, and these are indicated in two charts (for the period from January, 1914, to March, 1922). The frequency of cancer and of inflammatory diseases of the bile ducts remained unchanged. The frequency of catarrhal jaundice remained much the same from 1914 to 1919; but it became twice as frequent in 1920, and nearly three times as frequent in 1921. Salvarsan jaundice increased in 1921 and 1922. Hepatic syphilis showed little change, but recently has slightly increased. The frequency of cirrhosis of the liver has diminished; in 1921 it was one-third of that in 1914. The difference is probably due to the fact that less alcohol has been recently consumed. Acute yellow atrophy of the liver has increased in frequency recently.

573. Paralysis of Accommodation.

JEANDELIZE (*Revue Médicale de l'Est*, February 1st, 1922) discusses paralysis of accommodation in relation to infectious diseases. He says the three common factors are diphtheria, encephalitis lethargica, and syphilis, and in the presence of symptoms of ciliary paralysis one should think of one or other of these diseases. In the first two the paralysis is mostly bilateral, in the third unilateral. The prognosis in diphtheritic paralysis is usually good. Bilateral paralysis may occur in syphilis, but is uncommon, and there are usually other signs of syphilis which will help to clear up the diagnosis.

574. Calcium in Salvarsan Poisoning.

KENEDY (*Deut. med. Woch.*, May 5th, 1922) confirms the observation of Pulay (*Deut. med. Woch.*, February 16th, 1922) that certain of the toxic symptoms of salvarsan may be avoided by the simultaneous injection of calcium. One of Kennedy's patients was a woman who reacted to even small doses of neo-salvarsan with severe oedema and diffuse inflammation of the skin of the face and limbs, as well as with a temperature of 40° C. Since giving calcium, separately or in the same injection as the neo-salvarsan, he found the patient tolerate the latter without any disturbances. The regularity with which she developed toxic symptoms after neo salvarsan alone, and remained free from the symptoms when it was combined with the injection of a 10 per cent. solution of calcium chloratum, showed that the influence of the latter could not be explained away as accidental.

SURGERY.

575. Non-operative Treatment of Empyema.

GIBBON (*Amer. Journ. of the Med. Sciences*, April, 1922) points out that the experience of the war has considerably modified civilian treatment of septic conditions in the pleura. Acute empyema should now be treated by Carrel-Dakin irrigation, since the painstaking employment of this method will result in the sterilization of the cavity and ultimate cure, and so enormously reduce the cases of chronic empyema. The opening in the chest wall should be made at a point over the collection of pus, in such a way that the cavity can be kept filled with Dakin's solution even when the patient is sitting up or on his feet. A simple intercostal incision is sufficient; it is not necessary to resect a rib, or to remove masses of lymph from the cavity, or to liberate the lung by digital separation of adhesions, for the lung will expand when the cavity is sterilized and closed. The Carrel-Dakin treatment should be applied to the treatment of chronic empyema also, and the author regards the criticism that the treatment is troublesome and requires much attention as groundless, since some of his cases carried out their own sterilization at home, obtaining fresh Dakin's solution from the hospital every two or three days. To obtain success the Dakin's solution must remain in contact with the entire wall of the cavity; the solution must be properly made up and fresh,

and the greatest care must be exercised to prevent reinfection of the sinus and cavity from the skin. In order to estimate the size of the cavity it should be injected with bismuth in oil, with the patient in such a position that the mouth of the sinus is higher than all parts of the cavity; stereoscopic x-ray plates are then taken and the exact position and shape of the cavity determined. Unless there be necrosis of a rib or a foreign body present no operation is necessary, except simple dilatation of the sinus so as to admit two or three Carrel tubes. The cavity is kept filled with the solution, just enough being added every two hours during the day and every three hours during the night to keep it full. The pus first disappears; sinews are then taken from the depths of the cavity and sinus, and when these have been negative for three or four successive days the tubes are withdrawn and the cavity allowed to close without any surgical interference.

576. Statistics of Colles's Fracture.

CONTI (*Schweiz. med. Woch.*, April 20th, 1922) has made a statistical analysis of the 542 cases of Colles's fracture coming within the sphere of the Swiss Accident Insurance in Lucerne in 1919 and 1920. The second decade was the age at which this fracture was most common, and in 24 cases it was a "chauffeur" fracture, the injury in all but one of these cases being indirect and inflicted while the patient was cranking up. The author distinguishes three kinds of "chauffeur" fracture, according as (1) the line of fracture runs obliquely from without, from the styloid process into the radio-carpal joint; (2) the line of fracture runs 1 to 2 cm. above the joint; and (3) the line of fracture runs from the outer side of the distal end of the radius, reaching only to about the middle of the bone. Only in 42 per cent. was the fracture associated with professional work, and in 9 per cent. it was associated with gymnastics. In 94.5 per cent. of the men, and 93 per cent. of the women, complete recovery was effected. In the remainder, in which some degree of deformity persisted, the compensation paid ranged from 10 to 30 per cent. A point which the author emphasizes is the tendency of the doctor in charge to underrate the time required for recovery. This depends much on the age of the patient; in the second decade 4½ weeks are sufficient. From the third to the eighth decade the time in weeks increases from 5½ to 7, 7, 8½, 9, and 18. The average time is 6 weeks, whereas practitioners are inclined to consider 4½ sufficient.

577. Post-encephalitic Blindness without Lesion of Fundus.

F. AGNELLO (*Il Morgagni*, May 5th, 1922) refers to the frequency of ophthalmoplegia and of optic nerve lesions recorded in the recent epidemic. The visual disturbances range from slight amblyopia to total blindness, and in a certain number oedema and congestion of the papilla or pallor with signs of commencing optic atrophy were found. Treatment was of little use. He describes the case of a girl of 13 whose family history was negative. She had had measles and coxema, and several attacks of tonsillitis. Menstruation commenced at the age of 12 with hysterical symptoms and some irregularity of menorrhagia. Her illness began on February 16th, with sudden onset of fever (39.8° to 40.5° C.), intestinal symptoms followed by bronchopneumonia lasting eight days and running a normal course. On February 27th encephalitis supervened with return of fever (38.5° to 39.5° C.), lethargy, ptosis, and strabismus. When the temperature commenced to fall she complained of her eyes, and from the beginning of convalescence she was quite blind. When seen by the author the ptosis and squint had disappeared, but there was slight nystagmus. The pupils were of normal size and reacted promptly to light. The discs and vessels were normal in colour and size, the retinae were normal and media quite clear. The patient could not recognize any objects, and said she was quite blind. Agnello states that Vincent has recorded similar cases with no obvious changes in fundi and preservation of light-reflex. He excludes uraemia and lead poisoning, and suggests that the lesion in this case was in the subcortical white matter of the occipital lobes.

578. Trephine Operations for Glaucoma.

HEPBURN (*Brit. Journ. Ophthalmol.*, March, 1922), from his experience in 140 trephine operations for glaucoma, believes it to be the operation of choice. The importance of an efficient conjunctival flap cannot be overestimated in avoiding late infection, and he strips the conjunctiva off the globe in its entire thickness right down to the sclera, using forceps without teeth to avoid the risk of tearing it. The trephine is rotated so as to cut through the anterior part of the scleral disc before the posterior, to form a hinge posteriorly so that the disc can be removed without fear of injuring the conjunctival flap. The trephine should never be removed until the section is finished, so that the force of the aqueous discharge will push the knuckle of the iris well out of the wound. Cases

operated upon early, especially while the tension was normal, gave the best results, and the operation was only performed in acute glaucoma provided the tension had been previously reduced; otherwise an iridectomy was done. Failure is likely to result in secondary glaucoma, and in long-standing cases where the tension is raised at the time of operation, and when the field has been generally contracted almost down to the fixation point. Vision in many cases often appears worse immediately after operation, but improvement follows later. The trephine operation, undertaken early, with carefully prepared conjunctival flap, is the ideal one for chronic glaucoma, especially of the type met with in young adults.

579. Fracture of the Patella.

ESTON (*Bull. et Mém. Soc. Chir. de Paris*, March 28th, 1922) considers that fractures of the patella due to direct violence from falls on the ground are probably more common than is generally supposed. He reports the case of a man, aged 62, with simultaneous fracture of both patellae due to a fall on the stairs. On the left side there was a transverse fracture at the junction of the middle and lower thirds, whilst on the right side the fracture was at the junction of the upper and middle thirds. The former was due to indirect violence, whilst the latter, he thinks, was due to the fall on the ground. Direct fractures are usually attributed to blows or kicks; in falls it is considered that it is the tuberosity of the tibia, and not the patella, which receives the impact. In reality, in a fall forward on the ground it is the patella which receives the shock, in its lower third, in slight flexion and flexion to a right angle, whilst in extreme flexion it is the upper two thirds. Contrary to general opinion, the anterior tuberosity of the tibia does not touch the ground. These conclusions have been proved by experiments and are confirmed by everyday experiences of infections of the patella bursa in those who have to kneel. Likewise wounds of the knee, so common in children, lie over the patella and not over the tibial tuberosity. These examples show that in flexion of the knee it is the patella itself which touches the ground.

580. The Etiology of Hernia of the Bladder.

WATSON (*Amer. Journ. of Surgery*, March, 1922) finds that the most important causative factors in hernia of the bladder are age and sex, whilst anything that dilates the hernial rings or increases the volume of the bladder favours this disease. It is primarily a condition of adult life and old age, and occurs more frequently in males. Distension of the bladder in prostatic disease or due to urethral obstruction favours the condition; the bladder thus remains enlarged and overfills the hernial orifice, which it may enter. If there follows an exciting cause, such as an effort or strain, there are all the conditions favourable for the development of a vesical hernia. Relaxation of the abdominal wall is a factor also favouring the condition, and the bladder may be found in post-operative herniae. Congenital predisposition is a rare cause of this type of hernia, as most of the patients are elderly before the hernia is found. A prevesical lipoma is regarded as an important factor; this mass of fat is adherent to the anterior portion of the bladder, and by the traction of the lipoma the bladder is drawn through the hernial orifice. A cystocele may also result from traction of a pre-existing hernia; this may be spontaneous or follow pull from adhesions. Femoral hernia of the bladder occurs almost always in women; inguinal hernia may be found in men. The most important cause in women is pregnancy.

581. Carcinoma of the Spine.

CARCINOMA of the bodies of the vertebrae is not a very unusual condition. The vertebrae are probably, amongst the bones, the most favoured sites for the location of metastases. OPPENHEIMER (*Journal of Bone and Joint Surgery*, April, 1922) reports 32 cases of cancer of the spine. The primary lesion was found in the breast in 18 cases, and this appears to be the commonest primary focus; in 12 cases the metastatic symptoms appeared before the primary site was determined. In some cases a neuter angular kyphosis may be the first symptom, and in the absence of a primary focus it may be impossible to differentiate this condition from Pott's disease. Symptoms of root invasion, in the absence of bony changes due to tuberculosis, are, for the most part, characteristic of carcinoma; vague back pains, ill-defined pain on pressure over the spine, and a negative x-ray report may readily tempt one to consider the condition functional. The symptoms of actual invasion of the spine or spinal roots are striking, the continuous agony being found in no other pathological process. Continuous bilateral sciatica often leads to the discovery of an unsuspected carcinoma. Changes in the contour of the spine in connexion with other symptoms are very suggestive. In some cases the primary carcinoma in the prostate, thyroid, or lungs, had not been demonstrated until they came to autopsy. A radio-

graph may not clear up the diagnosis in early cases, and the early diagnosis of cancer must be tentative in many instances. The peculiar character of the segmental pain or the early changes in the conformation of the spine will often aid in securing a diagnosis. Cases presenting metastatic bone and cord symptoms gave an average duration of fourteen months.

OBSTETRICS AND GYNAECOLOGY.

582. Cystic Tumours of the Uterus.

ACCORDING to MACCABRINI (*Annali di Ostetricia e Ginecologia*, March 31st, 1922), serous cysts of the uterus, which are usually multiple, small, and superficial, are rare and have little clinical significance. Blood cysts due to trauma are rare; lymphatic cysts have occasionally been described. Mucous or retention cysts may be situated in the mucous or submucous layers, constituting in the cervix Naboth's cysts; or more deeply in the myometrium, usually as an accompaniment of endometritis: in the latter situation they occur most commonly in the fundal and especially the isthmic region. Dermoid and hydatid cysts are occasionally found. True uterine cysts, having a fibro-muscular wall and a lining of cylindrical or cubical epithelium, arise from dilatation of the Wolffian ducts or proliferation of their vestigial remnants; occasionally they are due to abnormalities of development of the Müllerian ducts. Cysts in connexion with adenomyoma, when situated towards the exterior of the uterine wall, probably arise in Wolffian remnants; otherwise adenomyomatous cysts are an accompaniment of chronic (not infrequently tuberculous) endometritis and metritis. Clinically these cysts cause excessive haemorrhage, pelvic pain undergoing periodic exacerbations, and irregular uterine enlargement: carcinomatous metaplasia is rare. Cysts accompanying uterine fibromyoma are not very rare, being found in about 3.5 per cent. of cases: Maccabruni records nine personal cases, and divides cystic fibromyomata into two groups, according as an epithelial lining is present or absent. Cysts having a cellular lining arise in dilatation of lymphatics, or more commonly in included embryonic remnants or post-follicular epithelial penetrations which for a time are latent. Formation of cysts, devoid of epithelial lining, in fibromyomata (the so-called pseudocysts) is due to disordered local nutrition; factors which may be concerned are oedema, endarteritis, congestion, haemorrhage, and gangrene. Cystic fibromyomata may attain great size, weighing up to 50 kilograms and containing as much as 15 litres of fluid; they may be submucous or interstitial, but are most commonly subserous. Clinically cystic transformation of a myoma is characterized by irregularity of haemorrhage, which sometimes becomes increased; by increased rapidity of growth of the tumour, sudden acceleration not infrequently giving rise to acute peritoneal symptoms and signs; and sometimes by symptoms of compression of adjoining viscera. The tumour may be regular or irregular, and is not necessarily fluctuant; diagnosis from ovarian cyst or pregnancy may present considerable difficulty. Coincident ascites is not rarely found. Among the complications which may ensue are rupture into the uterus or the peritoneal cavity, torsion, suppuration, and sarcomatous degeneration. Large cysts may also occur in sarcoma and fibrosarcoma. Maccabruni gives 515 references to the literature.

583. The Rate of Growth of Cervical Cancer.

WOLFF (*Zentralbl. f. Gynäk.*, May 13th, 1922) discusses the influence of pregnancy on the malignancy of cervical cancer. Some authors have claimed that cases of cervical cancer take a less favourable course in the pregnant than the non-pregnant uterus, partly because of increased local vascularity and partly because the patients concerned are comparatively young. Theilhaber and others, on the contrary, believe that during pregnancy cervical cancer shows itself less than usually malignant: spread of cancer, which is favoured in anaemic (scar, senile, or arterio-sclerotic) tissue is inhibited by the hyperaemia accompanying pregnancy. During the last ten years the records of the Breslau State Hospital show that 10 per cent. of cases of cervical cancer in women aged from 25 to 40 occurred during or within a year after pregnancy. From analysis of these cases the writer is inclined to believe that there is little evidence that gestation influences in one direction or the other the course of cervical cancer. The variations shown in the course of individual cases are to be ascribed to the different degrees of malignancy shown by different tumours. In criticism of those statistical comparisons which seemed to show a less rapid course in uterine cancer in connexion with pregnancy it must be remembered that about this time early cases are more likely to be detected accidentally during routine examinations. FORST (*Ibid.*) points out that it is difficult to ascertain with

accuracy how long the morbid process has existed in cases of cervical cancer. The accuracy of the evidence obtained by questioning patients as to the date of onset of the early symptoms (specified as chronic discharge, especially of a blood-stained, watery nature, and bleedings during the menopause, after douching or after coitus) is doubtless; moreover, these signs are not invariably present. Schottländer and Kermann express the opinion that large infiltrating or proliferating growths have usually existed for from two to six months. Forst relates the case of an 8-para, aged 49, who for five months had suffered from haemorrhage, commencing two years after the menopause; temporary improvement followed curetting, but return of the symptoms led to canterization of a cervical erosion, of which an excised fragment showed no microscopic characters suspicious of malignancy. Thirty-five days later findings on examination were normal, but at the end of a further period of thirty-one days the patient returned presenting the symptoms and signs of an advanced cervical cancer. The growth, which was as large as the fist, had extended on one side into the vagina and parametrium.

584. Aortic Disease in Pregnancy.

ACCORDING TO FELETI (*Rivista d'Ostetricia e Ginecologia Pratica*, April, 1922), pregnancy appears to be considerably less frequently encountered among the subjects of aortic than of mitral disease. According to various observers, aortic disease is met in from 0.1 to 0.2 per cent. only of pregnancies, and De Sio-Cesari in a study of 507 cases of pregnancy complicated by cardiopathy found 3.9 per cent. of aortic lesions, in comparison with 8.08 of mitral disease. It is possibly due to a greater average duration of compensation in aortic than in mitral disease that pregnancy in the former less frequently leads to medical treatment. Many writers affirm that aortic disease does not gravely influence foetal or maternal mortality in connexion with pregnancy. Feleti's experience does not accord with this. The six cases of pregnancy and aortic disease which he describes led to the issue of five premature foetuses, of which four were dead, and one a living healthy child; two of the mothers died shortly after labour, and three exhibited grave metrorrhagia during gestation.

PATHOLOGY.

585. The Infectious Nature of Disseminated Sclerosis.

THE conception of the infectious nature of disseminated sclerosis, first put forward by Marie, seems likely to prove correct. In addition to evidence previously adduced in its favour, PETTIT (*C. R. Soc. Biologie*, April 29th, 1922) now records some very convincing facts which lead him to conclude that the origin of the disease is due to the activity of a spirochaetal organism which is found in the cerebro-spinal fluid of patients during life. Four cases of the disease were studied, and from the spinal fluid of each it was possible to infect either monkeys, guinea-pigs, or rabbits, and to demonstrate the presence of the spirochaete in the cerebro-spinal fluid after some days. In the case of the first patient the cerebro-spinal fluid was withdrawn and injected intrathecally into a monkey. After presenting motor disturbances and paralytic disorders of the posterior limbs the animal died in twelve days. The blood, the cerebro-spinal fluid, and the spinal cord all proved infective to rabbits, on which five successful passages were performed. The spinal fluid of the same patient was also injected into several rabbits and guinea-pigs; some of the former animals died, while all the guinea-pigs survived, but without exception they were all shown to contain the peculiar spirochaete in the cerebro-spinal fluid during life. The same results occurred in the other three patients from whom rabbits were infected. Until a greater amount of knowledge has been gathered in respect to the general properties of the organism, the author considers any attempt at nomenclature to be somewhat premature.

586. Renal Glycosuria.

LEWIS (*Arch. Intern. Med.*, April, 1922) reports three cases of renal glycosuria, the cardinal points in the diagnosis of which are (1) glycosuria without hyperglycaemia; (2) little, if any, relationship between the carbohydrate intake and the amount of glucose excreted in the urine; (3) the absence of the signs and symptoms characteristic of diabetes mellitus; and (4) a long period of observation during which the patient shows no tendency to develop diabetes mellitus. The first case was of unknown or idiopathic origin and has been observed over a period of six years; the blood sugar and blood-sugar curve have always been normal, but the patient has marked glycosuria without symptoms and is apparently in excellent health.

The second case developed glycosuria following chronic diffuse nephritis, and the glycosuria has been constant but never above 16 grams, and is largely independent of the carbohydrate intake. Synchronous sugar determinations on blood and urine show the presence of a glycosuria with 0.068 per cent. sugar in the blood, and the response to 100 grams of glucose falls within the limits of a non-diabetic case of nephritis. There are no other signs of diabetes mellitus. The third case was first seen on account of scurvy, and was found to have an arterio-sclerotic kidney. This patient is aged 74 and passes from 30 to 50 grams of glucose each day, but the ordinary changes of diet had very little effect on the amount of sugar excreted. The urine showed 2.7 per cent. sugar with only 0.064 per cent. in the blood, and there are no other signs of diabetes. The response following the ingestion of 100 grams of glucose showed a remarkably high and prolonged rise in the blood sugar, which is probably a retention phenomenon, or may be connected with the high diastatic activity so often seen in severe nephritis.

587. Bacterial Virulence in Relation to Vaccine Production.

How far is the efficacy of a vaccine used for prophylactic purposes dependent on the virulence of the strain of organism employed in its preparation? Such is the question which HARVEY and IYENGAR (*Indian Journ. Med. Research*, April, 1922) endeavour to answer, in having recourse to argument by analogy from animal experimentation. First of all they show that the virulence of *B. aviscipitius*—an organism of the Pasteurella group—can be maintained at approximately the same level for at least a year by weekly subculture on blood agar, while the same strain cultivated in the same way on ordinary agar falls in virulence to a very low point. Having now one virulent and one avirulent strain, they proceed to test their relative immunizing properties on pigeons, using as a test their ability to protect against a lethal dose of living organisms injected intravenously. The results, carefully guarded by control experiments on uninoculated birds, show that the degree of protection afforded by either strain is for all practical purposes identical. Whether it is justifiable to conclude from these experiments that the antigenic and the invasive properties of bacteria are two quite separate and distinct functions of their activity is a question which they do not attempt to solve, but that this may be the case is shown—or at least strongly suggested—by the experience gained in the use of typhoid vaccine. In this country the particular strain of organism employed in the manufacture of the army vaccine is one which was isolated more than twenty years ago, and though its virulence for animals is of a comparatively low order it still appears to retain its immunizing properties for the human being unchanged.

588. Basic Metabolism in Exophthalmic Goitre.

RESEARCHES carried out by LEBBE and STEVENSON (*C. R. Soc. Biologie*, May 13th, 1922) on patients suffering from Graves's disease, with a view to determining the changes which occur in the basal metabolism, are directly confirmatory of the numerous results obtained recently by American workers. The number of calories given out per square metre of surface per hour in the normal individual varies from 35 to 40. In mild cases of hyperthyroidism this figure is increased to an average of 51, while in fully developed cases of Graves's disease it rises to a mean of 66. In patients displaying a condition of simple goitre the basal metabolism is unaltered, except occasionally in recent cases, when a slight rise may be met with. The estimation of the basal metabolism is of considerable value, not only from a diagnostic point of view, but also from that of prognosis. In the same journal the authors record their findings with regard to the hyperglycaemia induced in patients suffering from Graves's disease by the administration of 45 grams of glucose. The titre of the blood sugar was estimated every half-hour for the following five or six hours. Both in the mild and in the advanced cases the increase over the normal content as determined by controls is distinctly marked. The reaction appears to be very constant, and is therefore of value for assisting in the diagnosis of doubtful cases of the disease.

589. A Simple Method for the Detection of the Tubercle Bacilli.

PANE (*Rif. Med.*, April 3rd, 1922) recommends the following method in cases where it is difficult to find tubercle bacilli: The suspected sputum is placed in a sterile glass, and four times as much sterile physiological solution added and the mixture left in an incubator for twenty-hours at 37° C. The mucus and cells become liquefied, and after centrifugalization and elimination of the liquid rich in organic matter the bacilli stained by the Ziehl-Neelsen method are much more readily seen.

Observations

ON

THE DUODENAL TUBE IN THE DIAGNOSIS AND TREATMENT OF BILIARY DISEASES.

BY

JONATHAN MEAKINS, M.D., F.R.C.P.E.,

CHRISTIAN PROFESSOR OF THERAPEUTICS, EDINBURGH UNIVERSITY;
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

(From the Department of Therapeutics, University of Edinburgh.)

IN 1917 Meltzer¹ reaffirmed his "law of contrary innervation" and his conviction that disturbance of this law was of great pathological significance. He demonstrated it particularly in regard to the physiological function of the gall bladder in promoting an interrupted flow of bile into the intestine. He further suggested instances where suspension of the physiological process might give rise to pathological sequelae. He drew attention to the musculature of the gall bladder, which on contraction empties this viscus of its fluid contents. The antagonist of this musculature is the circular muscle of Oddi, which is situated at the termination of the common bile duct, thus closing the papilla of Vater at its duodenal entrance. In conformity with the "law of contrary innervation" the muscle of the gall bladder is relaxed and the muscle of Oddi contracted during the storing of bile, while a reverse action takes place when the bile is being poured into the duodenum. The nervous control appears to be equally interesting.

"According to Doyon, stimulation of the peripheral end of the splanchnic nerves causes simultaneously a contraction of the gall bladder and an inhibition of the tonus of Oddi's muscle. The vagus, on the other hand, seems to contain motor fibres for the sphincter of the common duct and inhibitory nerve fibres for the gall bladder. Furthermore, also the afferent unmyelinated show the character of contrary innervation. For instance, stimulation of the central end of the vagus causes simultaneously a contraction of the gall bladder and an inhibition of the sphincter muscle."

There are numerous suggestions in physiological experiments that variations in dietary may influence this co-ordination of gall bladder and sphincter muscular action. Sometimes this influence may be for good and sometimes for evil. Most first demonstrated the fact that the injection of peptone or albumoses into the duodenum was followed by the prompt discharge of bile into it, and that this was due to a reflex act which caused the simultaneous relaxation of the sphincter of Oddi and the contraction of the gall bladder.

In a footnote to his communication Meltzer records his observation that the application of a 25 per cent. solution of magnesium sulphate "to the mucosa produces a completely local relaxation of the intestinal wall." Such a result is not obtained if the salt passes through the stomach. He therefore makes the suggestion that the local application of a 25 per cent. solution of magnesium sulphate by means of the duodenal tube might relax the sphincter of the common duct and permit the ejection of bile and perhaps even the removal of a calculus of moderate size wedged in the duct in front of the papilla of Vater.

The development of the use of the duodenal tube by Eihorn and other workers stimulated investigation, and many observations were made upon the normal and pathological contents of the duodenum. In particular these observations were directed to the character and digestive power of the pancreatic and hepatic secretions. Attempts to increase the flow of these fluids, except by means of the so-called cholagogues administered by mouth, were not undertaken until Lyon² applied the observations of Meltzer in regard to the local duodenal action of magnesium sulphate on the gall bladder and bile-duct sphincter. Lyon's experiments were entirely successful and established the basis for extended investigation into the contents of the gall bladder in health and disease. He further developed the technique in order that the gall bladder might be evacuated of its fluid contents whenever considered advisable if such evacuation were mechanically possible.

Methods.

The patient should fast for at least six hours before the duodenal tube is introduced. The tube is then passed to the first mark (40 cm.). The stomach contents are then aspirated by means of a glass syringe. If the stomach be normal, they will be found to consist of slightly opaque acid fluid with

flakes of mucus; this is quite typical of the resting gastric juice. It is well to examine this material, when obtained, as to its total acidity, for frequently useful information may thus be obtained. The stomach is then washed out with 30 c.cm. of tepid water, which is introduced by syringe and withdrawn. This repeated process need not be prolonged if the stomach appears normal. The patient is now placed on the right side in the recumbent position. The duodenal tube is then passed to the second mark (55 cm.) and the process of washing and evacuation repeated two or three times. The tube is finally introduced to the third mark (80 cm.), where it is allowed to remain. The patient is kept lying on the right side with the abdomen inclining towards the bed, although it is not found advisable that he should lie too flat on the abdomen. It is important that the patient should be made as comfortable as possible in order that restlessness and fatigue may be avoided. The patient remains in this position for about half an hour, when a small sample of the contents of the gut is removed for examination. If the end of the tube be in the duodenum the fluid withdrawn may be scanty, alkaline or neutral, and sometimes more or less bile-stained. If it contain free hydrochloric acid (indicated with Congo red paper) it may be presumed that it has not yet passed the pylorus or at the best is just within the duodenum. Each fifteen minutes following a small sample of the contents is obtained for examination. When these samples are alkaline or neutral and probably slightly bile-stained it may be concluded that the end of the tube is well into the duodenum. This usually takes from three-quarters of an hour to an hour, but sometimes longer. In a certain number of cases it may be impossible to obtain an alkaline or neutral sample. If the resting gastric juice has been examined a high degree of acidity may frequently have been found in such cases. If the final samples remain acid but with a much lower concentration of titratable acid than that of the resting gastric juice it may be presumed after two hours that the tube has reached the duodenum, especially if the fluid be bile-stained. Subsequent events will indicate whether this be so or not.

When it has been decided that the tube is in the duodenum 30 c.cm. of a 25 to 50 per cent. solution of magnesium sulphate is injected through it. This is allowed to remain for five or ten minutes, when a sample may be removed. If the procedure has been successful the fluid will be found to be deeply bile-stained, and if the withdrawal be continued at intervals almost pure bile may be obtained. If diagnosis be the principal point in view the bile may be withdrawn in fractional amounts and placed in numbered test tubes and subsequently examined when the procedure has been completed. If, however, drainage or thorough evacuation of the gall bladder be the primary object, then persistent withdrawal of the bile is not required and the contents (magnesium sulphate and bile) of the duodenum may be allowed to pass down the bowel. In these circumstances care must be taken not to introduce too much magnesium sulphate, as violent purging may then result.

In the practice of a busy practitioner, where a nurse skilled in the procedure is not available, or in the wards of a hospital where a number of patients are treated each day by this method, the steps outlined above may be too time-consuming. The following plan may therefore be adopted. The tube is passed the night before to the 80 cm. mark, a spring clip being attached to the free end in order to prevent leakage, and pinned to the nightdress. The patient is then instructed to sleep on the right side. If there be restlessness and difficulty in sleeping, 1 gram of sodium or potassium bromide, or an equivalent amount of some mild hypnotic in solution, may be introduced into the stomach through the tube, which may be completely emptied by injecting a few cubic centimetres of air. A good night's rest is thus usually obtained. At a convenient hour in the morning a small sample of fluid is withdrawn. Only exceptionally does this fail to give positive evidence of coming from the duodenum. The magnesium sulphate may then be introduced. When it has been determined that the bile is flowing freely the tube may be removed, and after half an hour the patient may have the breakfast indicated under the circumstances of the condition irrespective of the duodenal tube having been introduced.

* The passage of the tube into the duodenum may be hastened by having the patient drink about 150 c.cm. of hot clear meat soup or milk. This does not obscure the future colour taken before the tube is introduced to second washing and evacuation of the

† Under conditions of the biliary tract to lavage the duodenum with a bland aseptic solution before the removal

The importance of this direct method of investigating the character and flow of bile can hardly be overestimated in pathological conditions of the liver, the gall bladder, and their ducts.

Abnormalities of the Bile.

Lyon⁵ has drawn attention to the difference in the character of the bile during consecutive periods of the physiological drainage of the bile ducts and gall bladder. The first bile which appears is of a light golden colour and is quite transparent. This is followed by a much larger quantity of darker greenish-yellow bile, which is more concentrated and frequently quite viscid. Finally a small quantity of much paler and thinner bile is obtained. Lyon considers that these three types of bile are at the time of drainage in three more or less separate portions of the biliary tract. The bile in the common duct, and probably the cystic duct (10 to 20 c.cm.), is the first bile to appear. There is then a short transition flow of bile, which rapidly becomes darker until the darker bile is obtained. (This may amount to between 30 and 150 c.cm.) Finally a small amount of light yellow bile is obtained, which flows slowly and steadily. It has been suggested that this bile is identical with that which flows normally from the liver and is stored in the gall bladder, where it becomes concentrated during the periods of physiological biliary stasis. It must always be remembered that normally the bile does not enter the duodenum in a continuous stream but intermittently when the appropriate stimulus is in operation. This stimulus is normally the product of gastric digestion—the acid chyme with proteoses, albumoses, and peptones. As will be mentioned later the character and periodicity of diet may have an important bearing on biliary affections.

A careful macroscopical, microscopical, and, if indicated, chemical examination of the different succeeding and continuous aspirations of bile may give much valuable information as to the site and character of the pathological process. It has been found to be extremely difficult definitely to diagnose abnormal conditions of the lower biliary passages (independent of the gall bladder) by an examination of the first samples of bile obtained. If they are found to be abnormal it cannot be definitely stated that this bile has not been contaminated by the residue from the last expulsion from the gall bladder which may be the site of the pathological condition. This difficulty, however, does not arise if the first portion of the bile be healthy and the second portion (dark green and more viscid) be definitely abnormal, whilst the final portion is again found to be normal. Under such conditions it may be definitely affirmed that the pathological lesion is situated in the gall bladder. Furthermore, if the whole of the bile—even the last portions—be abnormal, it may be inferred that the abnormal process has either arisen in the hepatic duct or above, or that it has extended upwards into these channels. In such cases this may be taken as definite evidence of an extensive cholangitis, and even hepatitis may sometimes be diagnosed. If the first portion only of the bile be abnormal it may be assumed that the lesion is confined to the common duct.

The various indications of abnormal conditions in the biliary passages as indicated by the bile are as follows: increased viscosity and turbidity, presence of flakes of bile, retained mucus, pus cells, large numbers of degenerated epithelial cells and pathological micro-organisms, such as *Streptococci*, *B. typhosus*, large numbers of *B. coli*.⁶ Small gritty particles of material which may chemically be identified as biliary sand, and even definite gall stones of considerable size, have been obtained. The diagnosis of the local lesion will depend upon the degree and character of the abnormality of the bile. If there be numerous pus cells, with or without numerous micro-organisms, it may be safely inferred that the condition is of an active inflammatory character. This is usually associated with a systematic reaction. A chronic suppurative lesion of the gall bladder may, however, exist without pronounced systematic or local symptoms provided a moderate degree of biliary drainage be present. Such a degree of drainage, however, may not be sufficient to prevent the development of chronic symptoms of intoxication.

Abnormalities of Biliary Drainage.

Evidence of partial or complete mechanical obstruction due to gall stones, adhesions, neoplasm, and other conditions is frequently found. The causes of pathological stasis or partial

⁶ A small number of these organisms are frequently found in the bile, and may probably be due to the filtration action of the liver on the portal blood.

retention are of great importance in the production of immediate symptoms or future complications. But there are other less obvious conditions which are of even greater importance. Meltzer⁷ has quite clearly pointed out the pathological sequence of events which may follow upon prolonged biliary stasis. It is recognized that this may occur as a secondary condition consequent upon the impaction of gall stones, inflammatory swelling of the tissues, new growth, or pressure from without the passages. But his claim that primary biliary stasis may in itself lead to certain of these more conspicuous lesions is not commonly appreciated.

It has been demonstrated that the bile in health may contain pathological organisms. That these do not set up pathological processes is due to the fact that the cells of the biliary passages are of normal vitality. In such soil micro-organisms seldom find a favourable habitat for their growth and invasion. If, however, abnormal conditions arise which lower the vitality of the parts, or in any manner improve the habitat of the organisms for their growth, then pathological processes are apt to arise.

As has been stated previously, the evacuation of the gall bladder is an intermittent act depending upon initiation of a definite reflex by suitable stimuli. In order that this physiological function may operate properly two things are necessary—first, a properly balanced nervous path for such a reflex, and secondly, a proper stimulus. This physiological reflex is under the control of the vagi and the splanchnic nerves, and the evidence seems to indicate that the vagus contains motor fibres for the sphincter of the common duct and inhibitory fibres of the gall bladder. Thus it is quite conceivable, and indeed probable, that central impulses are capable of inhibiting or at least rendering more difficult the action of the proper stimulus even if it be normally operative. The emotional and other states which are conducive to the disturbance of many physiological reflexes need not be discussed at present.

The various stimuli which may initiate this reflex are not as yet fully understood, but that they are intimately connected with the processes of normal digestion there is good reason to believe. Bruno has shown that during the fasting stage no bile enters the duodenum, but when the digestive chyme enters the stomach after a meal bile is ejected into the duodenum. Rost has shown that if the gall bladder be absent the bile enters the duodenum in a continuous stream. He has further demonstrated in a healthy dog with the gall bladder in operation that injection of albumoses, peptones, and other products of protein digestion into the duodenum immediately initiates a flow of bile from the papilla of Vater. He has proved that this flow of bile is produced by the reflex act of simultaneous contraction of the gall bladder and relaxation of the sphincter of Oddi. These observations would indicate that the gastric contents furnish the normal stimulus for this reflex. This, however, is not entirely true. Oddi¹⁰ and Archibald¹¹ have conclusively demonstrated that high acidity of the duodenal contents stimulates the contraction of the sphincter of Oddi. The resistance which this spasm of the sphincter muscle affords to the flow of bile may be judged from experiments. Archibald found that under fasting conditions 180 to 330 mm. pressure of water forced fluid through the sphincter, but when the duodenal mucous membrane was drenched with 15 per cent. solution of hydrochloric acid it took 330 to 800 mm. pressure of water to produce the same result.

We are therefore faced with certain facts which may indicate how a deleterious action upon the normal physiological flow of bile may be brought about—how, in other words, a biliary stasis may be produced. The question naturally arises, Is such a biliary stasis a harmful condition? As yet sufficient evidence has not been accumulated to answer this question in full, but there is much to indicate that it is a condition which may be fraught with much eventual mischief. It has already been mentioned that normal bile may contain pathological organisms. Much more so is this the case in infectious diseases such as typhoid fever. In ordinary circumstances biliary infections are not common occurrences, probably for the reason that the mucous membranes of the passages are healthy and the flow of bile quite normal. But it is well to recognize the evil influences which biliary stasis has in predisposing to biliary disease. Whether this be by lowering the resistance of the containing structures, or in providing a suitable habitat for the growth of pathological micro-organisms, or in both ways, is not as yet clear.

In addition to the pathological processes which may be produced in the biliary system by a disturbance of the reflex

ejection of bile we have to consider the very important pathological condition which may be initiated in the pancreas. The observation of Opie⁵ that the impaction of a small stone in the ampulla of Vater could give rise to acute haemorrhagic pancreatic necrosis has been repeatedly confirmed. Opie demonstrated that this most serious lesion was consequential upon the regurgitation of bile into the pancreas through the duct of Wirsung. Archibald⁴ has pursued this subject farther, and has shown that such regurgitation of fluid can be accomplished by producing a spasm of the sphincter of Oddi and increasing the intrabiliary pressure. Further, he has demonstrated that acute haemorrhagic necrosis of the pancreas may be produced in this manner.⁶ Whether the pancreatic lesion be acute or chronic depends upon a number of circumstances. But the fact seems now quite evident that biliary stasis is frequently a most important factor in producing these lesions.

Functional Biliary Stasis.

It is not the purpose of this communication to discuss biliary stasis caused by gross mechanical lesions, but to deal chiefly with biliary stasis of a so-called functional character—a stasis which is present before structural changes of an obstructive type are evident. Meltzer has pointed out the possibility that by some strong mental excitement

“tonic contraction of the sphincter of the common duct, not in period assigned for the discharge, does not become relaxed while the gall bladder contracts within the usual normal limits; thus would result in abnormal stasis within the biliary ducts which may lead to icterus—emotional icterus. Or both the muscle fibres of the gall bladder and of the sphincter are abnormally strongly contracted, which would lead to biliary colic with consecutive jaundice without the presence of catarrhal conditions or of calculi, at least not in the first few attacks of comparatively short duration.”

In addition to the possible action of powerful emotion in producing a functional biliary stasis there must be considered the probable results of a deficiency of the proper stimulus. It has been pointed out that the products of normal gastric protein digestion play a prominent part in supplying such stimulation.⁷ This being the case, it will be readily appreciated how important it may be that a properly balanced diet should contain a certain amount of protein. Meltzer has particularly emphasized the possible dangers in this regard of a purely vegetarian diet. A diet may contain sufficient calories but may not be properly balanced in so far as diet may affect the physiology of digestion and metabolism.

The manner in which the contents of the stomach, apart from the products of digestion, influence the biliary function has already been suggested. If the duodenal contents be kept abnormally acid, the physiological relaxation of Oddi's sphincter will not take place. Thus it will be seen that gastric hyperacidity may possibly exercise an important influence in producing a certain degree of functional biliary stasis.

The association of gastric hyperacidity with biliary lesions in general assumes an additional importance when considered from this point of view. It has been recognized for some time that lesions of the gall bladder are frequently accompanied by signs and symptoms of gastric hyperacidity. It has even been held by some that the hyperacidity has been reflexly produced by the cholelithiasis. Little or no evidence has been advanced in support of this view except the observation that the two conditions are frequently associated. In view of the present experimental observations it would be more consonant with the facts to suggest that biliary stasis and subsequent gall-stone formation might be the result rather than the cause of hyperacidity.

The influence of functional biliary stasis upon the formation of gall stones is probably very important. Two outstanding factors in the production of gall stones are recognized—bacterial invasion and biliary stasis. In regard to the etiology of gall stones, Mayo-Robson⁷ makes the following statement:

“Anything, therefore, which causes stagoation of bile may dispose to gall stones; on the other hand, whatever leads to a regular emptying of the bile passages will tend to clear out such detritus as cast-off cells and incipient collections of cholesterol crystals and mucus, and thus to prevent the formation of gall stones. Among the remoter causes we must consider age, sex, habits, dress, diet, diathetic conditions, and disease.”

In regard to the diet he makes the following interesting observations:

“If the supply of nitrogen in the food be limited, the bile salts will be diminished and cholesterol may be precipitated. This may serve to explain the presence of gall stones in gouty persons who on account of the lithic diathesis limit their intake of nitrogen. The larger consumption of farinaceous food in Germany may also serve to explain the greater prevalence of gall stones there than in England, where meat enters more extensively into the dietary. In diabetes, in which nitrogenous food is prescribed, gall stones are rarely found.”

Since Gallippe⁸ in 1886 first demonstrated the presence of bacteria in biliary calculi much attention has been paid to this aspect of the question. The evidence collected goes far to substantiate the view that bacterial infection of the bile passages is the chief cause of the origin of gall stones. As has been pointed out above, the normal bile frequently contains pathological micro-organisms. The numerous routes which have been suggested whereby they may reach the bile need not be discussed in detail. It will be sufficient to mention the two main ones—namely, an ascending infection by way of the bile ducts and infection through the liver from the portal or systemic blood stream. In such circumstances it is not surprising that cholelithiasis is a common condition. In fact it might be expected to be much more frequent than it is. It has already been stated that the two most important factors in preventing the pathological growth of micro-organisms in biliary passages are a healthy mucous membrane and efficient biliary drainage, while biliary stasis in itself may lead to a lowering of the resistance of the biliary mucous membrane. One attack of biliary infection is frequently followed by others. It is quite readily seen how this may be the case when it is realized that biliary inflammation leads to a prolonged partial stasis and the stasis perpetuates the favourable habitat for the growth of micro-organisms. In this manner a vicious circle is established.

It is quite evident from these observations and experimental facts that biliary stasis and any abnormal conditions which tend to promote it or to perpetuate it are probably the most important factors in the etiology of the more common biliary lesions. The initial form of stasis in all these circumstances is most probably of a functional nature resulting either from a spasm of the gall-duct sphincter or prolonged absence of the proper stimulus in sufficient strength.

Treatment of Biliary Lesions.

Apart from its value as a diagnostic measure, the use of the duodenal tube as outlined lends itself to treatment. In conditions where there is biliary stasis independent of complete obstruction it is advisable to promote free and periodical emptying of the gall bladder and passages. This is of particular importance when the stasis is associated with some chronic inflammatory process. If cholelithiasis be present, and there be good reason to avoid an operation if possible, much in the way of amelioration may be expected. This hope is especially warranted when it is realized that in practically every case of cholelithiasis a chronic infection of the biliary passages is present, which infection perpetuates and is perpetuated by biliary stasis in the manner of a vicious circle. The claims of operation *versus* duodenal tube drainage need not be considered. The indications for either therapeutic measure are quite clearly to be distinguished. It may be observed, however, that in the use of the duodenal tube no physiological organization is disturbed in so far as present knowledge goes. In the case of operation this cannot be conceded. After cholecystectomy the rhythmic flow of bile ceases and it dribbles into the duodenum whether necessary or not. This may be harmless, but at any rate is not physiological, and it is possible that the presence of large quantities of bile in the intestines when it is not needed may exert some deleterious influence. Furthermore, it is established that the bile is more concentrated in the gall bladder than in the hepatic ducts, and that bile salts are absorbed from the intestine to be stored again in the gall bladder, so that an ejection of concentrated bile may take place when necessary. Without the gall bladder none of these physiological processes may be carried out. In the case of cholecystectomy not only is the gall bladder physiologically eliminated but an open door for infection from the bowel into all the radicles of the biliary system is permanently established. However, in spite of all these objections, and apart from the risk attending any major operation, it is sometimes imperatively indicated and therefore must be undertaken. But there are many instances in which operation is not

* It is probable that there are other physiological stimulants which as yet have not been demonstrated.

indicated, in fact the risk of the cure may be greater than that of the disease; in addition there are conditions where operation as a therapeutic measure would be useless.

Catarrhal Jaundice.

The prolonged course of catarrhal jaundice is well known, and anything which would shorten it would be welcomed. It is frequently associated with systemic infections or obvious infections of the digestive tract from the teeth to the duodenum. In fact, catarrhal jaundice is a result of an infection of a greater or lesser part of the biliary passages. Therefore there are present in this condition the two fundamental factors, stasis and infection, most liable to promote biliary mischief. The longer the stasis remains in whole or in part the greater will be the liability to future trouble. The indication, therefore, is to re-establish efficient biliary drainage as soon as possible. Lyon² in a series of cases of catarrhal jaundice occurring during an influenza epidemic in the United States navy reduced the average duration of the jaundice by 50 per cent. In those cases treated by the expectant measures the average duration was thirty-five days, while in those cases treated with the duodenal tube the duration was seventeen days.

Cholecystitis and Cholangitis.

The probable vicious circle established by biliary stasis and cholecystitis has already been referred to. The treatment of severe suppurative or gangrenous cholecystitis by operation is well recognized, but there are many degrees of lesser severity in which the use of the duodenal tube is especially indicated. The complete evacuation of the gall bladder at frequent intervals (twenty-four hours) promotes freer drainage and conduces to the more rapid resolution of the morbid condition. It also helps to remove small collections of pus, cholesterol, precipitated bile salts, mucus, and bacteria which are so prone to form the nucleus of a gall stone. The chances of the infection spreading to distant radicles of the biliary tract and into the pancreas are also diminished. Even where surgical drainage of the gall bladder has been instituted it may be demonstrated by the duodenal tube that the infection is persistent, and that much can be done to hasten resolution by duodenal drainage.

Cholelithiasis.

Instances have been reported where small faceted gall stones have been evacuated with the bile on the use of the duodenal tube, but it must be acknowledged that such instances are rare. It is not at all uncommon, however, to find biliary sand, which represents the early stages of the formation of gall stones, in the evacuated bile even where the presence of larger gall stones is not diagnosed nor definitely considered.

There is no reason to believe that through duodenal drainage the ejection of gall stones from the gall bladder can be brought about. Where small stones have been found it may be surmised that they had been lodged in the ampulla of Vater. In so far as cholelithiasis is concerned there is as yet no evidence to indicate that duodenal drainage can replace operative procedure. There is, however, much to recommend the employment of both measures.

Numerous cases of cholelithiasis are met with where an operation would be attended by considerable risk or might be absolutely contraindicated. In these circumstances much relief may be obtained by the use of the duodenal tube. In fact it may be demonstrated that many attacks of so-called gall stones are in reality periods of acute exacerbations of cholecystitis and cholangitis plus cholelithiasis. In such cases the periodic use of the duodenal tube may in great part clear up the chronic infection and thus obviate the recurrent attacks of cholecystitis.

The following reports may serve to demonstrate the value of this plan of duodenal drainage of the biliary tract:

CASE I.

J. M., female, aged 30; married, no children. Duration of illness four years. The onset was gradual with pain in the right side of the epigastrium radiating to the right shoulder. The first attack lasted for some hours and was associated with vomiting. Similar attacks occurred during the next three weeks. She was then free of attacks for three and a half years. Eight weeks before coming under observation the attacks of pain with gradual onset recurred, each attack lasting about six hours and occurring every two or three days. Otherwise the patient was free of symptoms. On examination, there was acute tenderness and rigidity over the gall bladder, very slight jaundice and glycosuria with minute traces of bile in the urine. The stools were not clay-coloured.

Treatment with the duodenal tube showed the bile to be viscid, turbid, and of a dark greenish colour. On examination many epithelial cells and leucocytes but no micro-organisms were found. Repeated biliary draining relieved all the symptoms, the bile became quite clear and of light greenish colour, and the glycosuria disappeared.

This appeared to be a case of recurring cholecystitis with biliary stasis and associated glycosuria. It was thought probable that the glycosuria could be accounted for by the secondary pancreatitis resulting from chronic biliary stasis. A year elapsed without return of symptoms. The glycosuria did not return although the patient was on a full diet and had a high carbohydrate tolerance.

CASE II.

C., female, aged 64; married, twenty-one pregnancies. During the last ten years the patient had suffered from periodical attacks of "indigestion and gastric discomfort," which were relieved by vomiting. The pain was never extremely severe, came on gradually, and usually lasted for some days, being felt in the upper right quadrant of the abdomen and radiating to the right shoulder-blade and shoulder. It lasted from seven to ten days and was usually associated with jaundice. There was no history of acute paroxysms of pain such as is usually found in cholelithiasis. On examination there was some tenderness in the right hypochondrium with localized rigidity. The liver was not enlarged. There was slight jaundice and a trace of bile in the urine. The stools were not clay-coloured. The duodenal tube was passed and a large quantity of dark turbid bile was recovered after the injection of magnesium sulphate. This greatly relieved the pain, and after repeating the draining on the next day the symptoms entirely disappeared. This treatment was carried out twice a week, until the bile became a clear golden colour and the patient continued to be completely free from discomfort.

This appeared to be a case of mild cholecystitis with considerable biliary stasis which was relieved by the use of the duodenal tube.

CASE III.

E. C., female, aged 59; married, five children. Two years before coming under observation the patient suffered from a very severe attack of acute pain in the upper right quadrant of the abdomen, which radiated to the right shoulder-blade. During this attack she suffered from jaundice. Since then she has had many mild attacks of pain situated in the same region, the onset of which has been gradual, lasting for a few hours to a few days, but has never been severe enough to prevent her working. On examination there was slight tenderness of the right upper quadrant of the abdomen on deep palpation. Otherwise examination was negative. The duodenal tube was passed, magnesium sulphate injected, and 50 c.cm. of dark viscid bile obtained. No pus cells were found on microscopical examination. This gave the patient considerable relief, and all symptoms disappeared after three such treatments.

It was considered probable that this condition was due to cholelithiasis with associated cholecystitis, and operation was advised. At the operation the gall bladder was found to be fibrosed and thickened; it contained a single stone the size of a walnut. The common bile duct was dilated, but did not contain any stones, and the head of the pancreas was fibrosed.

CASE IV.

E. C., female, aged 78; married, seven children. In 1913 the patient began to suffer from attacks of angina pectoris, which gradually became less severe under treatment. In 1918 she had her first attack of abdominal pain. This was of very acute onset and extremely severe, associated with tenderness and rigidity over the right upper quadrant of the abdomen, radiating to the back and the right shoulder. It was associated with jaundice and clay-coloured stools. These attacks recurred at irregular intervals of a few weeks. Sometimes the onset was very acute and at other times very gradual. The gall bladder was always tender and palpable during the attacks. X-ray examination revealed the presence of a single large stone situated in the gall bladder. The diagnosis of cholelithiasis and acute cholecystitis was made, but for various reasons an operation was considered inadvisable. It was decided to attempt to drain the gall bladder by means of the duodenal tube. This was found to be accomplished with ease, and the patient did not suffer any inconvenience on the introduction of the tube. During the first drainings of the biliary tract dark, turbid, viscid bile was obtained, which contained many leucocytes and bacteria of the *B. coli* group. The biliary drainage was repeated bi-weekly, the bile gradually assuming a lighter colour, being much less viscid and clearer. As the bile improved in appearance the intervals between the biliary drainage were lengthened until it was only necessary to do it once a fortnight. Since then the patient has been completely free from attacks of pain, and can now tell by the onset of symptoms of general depression and abdominal discomfort when a biliary drainage is necessary.

There seems little doubt that this is a case of cholelithiasis with associated cholecystitis, the main symptoms being due to the cholecystitis and spread of the inflammatory condition to the ducts. That biliary stasis contributed to the exacerbation of these symptoms there seems little doubt. The risks

of operation in this case would be considerable owing to the frailty of the patient's general condition and her inability to accomplish much exertion on account of the cardiac condition.

These are but examples of certain classes of cases in which biliary drainage by the duodenal tube has given satisfactory results. There seems to be no doubt that there is a definite field of usefulness for it, and more extended experience will probably give indications for its further development.

An Address

ON

THE SPREAD, PROBABLE MODE OF INFECTION,
(24) AND PROPHYLAXIS OF LEPROSY.*

BY

SIR LEONARD ROGERS, M.D., F.R.C.P., F.R.S.,
I.M.S. (RET.)

From the time of Moses the control of leprosy has been one of the most difficult medical problems of world-wide importance. Nor are the reasons far to seek, for although since the discovery of the lepra bacillus the disease is now nearly universally acknowledged to be a communicable one, yet owing to the failure hitherto to cultivate or inoculate the organism with any degree of certainty, we are still very ignorant regarding the precise manner in which the bacillus passes from one case to another; while in the absence of any reliable method of treatment it has hitherto nearly always proved impossible to detect and segregate the early but infective stages of the disease. In view of the increased powers in the latter direction which the recent progress in the treatment of leprosy has placed in our hands, I propose briefly to review the problem in the light of a study I have recently made of the literature, more especially of the last sixty years.

The Spread of Leprosy over the World.

The following is briefly the history of the spread of leprosy over the world. Historical data show it to have been present in Egypt and India about 1400 to 1350 B.C., and in China about 200 B.C., while in Europe it was unknown to Hippocrates 400 B.C.; but Aristotle described it in 345 B.C. as a rare disease, so it was probably introduced by the invasion of Darius, taking some time to spread sufficiently to attract attention. Italy was free until the return of Pompey's soldiers from the East in 62 B.C.; Galen wrote of it in Germany in A.D. 180, and it gradually spread over all Europe by the eighth to the tenth centuries. During and after the crusades it greatly increased in Europe, becoming a scourge in the twelfth and thirteenth centuries, France alone having two thousand leper hospitals and England some two hundred, this being the first great effort to control leprosy by segregation, to which the rapid decline of the disease in the latter part of the fourteenth century is attributed by most authorities, assisted in England by the famine of 1315-16 and the black death of 1349, which are believed to have caused a loss of half the population. Some anti-contagionist writers have questioned the prophylactic value of the mediaeval leper hospitals on the ground that the isolation was not sufficiently complete to stamp out a contagious disease, but in view of the prolonged close house contact usually necessary to allow of infection of leprosy, as I shall show presently, they must have been of great use, and it is worthy of note that the disease died down most rapidly in just those countries where segregation was most stringently enforced, while leprosy remains endemic to this day in outlying parts of Europe where these measures were not much used, such as Norway, Spain, Portugal, Greece, Turkey, and parts of Russia.

Very soon after leprosy began to decline in Europe it spread to the West Indies, the northern part of South America, and Mexico, being carried by infected early Portuguese and Spanish invaders, and later also spread widely by negro slaves from Africa, and Chinese and Indian immigrants after the

emancipation of the slaves; and it is interesting to note that all the evidence points to the aboriginal American Indians having been free from leprosy, while those who have always kept aloof from intercourse with Europeans still remain so. Lastly, leprosy spread to Oceania in epidemic form during the second half of last century, becoming prevalent in the Sandwich Islands in 1853, in New Caledonia in 1865—the latter outbreak certainly and the former probably beginning with immigrant Chinamen—while in 1878 the Marquesas Isles were invaded with equally serious effects. Thus the whole history is that of a communicable disease slowly creeping over the world, although it was not until the appalling character of the invasion of the Oceania Islands by leprosy became evident that the then widely held hereditary and non-contagionist doctrines of the origin of the disease were seriously questioned and its communicability gradually became generally recognized, being materially hastened by Hansen's discovery of the lepra bacillus in 1874.

Hereditary Theory of Origin of Leprosy.

Perhaps the most remarkable feature of the history of leprosy is the almost complete replacement of the world-aged contagion theory of its origin by the hereditary theory of its causation during the nineteenth century, largely based on the book of Danielssen and Boeck of 1848, who looked on the occurrence of a second case within four generations of a family—including collateral descent and ascent and irrespective of whether the parent was diseased before or after the birth of a child—as evidence of hereditary causation, and completely ignored the possibility of family or household infection; and even then had to admit some cases to be of spontaneous origin. The absence of hereditary propagation of leprosy in the descendants of Scandinavian lepers living under far more favourable hygienic conditions after migrating to the United States of America; the frequency of infection in leprosy tropical climates of Europeans free from all hereditary taint; the spread of epidemic leprosy in Oceania far too rapidly to be possibly accounted for by heredity; and the rapid loss of sexual powers of adult male lepers and want of development of such powers in adolescent males, had already greatly shaken the hereditary theory before Hansen's discovery finally established the infectivity of the disease, although the precise mode of communicability still remains unsettled and has to be discussed in the light of recorded cases.

The Communicability of Leprosy.

As the result of an analysis of answers to questions sent to a number of medical men in leprosy countries in 1862 the Royal College of Physicians of London reported leprosy "not to be contagious or communicable to healthy persons by proximity or contact with the diseased," and that there was therefore no justification for segregation measures. As the direct result of this opinion the Colonial Office issued orders stopping all action in that direction and urged the repeal of all laws empowering isolation of lepers. Yet Dr. N. C. Macnamara, I.M.S., with great experience of leprosy came to exactly the contrary conclusion from an analysis of the 107 reports from India, constituting a large majority of the total reports received by the College, further opposition to whose view was soon forthcoming from actual workers in the tropics. Thus, Drognaat-Landr  recorded a number of infectious in 1869; all the thirteen doctors reporting to the British Guiana Leprosy Commission of 1875 favoured contagion; W. Munro collected many cases and stated the whole case in favour of contagion in 1877-79; Brosse, with long experience at the Trinidad leper asylum, wrote a book on contagion in 1879, and Hillis of British Guiana, in an important work on leprosy (1881), found evidence of contagion in 67 per cent of 139 cases without heredity which he closely investigated. In 1876 Hansen refuted the hereditary theory in Norway and supported the communicability of the disease, and in the next decade Vidal, Boeck, Leloir, and Besnier took the same view in France, and, with the exception of the Indian Leprosy Commission of 1891, to which a strong anti-contagionist was nominated by the College of Physicians, but whose views were repudiated by the London Leprosy Investigation Committee who appointed them, every important leprosy conference of the last three decades has endorsed the infectiousness of leprosy, which is now generally accepted. Sir Jonathan Hutchinson's view, first put forward in 1863, that leprosy was "fish-eater's gout"—but subsequently repeatedly modified until "commensal communicability," apart altogether from fish diet, was acknowledged—is also a prebacteriological theory of only historical interest.

* Delivered before the Tropical Diseases Section of the Royal Society of Medicine.

Conditions favouring the Spread of Leprosy.

The most important of these are a low stage of civilization, such as existed in Europe during leprosy prevalence in the Middle Ages, and still persists among the poorer classes in India, China, Africa, and Polynesia, etc., and to some extent in Norway and Iceland, in the form of one-roomed houses with overcrowding and promiscuity; great sociability, as in the Sandwich Islands and in Norway at certain seasons; absence of all fear of the disease—social ostracism of leper families, on the contrary, having been followed by temporary disappearance of the disease in South Africa in 1756 (Impey) and in Louisiana in 1785 (White); a low state of morals and sexual promiscuity, as in Europe in the Middle Ages (G. Newman), and recently in Hawaii, where it is recorded that only those Europeans who had intimate associations with the natives got leprosy, and the same is largely true of British Guiana and other tropical countries; and such social customs as eating with the fingers out of the same dish and smoking a common pipe, as in Hawaii. The Chinese believe in sexual infection of leprosy, and also in benefit being derived from passing on or "selling" the disease in this way, as the ignorant in some parts of England still believe in regard to venereal diseases; but the proved discharge of lepra bacilli from the nose and mouth in sneezing, coughing, etc., readily accounts for infection through close contact with lepers, including sexual relations. Deficiency of protein and fresh vegetable diet has also repeatedly been stated to predispose to leprosy, and probably furnishes the only real basis of the badly cured fish theory; while Tonkin has pointed out that animal proteins are largely absent from the diets of the leprosy-afflicted races of Africa, India, China, etc.

Leprosy Incidence and Climate.

Leprosy is prevalent from Iceland to the equator, so that climate alone appears to have little influence on its occurrence. Nevertheless, a study of the rates per mille that I have collected shows that very high leprosy incidence, such as 5 per mille and upwards, only occurs within the tropical zone in places with a high rainfall, nearly always from 60 to 80 inches or more a year, thus having a hot moist climate, which may very possibly be favourable to the survival of the lepra bacilli for a longer time outside the human body, facilitating infection. Thus, in Central Africa we have recent records of rates per mille of 5.0 in French Guinea, 5.2 in North Nigeria, 13.0 in French Equatorial Africa, 20.0 in Abyssinia, 20.3 in the Kameruns, and 60.7 on the Ivory Coast; in Asia, 10.7 in the Dutch East India Island of Amboina, and, according to Kermarant, 44 in the Straits Settlements; in Oceania, 26.0 in New Caledonia, 35.0 in the Loyalty Islands, and 66.7 in the Marquesas Islands, while in Hawaii the rate has been 11.88; in tropical America we have records of 5.1 in Barbados, 16.0 in Trinidad, 20.0 in French Guiana, and 25.0 in Dutch Guiana, all appallingly high incidences when we recall that in India, where lepers can be seen daily in the streets of all large towns, the rate is barely 0.5 per mille.

Between the tropics and 35° latitude, as well as in some tropical countries, the leprosy rates per mille are comparatively low, such as 1.17 in South Africa and below 0.5 in Egypt, Algeria, Argentina, etc.; while in colder latitudes the highest rates I have so far found recorded are 3.0 in 1896 and 1.1 in 1907 in Iceland; 1.91 in 1856 in Norway before isolation measures were adopted; 1.94 in Japan, and 1.06 in Cyprus. In considering the influence of temperature we must bear in mind that during the long winter months of high latitudes the people are closely crowded in houses artificially warmed to a high degree, so that if the infection is mainly a house one, as I shall show immediately, the conditions of life in such cold countries as Iceland and Norway may easily be more favourable to the communication of the disease than those in places between 35° latitude and the tropics with climatic conditions favourable to open-air life during the greater part of the year, and the incidence of leprosy just described is easily understood.

Group Infections in Newly Attacked Countries.

Owing to the incubation period of leprosy commonly extending to from two to eight years or more and the insidious onset of symptoms, it is naturally exceedingly difficult to trace the source of infection in places where the disease has for long been widely prevalent, but in newly infected countries a number of striking instances are on record, such as the following: In Cape Breton Island the first case was a French woman aged 52, from whom infection was

traced to five of her children, all born after she was attacked, two grandchildren, a stepson, an attendant of one of the leper sons, and a man who had slept with one of the infected sons—three persons not related to the family being thus among the victims. In the Louisiana outbreak of 1866 a French woman was again the first leper; three of her four sons, one of two daughters all living in the same community, a nephew residing eight miles away, a young woman who nursed the first patient, and a young man who slept with one of the infected sons, were all attacked within a few years. Again, in the Memel district of East Prussia, between 1848 and 1907, no less than 78 cases of leprosy were traced to infection introduced into a previously free district by six leprosy Russians coming to reside there as servants—examples which will suffice to prove that under favourable circumstances the slow and insidious communication of leprosy from case to case can be traced. In Natal two natives returned from the Cape after living there with a leper woman and both developed the disease two years later, with the result that leprosy became widespread among all the neighbouring previously uninfected tribes, over 100 cases being known at the end of forty-two years.

Modes of Infection.

The general history of the spread of leprosy over the world and its progress in newly infected countries thus leaves no doubt that the disease is in some way communicated directly or indirectly from one patient to another through the causative bacillus. The exact mode or modes of infection, however, remain obscure owing to want of reliable methods of cultivating the organism and infecting animals with it, so we have to fall back on recorded histories of cases for indications of the conditions under which the disease is communicable, and the most probable channels of entrance of the bacillus into the human body, for the purpose of studying which I have now collected 700 instances, analysed in the following table, in which the probable source of infection was noted.

Table of 700 Recorded Cases of the Probable Source of Infection in Leprosy.

Mode of Infection.	Number.	Percentage.
Conjugal	85	12.14
Cohabiting	43	6.14
House	180	25.7
Room	35	5.0
Bed	64	9.14
Attending on lepers	139	19.87
Leper playmate	23	3.28
Close association with leper	113	16.14
Wet nurse	8	1.14
Wearing leper's clothes	3	0.43
Vaccination	4	0.59
Inoculation from leper	3	0.43

In considering these figures it is worth recalling that the stock arguments of ... were that the disease was rarely ... and to wife and vice versa, and was very rare among attendants on lepers; yet my table shows that almost one-fifth of the recorded infections fall into each of these two classes. A large number of the infections of attendants on lepers related to patients in private houses, but a fair number also took place in leper asylums and settlements, so most of these, as well as the cases of conjugal, cohabitating relationships, house, room, and bed infections, or nearly four-fifths of the whole, were house infections—just as I showed in 1897 was the case in the equally insidious infection of kala-azar—while many of the cases entered as "close association" included visiting the houses of leper friends, from whom the infection was apparently derived. Thus the outstanding feature of the analysis is that in the very great majority of the cases there were frequent and prolonged opportunities of contact in a house inhabited by a leper before the disease was communicated, although occasionally the contact was short, as in three instances in which infection was traced to sleeping on a single occasion with a leper woman, the man developing leprosy after ten months, one and two years respectively after such close contact. Many of the cases in which infection followed cohabitation between a healthy and a leprosy subject were European males living with leprosy native females in tropical countries, while a number of the conjugal infections took place in temperate climates, such as Norway. There is, however, evidence that conjugal infections are comparatively uncommon in proportion to the frequency of this form of exposure, for they were found to be only from 4 to 5 per cent. in the Molokai leper settlement of the Sandwich Islands—a fact which is explained by the greatly diminished susceptibility to the disease in persons over 30 years of age, while it

has also been pointed out that owing to male lepers soon losing their sexual powers their wives are then little more exposed to close contact with them than other members of the household. The infections among playmates were mostly European children associating with native leper children, and it is generally recognized that children and adolescents between 5 and 20 years of age are especially susceptible to the disease.

The house infections include many persons who occupied the same room or even the same bed as a leper, and the numbers occupying the same room must in reality have been far more numerous than the 5 per cent. shown in my table, as so many of the house infections occurred in the poorer tropical races whose houses only contain one room. Further, no less than 9.14 per cent. of the wholesies were actually recorded as having occupied the same bed as a leper, apart from conjugal and cohabiting couples, the addition of whom brings the known bed infections up to no less than 27.42 per cent.—a most striking fact which well brings out the long and close contact commonly necessary before infection takes place between the diseased and the healthy. The cases of infection from wet nurses are also of interest in this connexion, and several times showed very prolonged incubation periods.

Is Leprosy Commonly Conveyed by Inoculation?

When we come to consider the precise manner in which the leprosy bacillus gains access to the human body we encounter great difficulties, as it may well be either through their ingestion in food or by inoculation through some minute abrasion in the skin or in a mucous membrane, such as that of the nose, mouth, and gastro-intestinal canal, as in many cases of tuberculosis. In my studies of leprosy literature I have been struck by the number of authoritative writers on the subject, such as Hansen, Hillis, Mauro, Arning, etc., who are strongly in favour of inoculation being the ordinary mode of infection; while there appears to be little or no clear evidence in favour of ingestion of the bacilli in food producing the disease, for a marked feature of its incidence is the capricious manner in which only one of a number of healthy persons of a household containing a leper is attacked by the disease within a short time, which is more easily understood if infection is due to the accidental entrance of the bacilli through some minute abrasion of the skin or mucous membrane than if the organisms are ingested with contaminated food of which many of the household are likely to have partaken. The frequency with which anaesthetic leprosy beginning in the lower extremities has been observed in bare-footed races, as in Crete, Java, Abyssinia, the Sudan, etc., is only readily explainable on the inoculation theory, as are the cases in which leprosy has been recorded to have been contracted by wearing leper's clothes; while Tonkin has associated the high incidence of the disease in Trans-African Sudan stretching across from the south of Egypt to Northern Nigeria with the prevalent custom of clothes being passed on from the well-to-do to poorer and poorer persons until threadbare, without ever being washed.

Of great significance in this respect is the strong suspicion that in rare instances leprosy has been transmitted by arm-to-arm vaccination, as in Professor Gairdner's cases of a European child developing leprosy after being vaccinated from a native child of leprosy family in the West Indies, and another European child vaccinated from the first showing the disease after his return to England; and those of Hillis in which a brother and sister of a Portuguese family both got leprosy after vaccination from the same source. Exaggerated statements have, however, been made regarding this danger in the West Indies, but in the Sandwich Islands leprosy did undoubtedly spread widely after very carelessly performed wholesale vaccination during epidemic small-pox in 1852 (Daland); it is also on record that in parts of the Sandwich Islands leper centres developed after vaccination in numerous places where it previously had been unknown, and the same relationship has been reported in Mexico. Moreover, Arning in Hawaii readily obtained lepra bacilli from vaccine vesicles raised in leprosy subjects; Boven Rako's negative results were all in anaesthetic cases with few bacilli, while he found acid-fast bacilli in the one nodular case he tested. This disaster is easily prevented by the modern method of using calf vaccine.

Although, with the exception of Arning's disputed Hawaii criminal, the results of the experimental inoculation of man with lepra bacilli have been negative, probably on account of the subjects being over the age of the greatest susceptibility

to the disease, yet there are cases on record which practically amount to positive inoculation experiments, such as the following. Professor Ehlers records the case of a Danish doctor wounding his finger during an obstetrical operation on a leper negress, followed by slow healing, and after a comparatively short incubation period anaesthetic leprosy, beginning in the wounded finger, appeared. In a second case a doctor wounded himself in opening an abscess of a leper and subsequently developed the disease; while I met with a case in India of a doctor who attributed his disease to operating on a leper, and who also had extensive anaesthetic lesions of one hand in addition to numerous macules. Equally striking are two tropical cases, in each of which a leper boy inserted a sharp instrument into his flesh and a European playmate immediately afterwards ran the same instrument into his limb, both developing leprosy in a comparatively short time, only a few months in one of them, with acute febrile onset and macules. Such a series, together with cases such as Larey's in which persons with wounds got leprosy, taken with all the preceding evidence, makes me think that the common mode of infection is the inoculation of the bacilli through minute accidental lesions in the skin, and possibly also in the nasal or oral mucous membranes; in further support of this view we have the instructive observations of Leboeuf in New Caledonia, who found acid-fast bacilli on the skins of seven out of twenty-nine healthy persons living with lepers, two of whom actually developed the disease later. Much work has been done on the question of the possibility of transmission of the lepra bacilli through the bites of insects, with inconclusive results, but it is still very possible that it may be so carried. It also appears to me to be very significant that lupus, which is recognized to be an inoculated dermal tuberculosis, so closely resembles some individual forms of leprosy eruptions both in appearance and chronicity, while the practical limitation of leprosy lesions to the connective tissues of the skin and nerve sheaths indicate the deeper layers of the skin and possibly of the nasal mucous membranes as the probable site of the primary infection, although once the infection is fully established the bacilli may undoubtedly be disseminated through the blood stream.

THE PRINCIPLES OF PROPHYLAXIS AND CAUSES OF FAILURES.

The foregoing considerations make it clear that the first essential in prophylaxis is the removal of all infective cases from frequent and close contact with the healthy, especially the most susceptible—that is, children and young people up to 20 to 30 years of age. By far the most infective type of leprosy is the tubercular form, including mixed cases, with discharge of large numbers of bacilli from the nose and breaking-down nodules; while anaesthetic cases, especially chronic mutilated ones, who have often lost all infectivity, are comparatively innocuous, yet they coöperate the great majority of inmates of Indian and other leper asylums on account of their helplessness, although their isolation is of little value in preventing new infections. It is significant that in the recent epidemic outbreaks in the Pacific islands tubercular cases have predominated, and that in the successful segregation measures in Norway great attention was paid to isolating the tubercular cases in hospitals, and home isolation under close medical supervision was mainly confined to the slightly infective nerve form.

The safeguarding of children and young persons from contact with lepers cannot be too strongly insisted on, as I have elsewhere shown their great susceptibility. This view is also held by Professor Lie of Norway and other authorities, so the children of lepers should be separated from their infected parents at birth whenever possible, and marriages of lepers, at any rate of the child-producing ages, should be prohibited, for McCoy has shown that the fecundity of female lepers is little if at all reduced. There is less objection to an adult of over 30 voluntarily accompanying his or her conjugal mate to a leper colony, as infection is then comparatively rare.

When we come to enforcing segregation we meet with great practical difficulties, as the necessary compulsory legal powers must be so tactfully exercised as to obtain, if possible, the co-operation of the people to prevent extensive hiding of cases vitiating the results. In the absence hitherto of any efficient treatment of leprosy isolation measures have frequently failed, partly owing to many cases not being detected until years after the onset of the disease, and partly from inefficiency and want of continuity in carrying them out. Time will only permit me to mention a few illustrative examples,

although I hope before long to be able to deal more fully with the whole subject of leprosy. Thus, in Creto there are leper villages just outside the large towns whose inmates have to beg for their livelihood, and Ehlers found that some made enough money to buy their houses in the leper villages, and then let them to healthy people while they went on begging tours; while in South Africa the accommodation was for long totally insufficient to isolate even the small proportion of lepers who wished to be admitted; yet Hutchinson quoted these two instances as failures of segregation in support of his non-contagious theory of leprosy. Again, failures, from isolation measures being relaxed or discontinued as the direct result of the unfortunate 1865 College of Physicians report, are recorded in British Guiana, St. Kitts, and in Dutch East and West Indian Islands, and similar vacillations of policy led to former failures in French Guiana, Iceland, New Caledonia, etc. Want of compulsory powers led to very slow progress in stamping out a focus of leprosy in New Brunswick, while political influence prevented the full use of compulsory powers in Louisiana. In the Sandwich Islands little progress was made until the segregation laws were more rigorously enforced under American influence, when much more satisfactory progress was made, and in the French possession of New Caledonia village segregation largely failed for want of sufficient influence of the native chiefs, but the same system met with considerable success in the French Marquesas Islands with the help of the military power of authoritative chiefs. In Norway, on the other hand, patient persistence in a sound policy of isolation commenced on a voluntary basis in 1856, when leprosy was on the increase, and made compulsory in 1885, had reduced the lepers by 1900 to only 6 per cent. of the former numbers, and Hansen showed that the number of "new cases"—that is, persons in whom the disease had commenced within three years of their being found—was in each quinquennial period in almost mathematical proportion to the number of remaining centres due to unisolated lepers in the districts, proving that the disease declined as the infective centres were reduced. Yet Norwegian experience showed that only 1 case in 5 was discovered and isolated within the first three years of the appearance of the symptoms, thus largely accounting for the slow progress in stamping leprosy out of Norway; and if this is so in a European country with numerous medical men, it will necessarily be much more difficult in medically backward and poor tropical countries such as India, Hawaii, and the Philippines; so it is not surprising that such a statement as that of Bayou that new cases of leprosy had been reduced by 90 per cent. within a few years of segregation being enforced in the Philippines have not been borne out by later official figures showing the yearly discovery of many cases. It would, however, be interesting to know what proportion of the present yearly admissions to the Cullion settlement are "new cases" in the Norwegian sense and how many are old long-hidden lepers. A careful study of the above instances and of the whole recent literature of leprosy has convinced me that so long as lepers have the strongest possible incentive to hide their disease as much as possible to avoid life-long imprisonment without hope of cure, so long will it be a very prolonged, difficult, and expensive procedure to stamp out the disease by the only effective measure—isolation of the infective sick from the healthy.

The Value of Improved Treatment as an Aid to Prophylaxis.

This brings me to my last and most important point. Now that we possess in the soluble preparations of the active unsaturated fatty acids of chaulmoogra, cod-liver, soya bean, and other oils introduced by me, a reliable method of clearing up the bacillus-bearing lesions of leprosy, with loss of infection, including cessation of the discharge of the organisms from the nose, lepers have for the first time a powerful incentive to come forward for treatment as early as possible instead of hiding their terrible calamity. There is already clear evidence, both in Honolulu and in India, that early cases are declaring their disease and asking for the new treatment, which is the most revolutionary and hopeful sign in the age-long conflict with this dreadful scourge, all the more terrible on account of its insidious onset and prolonged disfiguring course; so I would urge that the time is ripe for renewed efforts under the present favourable conditions to deal more effectively with leprosy with a view to lessening its incidence and eventually stamping it out. In Honolulu scores of cases have already been discharged from the hospital, apparently cured, under parole, and good progress

is also being made elsewhere, especially by medical missionaries in charge of Indian leper asylums, in spite of their cases being mostly very advanced ones, with the result that at Ditchpali, for example, earlier cases are now flocking in for the new treatment. The various Indian Provincial Governments are also taking up the provision of leper settlements with ample land in the country in place of the prison-like town asylums. Bengal has already acquired 240 acres for this purpose at the cost of a liberal Indian gentleman, and the Legislative Council has recently voted a larger grant than the Indian Minister originally proposed owing to financial stringency, and it is hoped before long to be able to accommodate 1,000 lepers, with a cottage system for earlier cases, a hospital for advanced maimed ones, and a separate part for healthy children of lepers; and when patients begin to return to their homes after successful treatment the demand for accommodation is likely to exceed even that now being provided, although with the simplified intramuscular injections of the ethyl ester preparations it will also be possible to treat numbers of early cases at hospitals. With several hundred thousand lepers in India alone, and probably one or two millions in the world, including those among the dense populations of China and Africa, the task is great; but once a fair proportion of the earlier and more amenable cases receive regular treatment, rendering them no longer infective to their households and neighbours, new cases should gradually decrease, while the advanced and helpless cases will die out by degrees, and slow but sure progress will be made in reducing the incidence of perhaps the most dreadful disease to which human flesh is heir.

ACUTE INFLAMMATION OF A LARGE DIVERTICULUM OF THE JEJUNUM WITH PERFORATION.

BY

GRAHAM W. CHRISTIE, M.C., M.B., F.R.C.S. EDIN.,
LATE RESIDENT SURGICAL OFFICER, ANCOATS HOSPITAL, MANCHESTER.

The following case presents many points of clinical and pathological interest.

On February 3rd, 1922, I was asked to visit a married woman, 48 years of age, who the day previous had been taken ill suddenly with acute abdominal pain and had vomited several times. Her bowels had not moved during the last forty-eight hours. When I saw her she did not look ill; the pulse was 96 and the temperature 99°. She was of good general condition, excepting that she was somewhat flabby. She complained of acute pain in the left side of the abdomen, below the umbilicus. At the site of the pain there was distinct tenderness on palpation and a suspicion of slight rigidity, though I could not be certain, as she was fat. On deep inspiration I could feel a round mass, somewhat larger than a tennis ball, about midway between the umbilicus and the symphysis pubis, just to the left of the middle line. The lump was hard and of the consistence of a uterine fibroid, though it was extremely tender. Vaginal examination did not offer any assistance in diagnosis, and per rectum no fullness could be felt through the pouch of Douglas. The swelling was not particularly mobile; though it was circumscribed.

There did not appear to be any urgency to explore the abdomen, so I kept the patient under observation and treated the abdomen and enemata the condition swelling, however, still remained tender, was becoming smaller from day to day. There was no sickness or vomiting after the first twenty-four hours. When the condition had more or less subsided I advised operation, and this I performed fourteen days after the onset of the acute phase of her illness.

Previous History.

For years she had suffered from flatulence. She had also been subject to recurrent attacks of colicky pain in the abdomen which periodically had necessitated a day in bed. These attacks had been much more frequent during the last year. Her bowels had always been regular and she had never had attacks of sickness. She had no children. Menstruation had always been scanty and she had never missed a period during her twenty years of married life. Her general health had been good.

Operation.

On February 16th, 1922, I explored the abdomen by a mid-line incision below the umbilicus. On opening the peritoneum a quantity of serous peritoneal fluid escaped. About the centre of the abdomen to the left of the middle line was a mass somewhat larger than a tennis ball and entirely covered with a thick layer of omentum. When the swelling was slowly denuded of its omentum there was exposed a large spherical swelling, tense and fluctuating, about the size of an apple, springing from the antimesenteric border of a loop of small intestine. While separating the omentum at one point, a large gangrenous patch was disclosed on the fundus of the swelling, with a perforation in its centre through which very foul-smelling pus and semi-solid contents escaped. It was

now obvious that this was a condition analogous to acute inflammation of a Meckel's diverticulum, which had perforated sooner or later, but which had fortunately been closed by the omentum. The swelling was due to the diverticulum with patches of adherent omentum excised. The wall of the gut was closed in the ordinary way. It was now found that the lumen of the gut at the site where the diverticulum had been excised was constricted and it was considered essential to make a lateral anastomosis. In seeking the ileo-caecal junction the ileum was traced backwards and the origin of the diverticulum from the jejunum about nine inches below the duodeno-jejunal junction established. A lateral anastomosis was now done between the short loop of jejunum above the site of the diverticulum and a loop below. The areas of intestinal suture were covered with free edges of omentum. The pelvic organs, appendix, and other viscera were normal. The abdomen was closed in layers without drainage.

The diverticulum excised was about the size of a Tangerine orange. The long axis of the lumen of its pedicle was about one inch in length. At its fundus there was a gangrenous area, through which very fetid pus could be expressed. To the naked eye the wall of the sac seemed to be of the same structure as the wall of normal small intestine. The periodic attacks of colicky abdominal pain may quite conceivably have been due to peristaltic emptying of the contents of the diverticulum into the lumen of the jejunum. At the time of operation, before opening the abdomen, it was noted that the "tumour" was at a slightly higher level than at the time when I first saw the patient, due, in all probability, to shortening of the omentum in its defensive process. Except for some vomiting of coffee-ground material during the first twenty-four hours after operation, the patient made a good recovery.

My thanks are due to Dr. J. T. Bailey for his kind assistance at the operation, and to Dr. H. Grimshaw, resident medical officer, Stepping Hill Hospital, for giving the anaesthetic.

TEMPORO-SPHENOIDAL ABSCESS.

BY

JAMES ADAM, M.A., M.D.,

SURGEON FOR DISEASES OF EAR, NOSE AND THROAT, GLASGOW ROYAL INFIRMARY.

It has been suggested by those who saw and were interested in this case of left temporo-sphenoidal abscess that a note of it might be useful.

The main points of interest were: (1) a large perisinus abscess which seemed sufficient to account for the symptoms noted on admission; (2) the extent of the intracranial abscess (there were in fact two)—the bulk of the lobe must have been involved; (3) this was not opened till twelve days after admission and must have gone on enlarging under observation in hospital, yet there were none of the classical signs of brain abscess till within twenty-four hours of its being opened: pulse and temperature were up; there was no complaint of headache or vomiting after admission; no paresis, sensory aphasia, or optic neuritis.

A girl, aged 8, was admitted to Glasgow Royal Infirmary on December 10th, 1921, with a history of discharge from the left ear dating from an attack of scarlet fever eight months previously; chills and pains in the left side of the head had confined her to bed for a fortnight. Examination showed discharge from the left ear, postero-inferior perforation, great tenderness over the mastoid; the temperature was 98.8°, pulse 103. The same day the mastoid was excised and a large perisinus abscess opened; pus under considerable pressure exuded from all around the sigmoid and through the mastoid emissary foramen. The sinus was exposed for fully an inch, but seemed healthy; the tegmen was eroded. Next day the temperature was 101°, and for the following four days ranged between 99.5° and 100.5°; the pulse from 95 to 120. The child was listless and obviously ill; the wound remained dry, glazed, and unhealthy. On the seventh and eighth days after admission the temperature kept normal, pulse 96 to 115; the wound looked a little better. On the ninth day the temperature rose suddenly in the afternoon to 103.5°; in the evening it had fallen to 97.5°. I went the following morning expecting to deal with a sinus thrombosis, but the picture was quite other and plain. On the left side there was total paralysis of the third nerve; on the right, facial paresis, weakened hand-grip, becoming more distinct later in the day; ankle clonus; abdominal reflex absent, no Babinski. Eye grounds normal. Cerebration becoming quickly duller.

Operation (at noon) was, in deference to opinion expressed in consultation, limited to completion of radical mastoid operation, removal of whole tegmen (dura seemed sound in appearance and exploration by probe), and lumbar puncture (15 c.c. clear fluid under pressure, some leucocytes, no organisms). Temperature at 4 p.m. 96.2°, pulse 92; child listless but conscious. At 10 p.m., after trephining an inch above and half an inch behind the posterior menal wall and enlarging the opening, a knife passed inward and slightly forward to the depth of about half an inch gave vent to stinking gas and about two ounces of pus. Next day, after the cavity had been washed free of stinking pus, a probe used to explore the cavity luckily opened a second abscess on the

posterior wall and let out quite half an ounce of pus. For the useless gauze pack employed during the first twelve hours Horsley's concentric tube drain was substituted and retained twelve days, the cavity being gently irrigated once or twice daily with saline. After removal of the tubes gauze was inserted for a few days till the cavity closed.

Sensory aphasia, which doubtless was present on the day the paralysis appeared or earlier but was obscured by the mental dullness, was noted forty-eight hours after operation, but within a week had passed off, as had the other parietic signs, except those due to the third nerve. The pupil reacted slightly on the tenth day after operation, but three months later remained slightly larger than its fellow.

The child, who had seemed to be dying, made a perfect recovery, and from a week after the abscess was the merriest patient in the ward. Whisper was heard with the left ear at 10 feet.

Comment.

The case was probably rather one of slowly spreading encephalitis than one of strictly encapsulated abscess. In view of this and the extent of the suppuration the result is encouraging. Instead of the usual crucial incision a simple slit was made in the dura to avoid hernia, which did not occur, and in spite of the size of the cavity proved, together with irrigation, ample for drainage. The temptation was strong to make a counter opening in the tegmental region, but when there is no obvious track in the dura the result seems to show that the squamous route is preferable because it is clean, can be made efficient when an abscess is found, and comparatively safe when the abscess is missed. Lastly, the case confirms MacEwen's dictum that in cases of crossed paralysis the lesion is subcortical when the contralateral paralysis affects the face more and earlier than it does the arm, and the arm more than the leg; whereas, when the lesion is close to the pons the contralateral paralysis is comparatively uniform and simultaneous.

The diagnosis of cerebral abscess is admittedly often difficult; certainly it ought not to be rushed. The following case is an interesting contrast in regard to pathology and treatment. It remained a diagnostic puzzle. Whereas in the preceding case the aphasia was sensory, in this one it was motor, and one of the main points which put abscess out of court.

J. R. was admitted to the infirmary on January 11th, 1921, with a history of discharge from the left ear for twelve years, attacks of giddiness for one month, occipital pain for a fortnight, and aphasia for a week; there had been no sickness or vomiting. Both family and personal history was good; there was no suggestion of syphilis in patient, wife, or children; Wassermann test negative. He continued at work after aphasia started till it became so pronounced that his mates sent him home. He was a bright, intelligent, well-nourished man, understanding all that was said, but having difficulty of utterance, though able after a struggle to make himself understood; he could sometimes spell what he could not articulate, and named objects shown to him. The left ear was stone deaf; meatus blocked by a polyp and pus; there was slight paresis of the face on the right, affecting more the lower muscles; the right grip was feeble than the left. Temperature, pulse, and cerebration were normal. In fundus of left eye veins more congested and disc whiter than on right.

On January 12th a radical mastoid operation was performed; the antrum was large, and without obvious pus; the tympanum was full of granulations, incus absent; the tegmen was unusually thick and quite healthy, as also was the dura. Because of this, and because the cerebral lesion was obviously as far forward as Broca's lobe, the brain was not punctured. Within the following week the cerebral symptoms steadily increased, speech becoming quite unintelligible—even "Yes" and "No" were not properly articulated; agnosia increasing, patient could at first write his name and address, but not occupation; the tongue protruded to the right; he had paresis of face, arm, and leg on the right side; biceps-jerk and knee-jerk were greater on right; the abdominal reflexes were lost on the right. He remained bright and seemingly intelligent, indicating by a nod when his own occupation was mentioned amongst others. On the fifth day after admission both optic discs were red; grey striation of retina round the discs was equal in the two eyes, but in the right there was more obscuration of vessels at the disc edge; later this became more equal (Dr. Garraway).

A month after admission the paralysis was improving, and had passed off in another month. No disturbance of pulse or temperature was noted throughout. The patient at time of writing remains normal, except for loss of hearing in the left ear.

Comment.

The case was certainly not one of lethargic encephalitis, meningitis, or syphilis. Subdural haemorrhage was suggested; I can think of no other diagnosis; but the development, spread over two or three weeks, was strangely slow for haemorrhage. Of doubtful value therapeutically, and perhaps risky because there were no pressure symptoms, a spinal puncture might have helped the diagnosis.

CARBONIC OXIDE IN TOBACCO SMOKE.

BY
PROFESSOR HENRY E. ARMSTRONG, F.R.S.

WHEN recently the carbonic oxide scare was raised in the press, the danger we incur, even in the streets, from the constant discharge of the exhaust gas from bus and motor-car engines was a matter of scarcely joking comment. Some of us, knowing the secrets of combustion, were moved to suggest to tobacco-using friends that they were risky companions. The subject of cigarette smoking was discussed in these columns in November last* by my friend Professor W. E. Dixon, F.R.S. I learn from him that he has regarded the pernicious result of excessive cigarette smoking as an effect of carbonic oxide but that he is inclined to attribute the obvious effects of cigar smoking rather to the influence of nicotine, if not to other basic products of the destructive distillation of the noxious weed.

Apparently the gases from the burning cigar have not been specially examined for carbonic oxide. Discussing the matter with my neighbour, Mr. E. V. Evans, chief chemist to the South Metropolitan Gas Company, we came to the conclusion that it was worth while for once to make a few experiments on combustion of a practical character, to ascertain the extent to which poison-gas manufacture is indulged in by the public; at his invitation I have participated in the work. We advisedly do not call it a research, as the results are sufficiently striking to be of public interest and the work has been done without Government grant.

Sulphuretted hydrogen and prussic acid are both constant products of the smoker's activity, though in very minute proportions. This is easily demonstrated by smoking a cigarette in a glass-tube-holder into which a strip of test paper is first inserted, then a closely plug of cotton-wool and finally the cigarette. Acetate of lead paper is blackened after a few whiffs; similarly, after removal of sulphuretted hydrogen, a paper impregnated with a solution of orthotolidine in cupric acetate and water—a most delicate test for hydrogen cyanide—rapidly turns blue. The less sensitive picric and Prussian-blue tests are more slowly effective.

The blood test for carbonic oxide, in our experience, cannot be applied effectively to smoke—something is present which mars the colour change; it can only be used after scrubbing the smoke by means of cotton-wool, fuming sulphuric acid and a concentrated solution of caustic soda.

The following results were obtained by smoking a cigarette or pipe, by attaching it to a gas-sampling bottle and allowing mercury to run out in "puffs."

	"Gold Flake."	"Player's Weights."	"Sylvion" (Virginian).	"Medium Shag" in Pipe.
CO ₂	% 4.50	% 7.02	% 4.25	% 10.15
CO	0.89	1.24	0.97	1.14
O ₂	16.20	15.60	16.54	10.53

The oxygen may be taken as a measure of the excess air. Multiplying the values by 5, it appears that about 80 per cent. of air in excess was drawn through the cigarette and only about 50 per cent. through the pipe.

* BRITISH MEDICAL JOURNAL, November 19th, 1921, p. 819 et seq.

A cigar smoked in a similar way gave the following most surprising figures:—

CO ₂	13.36 per cent.
CO	5.8 "
O ₂	5.8 "

The amount of air in excess was under 30 per cent., showing that the cigar is a very efficient instrument. Both the amount and the high ratio of carbon monoxide to dioxide

$$\frac{13.36}{5.8} = 2.3$$

are remarkable.

In these experiments the gases were analysed directly in a Bone and Wheeler apparatus. The percentage of monoxide being so small from the cigarette, we deemed it advisable to use Gautier's perhaps more trustworthy method (for small amounts), in which the purified gas is passed over heated iodine pentoxide; the iodine liberated in oxidizing the carbon monoxide being determined by titration. To ascertain the effect of smoking more or less rapidly, the rate at which mercury was run out was varied considerably. The percentages of carbonic oxide thus estimated came out as follows:

	CO
1. Turkish cigarette (smoked normally)	0.72
2. Virginian cigarette (smoked normally)	0.673
" " " "	0.714
" " " "	0.78
3. "Wild Woodbine" cigarette (smoked slowly)	0.6
" " " " (smoked normally)	0.875
" " " " (smoked quickly)	1.40
4. "Three Nuns" tobacco (bowl of pipe cool, sampled shortly after lighting up)	1.14
5. Player's "Tawny" (pipe; beginning of smoke)	0.9
" " " "	0.7
6. Havana cigar (smoked quickly)	8.13
" " " "	6.0

It is clear from these results that the proportion of carbonic oxide in the smoke will vary according to the rate of smoking. When air is drawn in rapidly the length and temperature of the glowing portion are increased and more of the monoxide is formed. In general, however, a normal sample of cigarette smoke will contain between 0.5 and 1 per cent. of carbon monoxide.

In all these trials the smoking was artificial. In a final series cigars were smoked in the usual manner but the smoke drawn into the mouth was afterwards expelled into a mercury receiver and then analysed. The cigars used were a set specially selected for me by a friend who is a maker. The results in column A of the following table apply to smoke obtained by mercury suction; those in column B represent the effect of normal smoking. X is the ratio of dioxide to monoxide. The high proportion of air in two cases in the B series is to be ascribed, we think, to the mouth not fitting the cigar (a big one) closely. It will be noticed that, in the A series, the old, well-matured cigar seems to have offered a specially free passage to air and that this gave the lowest proportion of carbonic oxide. The irregularities in the results need not be taken too seriously, being doubtless in the main due to the irregular character of the operation of smoking as it was practised in these trials.

Apparently the results are little affected by make or quality; closeness of packing and rate of smoking seem to be the determining factors. In the A series the cigar was only smouldering; in the B series the length of the burning portion was greater and the proportion of monoxide is usually higher. It would seem that the "strong" smoker produces

Comparison of Cigars of Different Quality.

the greater amount of carbonic oxide by maintaining a longer layer of the cigar red-hot.

It is of interest to compare the proportions of carbonic oxide in straight coal gas, made by simply distilling coal, with that in tobacco smoke.

A cigar of average size was smoked under such conditions that the volume of smoke formed could be measured. Four-fifths only of the cigar was smoked in order to make allowance for the portion of cigar usually discarded. It was found that 0.303 cubic foot of smoke was produced, of which 7 per cent. was carbonic oxide. The quantity of straight coal gas containing an equivalent amount of carbonic oxide is 0.25 cubic foot—that is, 1 cubic foot of straight coal gas contains an amount of carbonic oxide equal to that in the smoke from four cigars; the proportion of carbonic oxide in South Metropolitan gas, it may be added, is about that of average cigar smoke.

As to the effects of smoke, the cigarette smoker often has the habit of inhaling; but as a rule pipe and cigar smokers do not; friends tell me that pipe and cigar smoke are nauseous when inhaled: apparently volatile products of distillation are carried forward much more than in cigarette smoking and these protect the cigar smoker notwithstanding the larger production of carbonic oxide. The blood of the cigarette smoker often shows signs of carbonic oxide absorption. A friend, who is an excessive smoker, is said to have 5 per cent. of his blood out of action; another who is an equally great smoker and inhales constantly shows no sign of absorption. The latter is an exceptionally vigorous person, who eats and drinks freely; apparently his is scarcely a case of tolerance: if carbonic oxide enter his blood either it is swept out without difficulty by gaseous exchange or is worked up in some way. Apparently there is room for further study of the conditions regulating the natural exchange of carbonic oxide for oxygen in the blood. Smoking has its interesting side, even for the non-smoker.

We have to thank Mr. Pickard and Miss Bucknell for the very skilful aid they have given and the special interest they have taken in this little experimental excursion.

OBSERVATIONS ON THE AMOEBCIDAL ACTION OF CONESSINE.

BY

H. C. BROWN, C.I.E., M.B., B.CH.CAMB.,
MAJOR I.M.S. (RET.).

(From the Wellcome Bureau of Scientific Research.)

THE bark and seeds of *Ho'arrhena antidysenterica* have been held to rank amongst the most important medicines of the Hindn materia medica for many centuries; in fact Garcia de Orta, who wrote in 1563, speaks of their great merit in the treatment of dysentery. The plant is a small deciduous tree found throughout India and Burma, belonging to the Apocynaceae; according to Sir George Watt,¹ it has been confused with another species, *Wrightia tinctoria*, belonging to the same family.

From *Wrightia antidysenterica*, Stenhouse,² in 1864, isolated an amorphous base forming amorphous salts. Hains³ had previously obtained the same alkaloid and described it under the name of "conessine."

The alkaloid conessine is now a commercial product prepared by Merck, and the formula $C_{14}H_{19}N$ is given to it. In the United States Dispensatory, nineteenth edition, it is stated that the medicinal properties of this substance have apparently not been investigated.

In 1880 Baboo Rakhil Das Ghose⁴ described *Holarrhena antidysenterica* (Wall) as being synonymous with *Wrightia antidysenterica*, and from the seeds he obtained an alkaloid, which was isolated by Baboo Ram Chandra Datta, which the latter called "kurchiacin." He found it useful in cases of chronic dysentery, and used it in doses of 2 to 5 grains.

Burn⁵ gives an account of the physiological action of conessine, holarrhine, and oxyconessine, and Pyman⁶ in 1919 described the chemical properties of holarrhine and conessine. Apart from the study of the physiological action of the alkaloid by Burn no attempt has apparently been made to study the action upon the causative agents in dysentery.

The remedy is chiefly used in Northern India in the form of an infusion of kurchi, this being the Bengali name for the plant. The efficacy of this infusion in certain cases of dysentery is, in the opinion of those who have used it, little short of miraculous, and it seems strange that although

conessine has been isolated for more than half a century the amoebicidal action of this drug has apparently not been tested. I have seen two cases in which its effect was very striking, in one of them dramatic. It may be that, as Burn pointed out, although the alkaloid possesses the properties of a local anaesthetic it cannot be used as such, at any rate by the hypodermic route, owing to the production of a necrotic area at the site of the inoculation; the necrosis is apparently quite independent of secondary contaminating organisms and is produced even with doses of 10 milligrams.

The preparation with which the following experiments were made was in the form of a neutral solution of conessine sulphate, originally isolated by Dr. Pyman from a sample of *Holarrhena congolensis* obtained from the Belgian Congo; a regular supply has been sent to me through the kindness of Dr. Heury, Director of the Wellcome Chemical Research Laboratories.

In the first place an attempt was made to ascertain whether the alkaloid had any specific bactericidal action on bacilli of the dysentery group. It was found that although the drug did exert some specific action *in vitro* such large doses had to be used as to place any chance of cure of bacillary dysentery by this means outside the bounds of probability, and the rest of the investigation was directed to the action of conessine upon the growth of amoebae.

As it was not found possible to obtain suitable material from an acute case of amoebic dysentery with which kittens might have been infected and the strain maintained, the action of the alkaloid was studied upon cultures of free-living amoebae which had been isolated from pond water by Dr. Wenyon; for these cultures, and for his valuable suggestions and guidance, I wish to express my best thanks. The cultures of this strain of amoebae were maintained upon an agar medium (Walker's medium) upon which the amoebae grew luxuriantly at room temperature.

There is a great deal of discrepancy in the published statements as to the results obtained by different observers when studying the amoebicidal action of emetine upon material from the intestinal contents in which *Entamoeba histolytica* was present. For instance, Leonard Rogers⁷ states that when a small piece of mucus containing these active amoebae was placed in saline solutions of emetine of the strength of 1 in 10,000 the organism was immediately killed, and that even in a 1 in 100,000 dilution they were rendered inactive and apparently killed after only a few minutes' immersion. Dalo and Dobell,⁸ however, found that certain of their strains of *Entamoeba histolytica* survived the action of 1 in 1,000, and even 1 in 100 emetine for periods up to one hour. Further, Wenyon and O'Connor⁹ showed that amoebae in pus treated with a 6.5 per cent. solution of emetine could remain alive for several minutes.

Of course it is not possible to say that the conditions of the test in each case were exactly comparable, and it appears that the relative differences in the amount of intestinal mucus present may be a variable factor in the experiments. This intestinal mucus is capable of interfering with the action of emetine, as is shown in the following experiments.

Experiment I.

A 1 per cent. solution of conessine sulphate and a 1 per cent. solution of emetine hydrochloride were made. Of these 5 c.cm. was placed in two small centrifuge tubes, then to each tube an equal amount of intestinal mucus was added, the quantity of mucus being approximately 1 c.cm. The mucus was then beaten up for five minutes and the tubes centrifuged for five minutes. From these emetine solutions were made and then 1 c.cm. of the melted agar contents poured into Petri dishes, and the surfaces planted with a saline suspension of amoebae.

Emetine Hydrochloride concentration in the Medium.	Bacterial Growth.	Amoebic Growth.	Conessine Sulphate concentration in the Medium.	Bacterial Growth.	Amoebic Growth.	Control.
0.1 %	++	0	0.1 %	++	0	Bacterial growth) ++
0.01 %	++	0	0.01 %	++	0	
0.001 %	++	++	0.001 %	++	++	Amoebic growth) ++
0.0001 %	++	++	0.0001 %	++	++	

Experiment II.

This experiment was repeated as above, only in this case a four hours' contact was allowed between the mucus and the reagents, with the result shown in the following table.

Emetine.	Bacterial Growth.	Amoebic Growth.	Conessine.	Bacterial Growth.	Amoebic Growth.	Control.
0.1 %	++	+	0.1 %	++	0	Bacterial growth } ++ Amoebic growth } ++
0.01 %	++	++	0.01 %	++	++	
0.001 %	++	++	0.001 %	++	++	
0.0001 %	++	++	0.0001 %	++	++	

From the above two experiments certain deductions can be made. In the first place it is clear that the amoebicidal action of these alkaloids is considerably lessened if the solutions of the alkaloids are brought in contact with intestinal mucus. The time of contact is an important factor, and one sees that after four hours' contact the amoebicidal action of the alkaloids is practically destroyed. Another point here shown is that the conessine is distinctly antagonistic in its action to the growth of amoebae and that this property is not affected by contact with intestinal mucus quite to the same extent as in the case of emetine.

The diminution of the amoebicidal action of these drugs by contact with mucus is better seen when we compare the results of the above two experiments with those obtained by incorporating varying dilutions of the two reagents without any admixture with mucus.

Results without Admixture of Mucus.

Emetine Hydrochloride concentration in the Medium.	Bacterial Growth.	Amoebic Growth.	Conessine Sulphate concentration in the Medium.	Bacterial Growth.	Amoebic Growth.	Control.
0.1 %	+	0	0.1 %	+	0	Bacterial growth } ++ Amoebic growth } ++
0.01 %	++	0	0.01 %	+	0	
0.001 %	++	0	0.001 %	++	0	
0.0001 %	++	0	0.0001 %	++	0	
0.00001 %	++	++	0.00001 %	++	++	

From these experiments it is evident that conessine is, if not actually amoebicidal, at any rate capable of inhibiting the growth of free-living amoebae when planted on media containing even a concentration of 1 in 1 million, and that this property is equal to that of emetine. Further, it is clear that the inhibitory action of these drugs on the growth of the amoebae is not due primarily to a deprivation of food supply of the amoebae by the inhibition of bacterial growth, for it is shown that the amoebic growth is affected before there is any change in the amount of bacterial growth. Another point that is manifest is that the inhibitory action of both emetine and conessine upon the growth of the amoebae is not affected by heat, for the media containing these alkaloids had been subjected to a temperature of 115° C. for twenty minutes in the autoclave. It might be argued that this strain of free-living amoebae was very sensitive to the action of alkaloids in general, and in order to see whether this was the case the inhibitory action of conessine was compared with that of quinine bihydrochloride, with the following result.

Comparison of Conessine and Quinine.

	Conessine Sulphate.				Quinine Bihydrochloride.			
	0.1 %	0.01 %	0.001 %	0.0001 %	0.1 %	0.01 %	0.001 %	0.0001 %
Amoebic growth	0	0	0	++	0	++	++	++
Bacillary growth	0	+	++	++	+	++	++	++

The conditions of the test in this case were identical with those the results of which have been recorded above, with the exception that the medium in this case had a reaction of pH 7.5 and in the former cases it was pH 7.9.

It will be noticed that complete inhibition of growth when using a medium of pH 7.9 occurred in a concentration of 0.0001 per cent., whereas with a medium of pH 7.5 total inhibition does not occur until a concentration of 0.001 per cent. of conessine is reached. This is interesting in that it agrees with the finding of Acton¹⁰ that the toxicity of the cinchona alkaloids on paramoecium varies with the pH of the culture. They are much more toxic in alkaline than in acid cultures.

Mode of Action of Emetine on Amoebae.

That this cannot be looked upon as due to a direct amoebicidal action is held by Dale and Dobell, who consider that the host must in some way co-operate in the effect.

In order to see whether the serum of a patient receiving large doses of emetine had any action on free-living amoebae, the serum of a man who had received twelve daily doses of bismuth emetine iodide was allowed to interact for varying time limits up to two hours with an equal volume of a saline suspension of free-living amoebae. A control with normal serum was used. After interaction at room temperature a loopful was planted on Walker's medium, but the reading after forty-eight hours showed no difference in the amoebic growth in the case when the emetinized serum was used as compared with that when using normal serum.

Comparative Toxicity of Emetine and Conessine.

Burn (1915) states that comparatively large doses of conessine may be given subcutaneously to cats, rabbits, and guinea-pigs without any danger to life, but in every case, even when such a small dose as 10 mg. was given to guinea-pigs, there was considerable local necrosis and induration, although carried out under strictly aseptic precautions. The smallest subcutaneous dose which he found lethal to a 300 gram guinea-pig was 250 mg. This necrosis might possibly have been due to the reaction of the sample used, but when even a neutral solution was employed there was some degree of necrosis when 50 mg. was injected subcutaneously into guinea-pigs. Whether this can be obviated requires further work.

As regards the oral method of administration, one guinea-pig of 600 grams was given 1 c.cm. of a 10 per cent. solution and showed no symptoms, whereas a guinea-pig of 680 grams which received 5 c.cm. of a 10 per cent. solution died in forty-eight minutes, death being preceded by paralysis of the hind limbs. The toxicity of emetine and conessine is shown in the following observations.

Intravenous Administration.

Emetine Hydrochloride (0.1 per cent. solution):

Mouse 25 grams, 0.1 c.cm. ... No symptoms.
Mouse 25 grams, 0.3 c.cm. ... Severe symptoms; recovered.
Mouse 20 grams, 0.3 c.cm. ... Died in two minutes.

Conessine Sulphate (0.1 per cent. solution):

Mouse 27 grams, 0.4 c.cm. ... No symptoms.
Mouse 22 grams, 0.4 c.cm. ... Severe symptoms; recovered.
Mouse 22 grams, 0.45 c.cm. ... Died in about one minute.

Subcutaneous Administration.

Emetine Hydrochloride (1 per cent. solution):

Mouse 29 grams, 0.1 c.cm. ... No symptoms.
Mouse 24 grams, 0.3 c.cm. ... Died during night.

Conessine Sulphate (1 per cent. solution):

Mouse 22 grams, 0.2 c.cm. ... No symptoms.
Mouse 24 grams, 0.4 c.cm. ... Died during night.

Hence the subcutaneous M.L.D. of conessine for a mouse is approximately 3 mg., and of emetine 2 mg. The intravenous M.L.D. is 0.45 mg. and 0.3 mg. respectively, or, in other words, as far as these observations go emetine is approximately 50 per cent. more toxic than conessine.

SUMMARY.

1. Conessine, an alkaloid having the formula $\text{C}_{12}\text{H}_{20}\text{N}$, which has been isolated from several members of the family of Apocynaceae, is here shown to exert a very strong inhibitory action upon the growth of free-living amoebae; in fact, exactly equal to that of emetine.

2. Infusions of the seeds of these plants have for many years been used with marked success in cases of chronic dysentery.

3. Although when administered subcutaneously conessine produces an area of necrosis at the site of inoculation, it can yet be administered by the mouth or intravenously in suitable doses without producing symptoms.

4. It is approximately 50 per cent. less toxic than emetine.

5. A diminution of the inhibitory action on free-living amoebae of solutions of emetine and conessine which have been in contact with intestinal mucus is shown.

6. The serum of patients receiving full and repeated doses of emetine has apparently no amoebicidal action; hence it is unlikely that the presence of conessine in blood serum could be detected by its effect on amoebae.

A MODIFICATION OF THE OPERATION OF CHOLECYSTENTEROSTOMY.

BY

ANDREW FULLERTON, C.B., C.M.G., F.R.C.S.,
SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST.

WHEN a gall bladder is packed with gall stones, when its walls have lost their elasticity and contractility, are thick, leathery, opaque, and infiltrated with micro-organisms, there is very little doubt that the best procedure is to remove it. In recent years, however, the tendency has been to remove the gall bladder even when the signs of disease in its contents or walls are so slight as to require more than moderate experience in this branch of surgery for their diagnosis.

The removal of the gall bladder is now so frequent that this organ almost rivals the appendix as an object of attack. Its retention in the body may, however, be of great service to the surgeon in facilitating the drainage of the common bile duct when for any reason the flow of bile from the common duct to the duodenum is partially or completely obstructed. The most usual cause is chronic pancreatitis. To relieve the obstruction in such a case the gall bladder has been anastomosed to the stomach, the duodenum, or even to the colon. Although success has attended some of these operations there are certain objections which may be urged against them.

1. The gall bladder and its contents are infected and may remain so. This constitutes a grave danger to the health of the patient.
2. Gall stones may form, or, if they have been removed, may recur.
3. The contents of the stomach, duodenum, or colon may regurgitate into the gall bladder.

These disadvantages may be met, to a large extent, by the following procedure: The gall bladder is opened and cleared of its contents. A light clamp is placed near the neck, and the greater part of the viscus is removed. The small remaining portion is anastomosed to the duodenum, so that when the operation is completed the cystic duct opens into the duodenum without the intervention of any sac which might harbour gall stones or regurgitated intestinal contents. Just enough of the gall bladder is left to enable the anastomosis to be satisfactorily accomplished.

The following case was dealt with on these lines.

Mrs. R., aged 55, seen with Dr. William Monypeny, had suffered for ten years from attacks of pain radiating to the back. These attacks occurred at intervals of a few months. She had lost about 2st. in weight during the last five years. The last attack occurred a few days before her admission to the Royal Victoria Hospital on April 4th, 1922. On this occasion she was jaundiced for the first time.

The patient was spare but not wasted. She complained of pain and tenderness in the epigastrium; the sclerotics were yellow, the urine was bile-stained, and the stools clay-coloured. The temperature rose in the evenings to 99.2° F., and the pulse ranged from 75.

Required to ease the pain.
1922. Right rectus incision. The gall bladder adherent to the colon, its walls were thick and opaque, and gall stones could be felt in its interior. The pancreas from head to tail was firm and hard, almost suggesting growth, but the gland was not fixed to its surroundings. Chronic pancreatitis was diagnosed. The gall bladder was opened and seventy-six gall stones were removed. The common and hepatic ducts were clear. The main part of the gall bladder was removed and the stump was anastomosed to the anterior surface of the first part of the duodenum, using fine catgut for the sutures. Light clamps were used to prevent extravasation and bring the parts into apposition. The abdomen was closed without drainage.

Result.—Jaundice disappeared in a few days, the wound healed by first intention, and the patient left hospital eighteen days after operation quite well. After leaving the hospital she had a bismuth meal, and there is no evidence in the skiagram of any pouch connected with the duodenum.

In this case I was afraid to remove the gall bladder completely on account of the state of the pancreas, and the presence of jaundice, possibly due to the latter. The operation I have described solved the difficulty. Even if further thickening of the pancreas takes place the patient has a safety valve in the cystic duct, and she is, in addition, relieved of the greater part of a much diseased gall bladder.

The patient reported herself on May 29th. She is steadily regaining weight.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ERYTHEMA NODOSUM ASSOCIATED WITH ACUTE RHEUMATISM.

THE following case seems to me of interest, especially in view of a correspondence which occurred in issues of the BRITISH MEDICAL JOURNAL during November, 1921. The case shows so close an association between erythema nodosum and rheumatism as to suggest that these two conditions are manifestations of one and the same infection.

Miss T., aged 38, was first seen on April 27th, 1922, when she complained of severe pains in the legs, arms, and back, and of sore throat. Typical erythema nodosum was present on both legs and on the right arm around the elbow. The throat was very injected; the heart, except that the first sound was of very poor quality, was normal; the joints, apart from pain on movement, showed nothing abnormal. The temperature was 100.4°.

On the following day both wrists, the right knee, and right ankle were red, swollen, and acutely tender. The temperature had risen to 101°. After thirty-six hours the joints mentioned started to clear up, and the temperature to come down to 99.2°. On May 1st, however, the right elbow became acutely inflamed, and the temperature again rose to 100.4°. By May 5th the active process in the joints was at an end, and the temperature varied between 98° and 99°. At the sites of the original eruption a dull purple stain remained; the throat was normal, and the heart up to May 19th has remained free.

Large doses of salicylates were given from the onset of the illness on April 27th.

A point of some interest is that a brother of the patient suffered with chorea as a child.

Hampstead, N.W.

HUGH WETHERBEE.

RECURRENT VESICULAR ERUPTION AFTER INFLUENZA.

W. E. B., an omnibus ticket inspector, a married man of very abstemious habits, was taken ill on January 10th with intense frontal headache, aches and pains in all his limbs and joints, cold "shivers," and a high temperature. His condition was diagnosed as influenza, and a mixture containing sodium salicylate and diaphoretics was prescribed. In the ensuing week he developed a slight degree of tonsillitis, which cleared up in a few days. Otherwise he felt quite well, the influenza having lasted three days only.

From January 14th to 18th he had been having skate for his daily dinner. Other members of the family also partook of the fish, but remained quite well. He had partaken of skate on several occasions previously, but no rash ever developed subsequently. On January 19th there appeared on the anterior aspect of the left wrist a small reddish, itchy patch. This consisted of small red, raised papules about the size of a pin's head. Two days later the patch extended to the palm and fingers, and the right hand was now similarly affected, the wrist, palm, and fingers being involved. Calamine ointment was prescribed. The following day severe pains were felt on the top of the head, and the patient was of the opinion that "something was gathering under the scalp." Next morning, the hands, front and back, were very swollen and red. Intense burning and itchy sensations were felt in the affected areas, and in the course of the day small vesicles formed on the anterior aspects of the palms and wrists of both hands. A day later the vesicles ruptured and there exuded for two days a yellowish-green fluid. At the same time the skin over the inner aspects of both thighs, from the groins to the knees, was very itchy and slightly inflamed. Calamine lotion was freely applied, and the parts were covered with cotton-wool. Mist. alba, 3ss morning and evening, was prescribed.

On January 27th the patient had chicken for dinner, and three hours later an acute vesicular eruption broke out over the entire scalp, the back of the neck, and both ears. The vesicles soon broke down and discharged a yellowish-green fluid. The next day the back, the chest, and the entire abdomen were covered with reddish papules, and the itching was very considerable. The discharge from the affected areas ceased a day later, though the parts remained swollen, burning, and intensely itching. In the ensuing week good progress was made to recovery till February 5th, seven days after the previous attack. The vesicular eruption again

appeared over the same areas. Strict attention had been paid to the diet—two eggs, tapioca pudding, bread-and-butter, and tea, the fare on Sundays being the same as on week-days. On February 12th very severe neuralgia of the right side of the face and head developed. This lasted for eighteen hours, and during this period the vesicular eruption recurred as before on the head, neck, ears, and hands. The next recurrence was on February 19th, the same areas being involved. The fluid discharged on this occasion from the head and neck was roughly estimated at half a pint. On February 27th the headache and eruption returned. The neuralgia was very intense and lasted sixteen hours. Potassium bromide, grains 40, failed to give any relief. The eruption on this occasion was not so severe. The fingers were fissured and discharged a watery fluid. On March 5th the neuralgia recurred, but there was no accompanying eruption. However, the face and body assumed a peculiar yellowish colour. A mixture of arsenic and iron was prescribed and the condition cleared up in two days. The hands are still slightly swollen, and the skin on all the areas which had been affected is exfoliating.

An examination of the white blood cells gives the following percentage: Basophils 3.5, eosinophils 6.0, polymorph leucocytes 54.5, lymphocytes 36.0.

It is to be noted that there have been at intervals of six to eight days six recurrent attacks of a herpetiform character, each lasting about two days. No article in the food taken can be blamed definitely as having been the cause of the undue sensitization. Fish had been cut out of the diet from the time the first eruption occurred, as it was thought that the skate was the causative factor. The fact that the eruption was symmetrical is not in favour of herpes zoster. Therefore the only conclusion, in my opinion, is that the case is probably a toxæmia of influenzal origin.

London, N.W.

A. W. PANTON, M.B.

CANCER OF TONGUE: EXCISION OF TONGUE: CANCER OF STOMACH 34 YEARS LATER.

THE following facts are of interest as a minor contribution to the study of malignant disease:

H. T., aged 72, was under my care for several months suffering from vomiting, pain in the epigastric region on swallowing food, and loss of weight. Malignant disease of the lower end of the oesophagus or cardiac end of the stomach was diagnosed, and he was admitted to the Warrington Infirmary on May 2nd, 1922, for the operation of gastrostomy. The operation was performed next day and he died on May 11th.

A post-mortem examination was made on May 12th, and the stomach was removed. A cauliflower-like growth, about the size of a Tangerine orange, was found at the lesser curvature, near the opening of the oesophagus. There were no metastatic deposits on the liver. One small white nodule—the only one present—was excised for examination. The report of microscopical examination made by Dr. H. A. Mitchell, of the Runcorn Research Laboratory, was as follows: "Tumour, stomach.—Sections made from this specimen show the structure of an adeno-carcinoma. Nodule, liver.—Sections made from this specimen show the structure of a tuberculoma."

The interesting point about this case is that the patient's tongue was completely excised for epithelioma thirty-four years ago at the Skin and Cancer Hospital, Myrtle Street, Liverpool, by the late Dr. Stopford Taylor. Unfortunately there is no written record available at the hospital, but the secretary, Mr. W. R. Driver, informs me that the present dispenser distinctly remembers the case to be one of epithelioma, and that he was present at the operation. This statement is corroborated by the patient's relatives, who remember clearly that a piece of the tongue was first excised (presumably for microscopical examination) before the major operation was undertaken.

There was no recurrence after the first operation, and the patient lived an active and healthy life for thirty-four years until attacked by the carcinomatous growth of the stomach which ended his life. This growth had no connexion with the growth of the tongue, and was evidently of independent origin.

While epithelioma of the tongue is rare at the age of 38, yet the evidence is fairly conclusive that it was present in this case. This being so, the case goes to show that an attack of cancer cured by operation does not render a patient immune to a new and independent attack in another region of the body later on in life.

Warrington.

J. S. MANSON, M.D., D.P.H.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

ULSTER BRANCH.

A CLINICAL meeting of the Ulster Branch of the British Medical Association was held in the King Edward Memorial Hall, adjoining the hospital laboratories, of the Royal Victoria Hospital, Belfast, on June 1st, when the President, Dr. ROBERT REID, occupied the chair.

Dr. CALWELL showed the case of a young man with a vague history of *petit mal*, who had been admitted to hospital suffering from symptoms of brain pressure without localizing signs. A decompressing operation was performed with much general relief and improvement of sight; he then suddenly relapsed and became blind and developed some mental symptoms, depression, great dullness of cerebration, etc. A cystic tumour formed close to the site of operation under the scalp; this was tapped and clear cerebro-spinal fluid was obtained, and he improved—was able to get up and walk about. The cyst had formed several times, and on one occasion 177 c.cm. of fluid was obtained; his sight was fair, but there was some optic atrophy in both eyes, and a slight paresis of opposito side was less marked than before operation.

Dr. McAFEE showed two charts in Dr. Calwell's wards, one of a fatal case of small white kidney in which the blood urea gradually rose from 160 mg. of urea per 100 c.cm. of blood, to 500 mg., when the patient became comatose and died in a few days; her blood pressure also rose, but not in proportion. Although she had most extensive retinal changes and toward the end was completely blind, she remained perfectly clear in mind till shortly before onset of coma. The urea-concentration test was obtained only once as she vomited the urea; it was only 0.8 per cent. The other chart was that of a man who was admitted for Bright's disease; under treatment the albumin disappeared, the blood pressure, the urea-concentration test, and the blood urea all improved, but never quite to normal. He was retained in hospital for several weeks, and finally discharged as a case probably of incipient cirrhosis, with injunctions to report any illness.

Dr. Houstoun gave a demonstration in his laboratory of Dreyer and Ward's technique in the Wassermann test for syphilis, showing its reliability, greater sensitiveness, facility of manipulation, and the great advantage of being quantitative, giving a degree of infection from 0 upwards instead of the simple "positive" or "negative."

Dr. RANKIN showed charts illustrating the effect of treatment by salvarsan and by mercury on the Dreyer-Ward and Wassermann reactions. When the Dreyer-Ward method is graphed out, the effect of treatment is very clearly shown as a rapid reduction to normal, instead of the simple "plus" or "negative," with corresponding improvement of symptoms: some cases show a preliminary rise, giving a curve; this rise of curve is apparently not associated with increase of the symptoms.

Dr. TURKINGTON showed some fine examples of the growth of the *Bacillus tuberculosis*, and some microscopic slides; where antiformin had been used few or no bacilli were found, but where simple saline solution had been used bacilli were found in abundance.

Dr. ALFREDA BAKER gave a demonstration of Bloch's method of estimating the coagulability and retractility of the blood (vide *Lancet*, August 7th, 1920). Professor JOHNSTONE showed numerous gynaecological specimens, and Mr. MALCOLM showed several cases of spinal caries in course of treatment. Dr. J. A. SMYTH gave a demonstration of van den Bergh's test for bilirubin in serum; his results had supported the claims of the test. Dr. ROBERT MARSHALL showed a case of syringomyelia of the "Morvan's disease" type, and gave a demonstration of the various points. Dr. BOYD CAMPBELL showed different forms of the malarial parasite. Dr. J. C. ROBB showed ova of *Bilharzia haematobia*.

Mr. FULLERTON showed: (1) A series of cases of cleft palate in children successfully operated on. (2) Two cases of undescended testicle in which the testicle had been replaced in the scrotum. (3) A series of cases of tendon transplantation for deformities due to infantile paralysis. (4) A series of cases illustrating the results of operation for knock-knee, curved tibiae, and curved femora. (5) A series of cases of fracture treated by Thomas's splint. (6) A series of cases illustrating the results of excision of gunshot wounds. (7) A series of pyelograms illustrating the causes of renal pain. (8) A case

of injury to the axillary artery and vein. (9) A patient operated on for an enormous abdominal cyst. (10) A case in which the lower lip had been removed for epithelioma treated by plastic operation.

Mr. IRWIN showed specimens of loose bodies removed from knee-joint, two gall bladders removed for gall stones, a calculus from pelvis of kidney, vesical calculus and enlarged prostate removed from same patient, and a hypernephroma of kidney extending into renal vein; when the vein was slit up the growth was seen projecting into its lumen; the growth was quite soft, and small particles could easily be detached. He also showed: (1) A case of fragilitas ossium with blue sclerotics in a little girl who had had already twelve fractures. The familial nature of the affection was shown by the family tree. (2) A case of a girl with ascites without discoverable cause; the patient had been examined by several medical men, the fluid drawn off, and an exploratory laparotomy performed and an epiplolexy done.

Dr. NORMAN C. GRAHAM gave a demonstration of d'Herelle's "bactériophage" effect on cultures of bacillus Shiga, both in suspension and on plate; this demonstration excited much interest.

Professor MACILWAIN showed a series of electro-cardiograph tracings in seven cases illustrating the effect of quinidine on auricular fibrillation. One case showed the return to normal rhythm without improvement in the patient's general condition; in another, tachycardia of nodal type occurred associated with considerable precordial discomfort; the tachycardia disappeared within thirty-six hours of stopping the drug.

Reports of Societies.

MEASURES AGAINST TUBERCULOSIS.

At a meeting of the Edinburgh Medico-Chirurgical Society held on June 7th, with the President, Sir ROBERT PHILIP, in the chair, Professor A. CALMETTE, Pasteur Institute of Paris, delivered an address, as we briefly noted last week, on the protection of mankind against tuberculosis.

Professor Calmette said that after his demonstration of the specific character of the tuberculous virus and its inoculability to different animal species, Villemin, finding it difficult to transmit tuberculosis to the dog, the cat, and the sheep, was the first to raise the question whether animals existed which were non-sensitive to this disease. Later, after the discovery of the tubercle bacillus by Koch, it was found that almost all mammals could be artificially infected, but that a small number of species had the grim privilege of contracting tuberculosis spontaneously, and that others—for example, certain rodents in the Sahara Desert and in the steppes of Southern Russia—were so highly resistant as to be immune even to artificial inoculation. These non-tuberculizable animals were thus naturally resistant. Tubercle bacilli remained within their tissues as inoffensive foreign bodies, being eliminated gradually by way of the natural discharge of cellular waste, although for months they retained their vitality and virulence, and could be traced in the neighbourhood of the point of inoculation; for they were perfectly capable of tuberculizing other susceptible animals such as the guinea-pig. It was the establishment of a tolerance of this kind which must be our aim in the production of artificial immunization. It would be vain to hope to be able in the case of animals susceptible to tuberculous infection to confer the power of digesting tubercle bacilli when animals naturally resistant to the disease cannot do so. The problem, therefore, was how to render the leucocytes and the endothelial cells of the vessels—which enclose the tubercle bacilli but are unable to digest them—non-sensitive to the poisons which the bacilli contain and secrete so that the organism may tolerate them as it can tolerate in most of its tissues the presence of a number of inoffensive foreign bodies such as particles of silica or carbon. When Koch prepared his first tuberculin he believed that this purpose had been attained. Those who were then doing laboratory work would never forget the immense enthusiasm aroused by the announcement nor the cruel disillusionment which followed. A specific cure for tuberculosis had not been found, but Koch had observed a fact of capital importance—namely, that tubercle bacilli, whether living or killed by heat, act very differently according as they are introduced subcutaneously into a tuberculous guinea-pig or into a healthy

guinea-pig. While in the case of the healthy guinea-pig they gave rise only after several days to the formation of a nodule which discharges externally, causing an ulcer which may continue till the death of the animal and which led to intense swelling of the neighbouring lymphatic glands, a similar inoculation in the case of the tuberculous guinea-pig produced a small abscess which quickly burst and discharged and cicatrized without swelling of the neighbouring glands. This "phenomenon of Koch," the importance of which from the point of view of immunity to tuberculosis had apparently escaped Koch's attention, afforded evidence of the intolerance of the tuberculized animal to fresh infection. Experiments showed that this intolerance became more and more marked and revealed itself by an effort to expel the bacilli which was more intense and more rapid with each fresh reinfection.

As regards humans, continued Professor Calmette, it was in earliest infancy that household contagion, which was almost inevitable for infants born of phthisical mothers, was most serious and most generally fatal, because it was massive and repeated day by day. After the third year such infection, usually occasioned then by accidental exposure or intermittent contact, was less formidable and produced more often glandular lesions of a benign character. It seemed that for man, as for animals which develop tuberculosis spontaneously, one early and slight inoculation was desirable provided it was not followed by further repeated massive infections; every subject infected in childhood by a very feeble dose of bacilli was rendered less likely to contract acute miliary tuberculosis. Should the individual be exposed later to repeated or massive contagion he would show his intolerance to reinfection by developing chronic tuberculosis or cold abscesses or other local tuberculous lesions, which suppurate readily. Slight infections not repeated tended to be benign in children, while, contrariwise, they were grave in the adult who had remained virgin soil in respect of bacillary implantation. This was why country people who after adolescence had migrated to the city developed so often a serious type of tuberculosis, and also why negro races from Central Africa were so sensitive when transferred to a European country.

Professor Calmette then went on to speak of the difficulties and disappointments associated with attempts to produce artificial immunity, discussing briefly, in this connexion, the work of Behring, Stanley Griffith, Theobald Smith, and Forran. It was difficult to prosecute these attempts at anti-tuberculous vaccination in laboratories and in countries where bacillary infection was so widespread that a given animal could not certainly be protected from accidental contagion. It would be necessary to make the attempt in a country where there were no men, no cattle, nor other tuberculous agents. He proposed the creation of a centre of research in a position as isolated as possible, preferably on the west coast of Africa in the great belts of forest inhabited by large anthropoid apes, especially the chimpanzee. In such a laboratory one could keep the vaccinated animals in a state of semi-liberty, securing for them nourishment and conditions of climate in conformity with their needs. After a more or less prolonged interval it would be possible to test on the spot their resistance to artificial infection, or they might be transferred to Europe, where they would be exposed to natural contagion which so cruelly affected their congeners in menageries. It was meantime our duty to pursue investigations which tended to produce in young animals and in children that particular state of intolerance to reinfection which might result from the early implantation in the organism of a small number of slightly virulent bacilli, or by bacilli which do not produce tuberculous lesions.

The essential aim, Professor Calmette concluded, was not, as some had supposed, exclusion of the possibility of bacillary contagion, but rather the realization of contagion in all human beings, as soon as possible after birth, in a form which was inoffensive and protective for a sufficiently long time against serious infection. The establishment of such resistance on the part of infants ought then to become the immediate object of our constant endeavour. The child must be immunized from his earliest age, first, because in infancy he was most exposed, and further because it was relatively easy to shield him from repeated and massive contagion which irremediably imperilled his life. The practical conclusion which emerged from our present-day knowledge was that efforts should principally be directed towards the protection of childhood. That protection was realized most effectively in the first place by removing the infants of phthisical mothers separately to healthy households in the country, thus ensuring their protection from

infective contact during the first two years of life; next, by the removal of families or larger groups of children from 3 to 13 or 14 to sanitary conditions above suspicion; and, finally, by the constant surveillance of schools, of apprentice workshops, and food supplies, such as milk, which may contain or carry tubercle bacilli. One might hope that later, when knowledge had advanced still farther, it would be possible to confer on babies from the moment of their appearance into the world, through the ingestion of, or inoculation with, a certain number of living but non-tuberculous bacilli, the capacity to resist accidental virulent infection. The whole world awaited anxiously such a realization.

Professor JAMES RITCHIE said that tuberculosis was one of a group of diseases in which the explanation of immunity and of recovery was at present not clear. He thought that meantime the idea of instituting immunity by early inoculation should be confined strictly to the medical profession; for the public to imagine that, with this end in view, the consumption of tuberculous milk was justifiable would be very harmful. He thought the geographical and racial distribution of tuberculosis had received insufficient attention.

The President, Professor LORRAIN SMITH, and Professor GULLAND also contributed remarks and criticisms.

RHEUMATOID ARTHRITIS AND ITS TREATMENT.

A MEETING of the West London Medico-Chirurgical Society was held on Friday, June 2nd, with the President, Sir GEORGE LENTHAL CHEATLE, in the chair, when a paper on rheumatoid arthritis was read by Dr. LEONARD DOBSON.

Dr. Dobson began by defining the disease as an acute or chronic disease of the joints, of infective toxic or septic origin, due to specific infection by micro-organisms, mostly of low virulence. The disease commenced usually about middle age; in women the menopause being a favourable time of occurrence. The general picture of a case gave many evidences of auto-toxaemia. Usually there was a local focus of infection. Diseased tonsils, oral sepsis, pyorrhoea, nasal catarrh, intestinal derangements, uterine discharges, and chronic constipation should be carefully searched for. In auto-toxaemia of gastro-intestinal origin, stasis and constipation were important factors; indican and indol in the urine gave evidence of such infection. The tubercle bacillus, gonococcus, and *Spirochaeta pallida* were causes of infection by micro-organisms of low virulence, producing varying symptoms of arthritis. A condition of impaired health and disturbance of the gastro-intestinal functions might pave the way and set up the first stage of a rheumatoid arthritis. Regarding symptoms, in the acute form of the disease pain was a marked feature. Many joints were usually involved and the patients were generally young women and sometimes children. The subacute and chronic forms were by far the most common. The pain in these cases was not so severe, and only one or two joints were at first involved. The progress of such cases was usually one of alternate improvement and relapse—deformities of the joints appeared, pain was more severe, the patients gradually becoming more and more helpless with increasing deformities of the joints affected.

In considering treatment, Dr. Dobson emphasized the necessity of careful search for local foci of infection. He deprecated the existing fashion or craze for wholesale extraction of teeth whenever there was the slightest trace of pyorrhoea or sepsis of the gums. He felt sure that in a large number of cases this was utterly wrong. He considered that pyorrhoea was often a secondary result and not a primary cause of general septic infection. Autogenous vaccine was useful when any local source of infection could be found. Bacteriological examination of the urine and faeces should be made in cases where a local focus could not be discovered. He advocated the treatment by prolonged blistering of the spine, or by thermo-cautery as a substitute. Constipation and stasis must be eradicated. For enteroptosis, of frequent occurrence in advanced middle age, measures must be taken for giving abdominal support by means, in men, of a Curtis belt, or in women of a supporting corset. For constipation he advised 1/2 oz. of liquid paraffin before or after breakfast; at 10 a.m. 1/2 to 1 c.c.m. of pituitrin intramuscularly, and twenty minutes later a Plombières douche. Salicylates were of little or no value. Pain should be treated, as it was usually the principal symptom calling for relief. An emulsion of sulphur in olive oil, intramuscularly, was said to be very beneficial when the joints were swollen and painful. Quinine

and guaiacum were useful after improvement had set in, and he believed in giving calcium in some form, combined with tonics, fats, and a generous diet. Regarding local treatment he advocated radiant heat or hot air baths, which gave great relief in many cases, suitable fixation of the limb by means of splints being made as an aim to restore the damaged joint to a state of functional efficiency. For the relief of pain, Bier's rubber bandages might be used. Schnee baths were of great value. For painful joints, salicylate ionization might be tried. Faradization of wasted muscles should invariably be carried out during convalescence. The patient should be prepared to undergo a course of continuous treatment for three or four months, which, if properly carried out, would ensure a considerable measure of success and rheumatoid arthritis would not seem to be the hopeless disease to treat that it appeared to many to be, at present.

In the discussion that followed, Sir WILLIAM WILCOX was convinced of the infective nature of the condition. He was a strong believer in the Plombières treatment and thought that good results sometimes followed the administration of sour milk.

Dr. SEYMOUR TAYLOR agreed as to septic contamination of the blood by micro-organisms and was convinced that more than one micro-organism was capable of producing the disease. He believed in the Plombières treatment and in the value of blistering.

Dr. KNYVETT GORDON spoke of the lesion in rheumatoid arthritis as a chronic interstitial fibrosis caused in the majority of cases by a slowly acting bacterial infection. Vaccine therapy was indicated and the serum-resisting test should be employed to determine the organisms that were pathogenic. A blood examination was useful, a bacillary infection being characterized by leucopenia with relative lymphocytosis and a coccal infection by leucocytosis with relative polymorph predominance.

Mr. McADAM ECCLES spoke of the condition of false ankylosis by extra-articular fibrosis and the surgical aspect of such cases.

Other speakers included Drs. RICKARD LLOYD and ERIC DOBSON and Mr. BALDWIN.

CONSERVATIVE LABOUR INDUCTION.

A MEETING of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine was held on June 1st, when the President, Professor HENRY BRIGGS, read a paper on conservative labour induction.

He said that in the treatment of labour in the minor degrees of pelvic contraction or of the equivalent foetal oversize, the first place belonged to labour induction, and in practice there could be no denial of its outstanding merit as the nearest approach to the normal labour. The obstetrical meridian was occupied by well-housed and well-managed normal labour. On its borderland, within the above group, arose exacting appeals to higher obstetrics, to be gradually or promptly fulfilled prior to the adoption or exclusion of induction. A half-hearted faith in clinical investigation sheltered under Caesarean section, while a whole-hearted faith resolutely sought and gathered diagnostic equipment for a more accurate differentiation, and limited Caesarean section. Notoriously disturbing elements in labour prognosis were the uncertainties in the behaviour of a flat pelvis of minor degree, and the surprises they had so far impressed upon clinical discernment and labour management. The generally contracted pelvis, or its equivalent in minor degrees, was a formidable antagonist during full-term labour. It intensified the head-moulding and the expelling forces, increased the suffering, and demonstrated the invaluable benefits of opium against a too hasty or too early forceps application, with the risk of the object lesson of forceps failure, an easy and rare craniotomy, or a conservative Caesarean section. In the interests of the child the practice of induction earlier than the thirty-sixth week was to be discouraged, if possible, as the speaker had said in 1893. Full-term Caesarean section then promised the brighter future it had since shown, and had on two occasions been adopted by himself in the treatment of labour in the major degrees of pelvic contraction. The foetus in the thirty-sixth week or later had reached a period of eligible viability; this became in his practice the workable criterion. The selection of induction—the persistent crux of obstetricians—led beyond an isolated polyvinyl or the latest ruling on the pelvic conjugate. It raised the accoucheur's bimannual estimate of the relative size of the foetal head and the pelvis

to a responsible auto-natal assessment to which average fingers and thumbs had generally proved equal, without or with a judicial allowance for adaptability and compensation within the concerned anatomical structures and physiological functions.

Dr. HERBERT SPENCER said that the paper dealt with induction of labour: he pointed this out as many were apt to confuse this with induction of premature labour, the foetal mortality of which was much higher than when induction was carried out at, near, or beyond term. He had in thirty-five years only known one patient die of infection after induction of premature labour: the case was after a very prolonged labour and the occurrence of high fever and a rigor, operated on by Caesarean section, and died of peritonitis—the only fatal case he had had after Caesarean section for contracted pelvis. He had induced labour in a very large number of cases; one woman had twelve living children, all of which had been induced by the speaker. He agreed with the President that Caesarean section was done too often.

Dr. ANDREWS said that there were two factors which led to the idea that induction of premature labour should be given up. One was that it was often performed too early, on account of the ancient heresy, which was still deeply rooted not only among patients, but also among some medical men, that a seven months' child might live, while an eight months' child had less chance of living. The other factor was that still more patience was necessary in delivery of a premature child than in labour at term, and those who hastened the delivery of a premature infant by use of the forceps were usually disappointed with the result. If induction of premature labour was done at the right time, and the delivery conducted with patience, the results were excellent.

Mr. GORDON LUKER showed a specimen of a uterus removed with a solid ovarian tumour for obstructed labour. The tumour lay in Douglas's pouch and was pushed down into the pelvis by the foetal head. It measured 19 by 9 by 4.5 cm. Caesarean section was decided upon, because the foetus was about fifteen days post-mature and large, its heart beats were becoming more rapid, and because of the mother's age. If the child was born alive it was decided to remove the uterus because of probable infection. The child was extracted in the usual way alive, and the uterus, left tube, and left solid ovarian tumour were removed; a small portion of the cervix was left behind. The patient made an uninterrupted recovery. Histological examination of the tumour showed it to be a solid polygonal-celled scirrhous carcinoma of the ovary.

Dr. HERBERT SPENCER thought the right treatment had been carried out in removing the uterus; he would, however, have preferred total hysterectomy, as it removed the cervix, which was torn and the most likely part to be infected.

Dr. ANDREWS said that if Mr. Luker expected adverse criticism of his treatment of this case he would probably be disappointed. The case did not come into the ordinary category of labour complicated by an ovarian tumour, in which Caesarean section was to be deprecated. The reasons given by Mr. Luker for the course which he adopted—namely, the age of the patient, and the probability of infection during the attempt at delivery by the forceps—would satisfy most people that Mr. Luker was justified in performing the operation of Caesarean hysterectomy.

Mr. GORDON LUKER also read a short communication on carcinoma of the cervix following gonorrhoea cervicitis. He reported the case of a woman, aged 28, the mother of two children, who had a carcinoma of the cervix removed by him. The patient had had a discharge, in which gonococci were found five months previously, and was treated for gonorrhoea with local applications of silver nitrate solution from August until November, 1921, when she was referred to Mr. Luker on account of polypoid warts. He found irregular ulceration of the external os: the edge was undermined and bluish. He decided on partial amputation of the cervix and in doing this found the tissues of the cervix were friable. Examination of the tissue removed showed squamous-celled carcinoma, with much inflammation. The uterus was removed successfully by Wertheim's method. Mr. Luker said that the case seemed to support the theory that cancer might be caused by irritation.

Dr. ARTHUR GILES thought the view that the carcinoma had been brought about by the gonorrhoea or the treatment adopted would be difficult to prove or maintain. He pointed out how rare carcinoma of the cervix was and how common gonorrhoea was in nulliparae. If a causal relation were established carcinoma of the cervix would not be expected to be almost unknown in nulliparae.

Dr. HERBERT SPENCER had seen only two cases of cancer of the cervix and vagina in cases of proclivita. He had published his opinion that there was probably a close connexion between venereal diseases and cancer of the cervix. Mr. Luker's case seemed to be an undoubted squamous-celled carcinoma, but papillomatous growths occurred which closely resembled carcinoma unless the sections were made with great care.

Rebichus:

INFLUENZA.

THE volume edited by Dr. CROOKSHANK¹ cannot fail to interest all students of epidemiology, while its clearly written clinical articles will be of service to practitioners. The first five essays are by the editor and entitled, "Method and Thought," "First Principles of Epidemiology," "Some Historical Conceptions of Influenza," "The History of Epidemic Encephalomyelitis in Relation to Influenza." Dr. Hamer then reviews the phases of influenza in the light of historical and general epidemiological knowledge. Dr. Dwight Lewis of New Haven, Conn., contributes a too brief paper which describes from his own experience and in modern nomenclature the change of a reigning epidemic constitution. In his words: "the various waves of the so-called pandemic of influenza were caused by consecutive and increasing prevalences of correlated diseases due to the activation of carriers of the organisms of these diseases, whether by the influenza bacillus or by the streptococcus." Dr. Robert Donaldson follows with a long and fully documented essay on the bacteriology of influenza; his conclusions are perhaps more emphatic than, but very similar to, those expressed by Sir Frederick Andrews in his contribution to the report issued by the Ministry of Health. Dr. Adolphe Abrahams contributes an article on the general clinical features and treatment of influenza, Dr. Jelliffe writes on the nervous syndromes, Dr. McHoul deals with ocular affections, while the general surgical, otorhinological, and gynaecological aspects are reviewed by Mr. Sidney Boyd, Dr. Lawson White, and Dr. Aleck Bourne respectively. Dr. Haldin Davis briefly discusses the skin lesions of influenza, and the volume concludes with an essay by the editor on the theory of influenza.

No disrespect to Dr. Crookshank's very efficient collaborators is implied by the remark that the editor's contributions to the volume will probably attract more attention than theirs, because Dr. Crookshank is more deliberately provocative than are his associates. The discussion he provokes is indeed worth provoking, and, within the limits of a review, we can do no more than note some points suggested by a perusal of the volume. To Dr. Crookshank, as to Charles Darwin, the canon "*Natura non facit saltum*" is of fundamental importance. "Why," said Darwin, "should not Nature take a sudden leap from structure to structure? On the theory of natural selection, we can clearly understand why she should not; for natural selection acts only by taking advantage of slight successive variations; she can never take a great and sudden leap, but must advance by short and sure, though slow steps." Dr. Crookshank sees in the chronological development of epidemics through the ages an orderly process; he is scornful of those who discover "new diseases" and take no heed of historical inquiries. Dr. Crookshank, as one would expect the secretary of the Historical Section of the Royal Society of Medicine to be, is an enthusiast for historical research. Yet we cannot escape an uncomfortable feeling that, with all his learning, dialectical skill, and eloquence, he has not a very secure command of the historical method. The primary need of an historian is, we think, the power to understand points of view possibly very repugnant to him, an ability to see the other side of a case, and to state that other side well. Dr. Crookshank seems to have very little of this natural gift. The bacteriologist who asserts that such or such an organism is the "cause" of such or such "new" disease may neither be so ignorant nor so foolish as Dr. Crookshank seems to imply, nor in any great need of the editor's homilies on realism. The epidemiological importance of modern bacteriological work on the typhoid and paratyphoid groups would not be in the least diminished if it could be shown that paratyphoid flourished at Thasos; because a man never quotes Hippocrates or Sydenham, it

¹ *Influenza: Essays by Several Authors*. Edited by F. G. Crookshank. M. D. Lond., F.R.C.P. London: W. Heinemann. 1922. (Roy. Soc. pp. xii + 523. 7s. net.)

does not follow that he despises them. The reader gets a little weary of the reiteration "hic morbus non est novus," and wonders whether the alleged want of novelty of the subject-matter in the least diminishes the value of the bacteriologists' researches.

Even when Dr. Crookshank is criticizing purely epidemiological work, his failure to understand the point of view of those from whom he differs is often remarkable. This appears frequently in his criticism of the Ministry of Health's Report, and sometimes betrays him into definite error. Thus he asserts that "in this Report, the general idea of an epidemic constitution, and the specific idea of an influenzal constitution put forward during the past few years by Dr. Hamer and by the present writer, are implicitly recognized, though without express reference; and it would be affectation to assume that the writers of the Report were not aware of our views when penning their remarks." As three of Dr. Hamer's papers are cited in the second footnote on page 6 of the Report, and a recent paper of Dr. Crookshank's in the footnote on page 17, one wonders what definition of "express reference" is favoured by the roally philosophical epidemiologist—as distinct from "bureaucratic investigators," "office epidemiologists," and similar unlearned persons. Another instance of inaccuracy is to characterize certain rather speculative observations in the tenth chapter of the Ministry's Report as the "official theory," although in the first paragraph of the chapter the clear statement is made that it "is intended not to expound any official theory, but to suggest to other epidemiologists trains of thought the pursuit of which may lead to the attainment of important truths, and will at least tend to a clarification of ideas."

An example, not, like these, of failure to be accurate, but of grave misunderstanding, is afforded by Dr. Crookshank's denunciation of the remark that the "recorded history of an epoch which came to an end in December, 1889, in no way prepared us for the subsequent events." What the writers of the Report had in mind, as the pages following the sentence pilloried by Dr. Crookshank clearly show, was the high "endemic" level and rapid "epidemic" fluctuations of what certifying practitioners called influenza after 1889. In fact the account is little more than a documented amplification of Dr. Charles Creighton's remarks. Dr. Creighton wrote: "That which chiefly distinguishes the influenza of the end of the nineteenth century from all other invasions of the disease is the revival of the epidemic in three successive seasons, the first recurrence being more fatal than the original outbreak, and the second recurrence more fatal (in London at least) than the first." He added that the closest scrutiny of the old records discovered no such recurrence and concluded that "history does not appear to supply a parallel case to the four successive influenzas in the period 1889-94, unless we count the seasonal epidemic agues of former 'constitutions' as equivalent to influenzas for the purpose of making out a series."

Those epidemiologists who decline to believe that old medical press cuttings throw any light upon the statistical peculiarities of the post-1889 epoch may be quite wrong, but the case they present is disposed of neither by witticisms ("What is not recorded, or is not known to be recorded, does not officially happen") nor even by extracts from the *BRITISH MEDICAL JOURNAL*. These are in some sense trivial blemishes, weaknesses of manner rather than matter. But the manner of an historian is of particular importance. The bacteriologist can perhaps afford to be petulant; the evidence upon which he relies can be rapidly tested; the most vituperative statistician publishes evidence which may be analysed by his opponent without excessive expenditure of time and labour. But few have the leisure to verify the accuracy of an historical monograph, and the ordinary reader, if he finds that immediately accessible documents are misrepresented, is apt to look with suspicion on what is predicated of less accessible records.

Dr. Crookshank, we gather, believes that had our profession been properly trained in historical method the events of 1918 would not have come as a surprise, and mentions that he himself publicly predicted that 1918 would be a year of pestilence. We are not quite sure to what extent this claim is made—whether Dr. Crookshank only means that the quality of the epidemiological events of 1918 was predictable, and in fact predicted by himself, or whether he holds that a scholarly use of historical records enabled him to foresee that 1918-19 would be not merely one of the "influenza" years, but actually the greatest year of mortal pestilence since 1348-49. If, as we are inclined to think, the

claim is qualitative rather than quantitative, it appears to us that Dr. Crookshank has made out a good case in behalf of his contention; and that he has done so in a service more than counterbalancing the faults which, in our opinion, mar his exposition. We do not think, however, that the scale of an approaching visitation can be predicted without a closer co-ordination of our means of information, and the constructive proposals contained in the essay in the earlier part of the volume—substantially a reprint of a paper Dr. Crookshank read to the Epidemiological Section of the Royal Society of Medicine in 1920—deserve attention and elaboration. We shall look forward to Dr. Crookshank's further development of this side of his thought.

TREATMENT OF CONGENITAL SYPHILIS.

MM. G. LACAPÈRE and P. VALLERY-RADOT have written a small book² on the treatment of congenital syphilis. The treatment of syphilis, congenital or acquired, has become complicated in recent years by the introduction of the arsenical compounds, heralded by salvarsan, and the first half of the essay has wisely been devoted to an examination of the various medicinal substances employed in modern treatment. The three great chemical agents are mercury, arsenic, and potassium iodide. In a clear, methodical way the authors take each of these in turn; describe the various preparations and compounds used, and the various methods of administration; and assess the therapeutic value and drawbacks of each. For young infants they regard inunction of mercury as the best as well as the most convenient way of applying this drug; for older children, their choice is more hesitating, with perhaps a preference for mercury binioidide, or the benzoate salt in subcutaneous or intramuscular injections, but they also employ mercury by the mouth, while not seldom using mercurial inunction also. With regard to the arsenical compounds, they approve of three—salvarsan, neosalvarsan, and sulpharsenol. The first they consider the most efficient, but also much the most dangerous; their usual practice seems to be to use neosalvarsan if the condition of the child will permit it, but if not to use the feebler but very safe sulpharsenol. They reserve the use of potassium iodide for the late lesions of the skin, bones, and nervous system. They regard mercury and arsenic as the two essential agents in the treatment, the arsenical compounds having the more immediate and vigorous action, and the mercury following up and completing the cure.

Having described the weapons of war, the authors in the second section give an account of the battle, or rather of the long campaign. For them the treatment of a case of congenital syphilis falls into three stages: "traitement d'urgence," "traitement de fond," "traitement de sécrétité." These phrases may be loosely translated as the treatment of the acute manifestations, the radical treatment, and the insurance against relapses and late nervous lesions. As a general rule they advise that these three stages should cover a period of four years, with interposed periods of rest. The method of attack in the first stage varies according to the age of the child and the state of the disease, and is separately described for the newborn infant, for the baby a few weeks old, and for the older child. It is worth noting that, although arsenic is looked upon as the most powerful weapon in the first stage, a preliminary course of mercury is always recommended, especially in young and feeble infants with florid syphilis.

Little is said about diagnosis, which lies outside the scope of the book, and the account of the clinical features of the disease is so imperfect that it might have been omitted. Apart from that, the complicated subject of syphilis is dealt with in a clear and fairly thorough condensed way. A few case histories are included; more would have increased the value and interest of the book.

CAUSE AND TREATMENT OF DIABETES.

ALTHOUGH Colonel WATERS's book, *Diabetes in the Tropics*,³ is written with special reference to the disease as it occurs in tropical countries, there is nothing in it which cannot be most profitably read by those interested in diabetes in any climate.

² *Traitement de la Syphilis Héritaire et de la Syphilis Infantile Acquisée*. Par G. Lacapère et Pierre Vallery-Radot. Paris: A. Maloine et Fils. 1922. (Cr. 8vo, pp. 248. Fr. 10.)

³ *Diabetes, its Cause and Treatment; with Special Reference to the Tropics*. By E. Waters, M.D. Edin., M.R.C.P. Lond. 2nd edition. London: Thacker, Spink, and Co. 1922. (Cr. 8vo, pp. xii + 276. Rs. 10.)

Apart from the fact that the disease is commoner amongst the natives of India, we can see very little to distinguish tropical diabetes from that of temperate climates. An officer serving in India has over his home-staying brethren the advantage that he sees a great many more cases than anyone at home can do.

Here and there we may be puzzled by the strange articles of food mentioned, though most of us became familiarized during the war with "dal" and "ghri" as part of the rations of the Indian troops and labour companies who served with us on the Western front. Allowing for these minor differences, we can recommend this book as one of the completest and handiest guides to the study and treatment of diabetes. The author is under no small obligation to the magnificent researches of Lieut.-Colonel McCay and his collaborators. The method of investigation of cases is admirably described, food values and diet tables are excellently set out, and the details of treatment are clear and easy to follow.

We do not know where the book is on sale in this country, but if it is not readily obtainable here it ought to be.

NOTES ON BOOKS.

Taschenbuch der Therapie,⁴ edited by Dr. M. T. SCHNIRER, is a little book which appears to have achieved popularity in Germany, as it is said to be in its eighteenth edition. Under the headings of the different diseases it gives short summaries of methods of treatment, and it then proceeds to indicate the uses and doses of a large variety of drugs arranged in alphabetical order. Short notes on modern therapeutic methods are given, and there is an account of the different German spas and of the waters found there. The book does not on the whole compare very favourably with similar British publications, as most of the summaries are too short to be of much value.

A new edition of the *Michelin Guide to Great Britain*⁵ has been issued. It is the most practical guide for the tourist with which we are acquainted, as it contains at a glance the distance from place to place and gives useful indications as to the choice of routes and hotels. One of the good features of the Guide, and the same is true of the companion volume for France, is that it provides plans of a large number of towns, and everyone knows that it is more difficult to get through half a mile of a town than fifty miles of country. We are glad to observe that in this edition maps showing the main roads have been restored, the collection forming an atlas of thirty pages in colours.

we believe, be obtained at bookstalls.

THE "MENINGIOMAS."

CAVENDISH LECTURE BY PROFESSOR HARVEY CUSHING.

THE Cavendish Lecture of the West London Medico-Chirurgical Society was delivered on June 13th at Kensington Town Hall by Professor HARVEY CUSHING, who took for his subject "Dural endotheliomas," to which he gave the new name of "meningiomas." Sir LENTHALL CHEATLE presided over a large and distinguished gathering.

Professor HARVEY CUSHING said that the group of surgeons (of whom he was one) whose inclinations carried them into neurology felt the need of fresh critical inquiry in many directions. Such information as they had acquired already had come to them falteringly, although enough was now known to enable them to localize and interpret many forms of intracranial disease. It was to a particular variety of intracranial tumour that he wished to call attention, and he wanted also to give it a new name. Designations were useful only in so far as they conjured up a definite picture in the mind, and presently with growing knowledge they outlived their usefulness and had to be superseded. He took an illustration in point from the work of the man after whom that lecture was named. In 1766 Cavendish submitted a paper to the Royal Society on "Faccitious airs," and dealt with an hypothetical substance called "phlogiston," which was supposed to account for the phenomena of combustion. Later Priestley spoke of "inflammable air," but during the last century and a half the philosopher had become the scientist, "phlogiston" was forgotten, and "inflammable air" was a term which had lapsed into disuse. It was possible that before another century the

apparently stable term "hydrogen" would also disappear, and give place to something more definitive.

The tumours under consideration had masqueraded under many guises. Cruveilhier designated them "cauceros tumours of the meninges," thereby reflecting the pathology of his day, but such terms could not survive the advent of the morbid anatomist armed with microscope and staining reagents. In 1854 Paget confessed his inability satisfactorily to classify the large group of tumours which were less malignant than cancer; he suggested the term "marrow-like tumours," and another term suggested at this period was "fibroblastic tumour." But these names were descriptive merely of degenerative processes. The word "epithelioma" was favoured by some French writers, but was brushed aside by the great authority, Rudolf Virchow, who described the tumours in question as sarcomas of the dura mater. In spite of the tendency of these tumours to invade and absorb bone, it came to be recognized that they were benign lesions, in which case the term "sarcoma" had to be qualified, and later, however qualified, failed to survive. The term "endothelioma" was introduced in Italy, and made its way into other countries, and for many years pathologists had vied with one another in modifying the term "endothelioma" and extending it to a wide range of tumours with such hair-splitting refinements as to produce chaos. When there was such a multiplicity of designations it was well to attempt to rescind and reassemble these growths under a simple caption. It seemed probable that, though attached to the dura, these growths did not arise from the membrane proper, but from the arachnoid, and therefore they should not be called "dural endotheliomas." A more correct appellation would be "arachnoidal mesotheliomas," but that was too clumsy for use, and he thought it better to accept a designation which was non-committal; hence he suggested the term "meningiomas."

These tumours had favoured sites of origin, and although they might differ considerably in their histological picture they were, as a rule, easily recognizable, not only in their gross appearance, but because they were so intimately incorporated at their source with the dura that they appeared to have a dural origin. The time had long gone by when it could be hoped to advance the knowledge of intracranial tumours to any great extent by considering them as a whole. Even in their mechanical and pressure effects they differed widely, and, so far as these meningiomas were concerned, it was notably true that they might attain a huge size without giving rise to any of the so-called cardinal symptoms of tumour, such as headaches. Intracranial tumours were so protean in form, and showed such varied clinical pictures, that the only hope for progress was to partialize on certain groups. There were three ways of treating the material available: by concentrating on tumours of certain pathogenic types whatever their situation, by studying tumours of all types in a given situation, or, best of all, by restricting attention to tumours of a single type in a given situation. That evening he was compelled to pursue the first of these methods and to study the meningiomas as a whole.

The series of intracranial tumour cases which had been compiled by himself and his colleagues had been classified as tumours verified, unverified (but in which the diagnosis was practically certain), and suspect (that is, in which the diagnosis of tumour was presumptive, and its justification remained in some doubt). Out of a series of 751 verified intracranial tumours, 314 (41 per cent.) were gliomas, 159 (21 per cent.) adenomas, including pituitary tumours, and 85 (11 per cent.) meningiomas. The meningiomas, therefore, had a ratio of rather more than one to four to the gliomas or brain tumours proper. Nothing like a complete analysis of these 85 cases was possible within the limits of a single address, and he could only touch upon them in general terms from the point of view of their source and site of predilection.

Professor Cushing then gave descriptions illustrated by lantern slides of a number of cases. His first case, which dated to 1911, was of a large meningeal endothelioma of the right hemisphere, with a point of attachment in the parasphenoidal (longitudinal) sinus region. Its weight was about 130 grams, but this was not exceptional, and he showed later cases in which the weight was over 200 grams, and in one case as much as 246 grams. These tumours might be of very large size without giving any localizable symptoms. In their early work he and his colleagues set out to examine the meninges in all tumour cases, and to study the villi and the endothelial cell nests, also the cerebro-spinal circulation, without realizing that they had been forestalled by Cleland of

Glasgow and others in the suggestion that these tumours were related to the arachnoidal elements rather than to the dural. One thing to be noted was that the villi and cell nests were very difficult to find in the young. They became much more pronounced and numerous in the later decades of life. These tumours were tumours of the adult.

The function of the villi in the tumour formation was vitally important. Experimentally it had been shown that these cells were capable of considerable phagocytic action, and that was the reason why they showed a much greater development in later than in earlier life; they were increasingly called upon to act as phagocytic elements in removing debris from the villi. The tumours arose from these endothelial cell nests of the arachnoidal region; it was only in appearance that they were related to the dura. The villi which they tended to surround projected chiefly into the sinus. The usual place for the tumours to develop was underneath the longitudinal sinus, where villi abounded, and became in later life greatly hypertrophied. Trauma played an important rôle in the onset of these cases; quite 50 per cent. of the patients had a definite history of a blow on the head, and often a scar was to be seen on the scalp directly over the site of the tumour. It seemed possible that the trauma had the effect of stirring the villi or the surrounding endothelial cells into great functional activity. He described and illustrated the appearance seen in these cases, including the bony hyperostosis and unilateral exophthalmos. Upon operative measures he touched only incidentally, but it was sufficiently evident from the illustrations of different stages of the cases that the removal of these large tumours had frequently been brilliantly accomplished.

In conclusion, Professor Cushing said that research on this subject had not got farther than the threshold. For its further development a group of special workers must arise—men trained in neurology and also in the fastidious operative technique which intracranial operations for tumour demanded. The threshold had been reached with halting steps, and with assistance from many quarters. It was a far cry from the piece of flint used in primitive surgery to the circular hand trephine, and again to the electrically driven instrument. Neurological advance had depended not only upon great workers in this specialism, like Jackson and Horsley and Sherrington, but upon a multitude of labourers in other arts and sciences the connexion of which was not at first obvious—upon Michael Faraday and Henry Bessemer, upon Edison and Crookes and Röntgen, upon Lister and Pasteur and Simpson, upon workers with the microscope and in chemistry, and so on in an endless chain. The progress from the days when a piece of flint was drilled into the skull to let out evil spirits to the present time, when a brain tumour could be detected and removed, was merely the result of the adaptation of innumerable fragments of applied knowledge. All arts, like all people, were somehow related if their genealogy were traced back far enough into the past. Therefore he trusted that it might not vex the shade of the old philosopher who had given his name to that lecture that the subject chosen had been one apparently so remote from the scientific pursuits of Henry Cavendish as the study of a particular variety of intracranial tumour.

PREVENTION OF VENEREAL DISEASE.

National Council for Combating Venereal Diseases.

AT the annual meeting of the National Council for Combating Venereal Diseases, held on June 19th, Lord GORELL, who is retiring from the chair, gave a valedictory address. He regretted that pressure of work prevented him from continuing his presidency; he laboured also under the disadvantage of a dual rôle, because he held a Government position, and, the Council being in part subsidized by the Government, its work was necessarily subject to Government criticism. He thought that there was no reason to be dissatisfied with the present position of the Council. A year ago when he addressed the annual meeting a campaign of misrepresentation was proceeding from certain quarters. It would be too much to say that this had now disappeared, but it had certainly lessened in virulence. This was because, in his opinion, the British public was making up its mind on the merits of the situation. The Council had good cause for congratulation in the setting up of Lord Trevellyn's Committee of Inquiry, and in passing he would express gratitude to Lord Dawson for his labours in this connexion and for the courtesy with which he had received all the suggestions which the Council had made to

him. Lord Gorell believed that this Committee might find a *via media* in which all who were genuinely solicitous for the national welfare could meet and agree. Save in matters of finance, the Council was in a very strong position. Rather more than two years ago, when he was asked to take up the presidency, a well-known medical journalist begged him not to touch the question, because, for one reason, it was purely a medical question. Experience had proved to him that this was quite a misapprehension. The Council acted as a goad to Government departments, especially the Ministry of Health and the Board of Education. The numbers attending the clinics, which were 52,000 in 1918, 98,000 in 1919, and 105,000 in 1920, fell in 1921 to 84,000, and it was permissible to assume that this fall reflected a definite drop in the incidence of the disease. The subject of continuous treatment was much to the fore. The percentage of those giving up treatment before being cured varied in different clinics from 12 up to as much as 70. He referred to the compulsory measures which obtained in the Dominions, the United States, and Scandinavian countries, and quoted some figures from the province of Ontario which showed that out of 638 persons who unjustifiably discontinued treatment 400 were persuaded to return because a system of notification was in vogue. The Council had taken no decision as yet on this question. The Ministry of Health, which had stated that the time was not ripe for any general system of notification, was, he thought, excessively cautious in deprecating discussion of the subject. In conclusion, he begged that harmony might prevail within the Council, and that minorities who failed to gain their point should not break away and thus deprive the Council of their moderating influence.

Sir MALCOLM MORRIS proposed, and Mr. E. B. TURNER seconded, a vote of thanks to Lord Gorell, which was heartily carried. The business meeting of the Council was held in private, but we understand that the successor to Lord Gorell has not as yet been chosen.

Policy of the Society for Prevention of Venereal Disease.

At the recent congress at Plymouth of the Royal Institute of Public Health Mr. Wansey Bayly, honorary secretary of the Society for the Prevention of Venereal Disease, made a communication, putting into precise detail the policy of his society with a view to correcting current misunderstandings. The preamble to his statement was composed by Bishop Welldon, one of the vice-presidents of the society. It stated that the society stood by three main principles: (1) the duty of every good citizen to live a chaste life; (2) the office of medical science to prevent the consequences of sexual immorality; (3) the fact that venereal disease can be prevented by immediate self-disinfection, if such a measure is intelligently applied. It was admitted that disinfection might be occasionally inoperative through misuse or delay, but this fact was not an argument against its efficacy. The society looked with favour upon all curative measures, and approved the institution of venereal clinics. It taught that instruction in methods of self-disinfection should not be refused to male persons who had reached adolescence, to women who desired it, and even to younger persons at the discretion of their parents or guardians. It advocated the propagation of such knowledge as might tend to diminish the disease and its consequences by means of lectures and leaflets. This policy was elaborated under five headings, but, briefly put, it amounted to the instruction of those classes of the public just mentioned—that is, men above the age of 18, women on demand, and younger persons in special cases at the discretion of those responsible for their welfare—in the great importance of self-disinfection as a preventive at the time of exposure to risk, and in the methods of application of such disinfectant; and the ensuring of the sale of the disinfectants required, together with full instructions to such persons, and to such persons only, by means of leaflets supplied with the disinfectants at the time of sale, and by attendants at public conveniences on demand, also of lectures, and through medical officers of venereal clinics and those in charge of naval, military, and industrial units. The society also left itself free to advocate such further steps for the prevention of the disease as might from time to time be deemed advisable by its executive. Mr. Wansey Bayly made a strong appeal to the congress for reconciliation between the two societies concerned in this problem. He said that the principle of immediate self-disinfection was accepted by both, and the point of difference had been reduced to the academic question as to which of several methods of prevention, all valuable, was the most important. He appealed to the National Council to accept immediate self-disinfection as one of the weapons in the antiveneal campaign, because, with such acceptance, every obstacle to cordial co-operation between the two societies would be removed, and the two would work each along its own lines, but in support of the other, towards the common goal.

British Medical Journal.

SATURDAY, JUNE 24TH, 1922.

OXYGEN AT HIGH ALTITUDES.

THE news in the letter from General Bruce, received by the Mount Everest Committee and published in the *Times* last week, is of the highest interest to physiologists and to the medical profession generally, as well as to mountain climbers and the general public. A height of 27,200 ft. was attained with the help of oxygen, but by far the most interesting and significant fact is that Messrs. Mallory and Norton and Dr. Somervell reached on May 21st a height of 26,800 ft. without using oxygen, and, so far as the physiological difficulties were concerned, felt quite capable of climbing higher. Mr. Mallory's report, which General Bruce transmits, is a thrilling narrative of physical difficulties and dangers overcome, but their bodies had not reached the limit of physiological adaptation, and there was nothing in the narrative to show with any certainty that the limit would be reached at under 29,000 ft., the height of the summit. The height reached was 2,200 ft. greater than that attained in 1909 by the Duke of the Abruzzi and his party, who have hitherto held the record; they also used no oxygen. General Bruce is, however, apparently mistaken in thinking that the Duke experienced any serious physiological difficulties. To quote Dr. Filippi's account, the party made their way "through deep soft snow, to 23,480 and 24,600 ft. without exhaustion, without lowering of moral, without exaggerated difficulty of breathing, palpitation, or irregularity of pulse, and with no symptom of nausea, headache, or the like." It was thus quite an open question as to how much higher men could climb without oxygen; and the remarkable achievement described by Mr. Mallory leaves this question still open at a height of 26,800 ft.

At this height in the Himalayas in summer the barometric pressure is about 290 mm., or 11½ inches, and must be about 270 mm., or slightly under 11 inches, at the summit. An unacclimatized person is already in difficulties at 500 mm. (about 12,000 feet), and is likely to have a severe attack of mountain sickness after a few hours at this altitude. For unacclimatized persons to climb to altitudes corresponding to those reached by the expedition is quite out of the question. In the fateful high balloon ascent from Paris in 1875 the three balloonists lost all power of movement at about 300 mm. They could not even move their arms to take up the oxygen tubes which would have saved them. The balloon continued to rise till the self-recording barometer registered 263 mm.; but only one of the balloonists survived. As Paul Bert was the first to prove by experiment, it is simply the fall in the partial pressure of the atmospheric oxygen that causes all the physiological troubles at high altitudes. If pure oxygen were breathed there would, as he showed, be no physiological trouble at all up to a height of about 50,000 feet.

The factors concerned in acclimatization were very carefully investigated in the Royal Society expedition to Pike's Peak in 1911, and much additional knowledge has accumulated since then. The conclusion drawn from the measurements made on acclimatized persons was that there is not only, as had already been shown, an increase in the breathing and in the percentage of haemoglobin in the blood, but that the lung epithelium is actively secreting oxygen into the blood, thereby render-

ing it possible for the haemoglobin of the blood to become sufficiently saturated with oxygen. The probability that this occurs had already been indicated by the experiments of the Oxford School on carbon monoxide poisoning, and on the physiological accompaniments of muscular work; and the more recent experiments of Briggs on the respiratory factor in physical fitness have greatly strengthened the conclusions drawn from the Pike's Peak expedition.

Apart from the theory of oxygen secretion the achievements on Mount Everest would be altogether unintelligible, and the more so the more closely the whole of the phenomena of the blood gases and of acclimatization are considered. It is, for instance, well known to mountaineers that a man who is in good physical training is far less liable to mountain sickness than a man not in training. This is at once intelligible if training the lung epithelium in oxygen secretion is one of the main factors in ordinary physical training. In spite, however, of the strength of the evidence in favour of oxygen secretion, there are still a number of physiologists who cling firmly to the old theory that diffusion alone determines the entry of oxygen into the blood passing through the lungs. The controversy is therefore a live one, and the remarkable achievements on Mount Everest are certain to awaken it into renewed vigour.

More detailed reports of the expedition will be awaited with great interest. We almost hope, in the interests of physiology, that no more oxygen than is necessary for safety will be used in further climbs. Possibly, however, the men without the encumbrance of oxygen cylinders will yet outclimb those who carry them. There is nothing in our present knowledge to render such an outcome of the expedition improbable. Had liquid oxygen been available, thus rendering a light oxygen equipment possible, the chances would have been all in favour of the men with the oxygen. But with the relatively heavy equipment actually being carried the chances seem very even. Although the addition of oxygen to the inspired air gets rid of any immediate effects due to want of oxygen, the increased breathing due to additional carbonic acid formed in the muscles owing to the increased weight carried may more than compensate the advantages of the oxygen.

PUBLIC HEALTH IN AMERICA.

IN the *JOURNAL* of last week there was completed a review by Dr. J. C. McVail of the important jubilee historical volume of the American Public Health Association. The review indicated that a fundamental similarity exists in the health problems of all civilized countries, the chief differences being due to climate, density of population, and the conditions of industry. Stimulus to action came later in America than in this country, because large industrial populations accumulated later, and in the United States the average density cannot even yet be much more than one-tenth of what it is in Britain. But our machinery of government has had an advantage in simplicity of relationship between central and local authority apparently unattainable on the other side of the Atlantic. There, though the National Government does exercise various public health powers, individual States have a large autonomy, and have very diverse views both as to legislation and administration.

For example, want of uniformity in respect of vital statistics is marked. In some places even yet deaths are not recorded, and in Chicago, the second largest city of America, where child welfare is a prominent feature of municipal government and pasteurization of milk is compulsory, registration of births is not required. But

throughout the States progress is being made. Death registration now applies to over three-fourths of the population, and the area of birth records is extending.

Quarantine furnishes an illustration of recent progress in co-ordinative organization. Control was formerly local, and the promiscuous appointment of untrained officers, liable to frequent change owing to political influences, was almost the rule. This system had gradually been got rid of, and national control became complete in 1921. There is a double check on introduction of disease by immigrants, for officers of the United States public health service are stationed at all the chief ports of Europe, and also in the Philippines, China, South America, and the West Indies, so that before a voyage to the United States is begun precautions have been taken in respect alike of vessel, cargo, passengers, and crew. The United States have an extensive land frontier, and inspection stations are maintained along the Mexican border. Such an organization seems beyond criticism now that it is in the hands of the Federal Government.

As on this side, so in America, the first stimulus to sanitary improvement was the threat or occurrence of epidemic disease. In Canada plague and cholera were the influences at work, and when the fear departed preventive action quietened down, to be resumed when danger threatened once more. But throughout the great continent, just as at an earlier period in our own country, urbanization created evil conditions which called for permanent remedial measures. They had for their basis the principle of environmental cleanliness, which in practice meant the removal and prevention of effluvia nuisances and the systematic establishment of communal drainage and water supply. In these matters America followed the lead of Britain, but the leadership would have been reversed had the compelling conditions occurred first in America. Most unfortunately the schemes put into force were incomplete owing to their neglect of town planning and the essentials of healthy housing. That was no doubt inevitable, because of the want of foresight of the municipalities and the inadequacy of their powers, but the failure has left to the public of the present day a deplorable legacy of slums and slum areas in the New World as in the Old. The tragedy of it is that, owing to the great war resulting from German subservience to and complicity in the crimes of an unscrupulous megalomaniac, who boasted himself to be under the special protection of Heaven, civilization, which at last realizes the tremendous necessity of housing reform, appears for the time, in this country at least, to be almost bankrupt of the means wherewith to accomplish it.

In the absence of the guidance which science now affords to all who are in charge of the public health, the early policy of cleanliness, instinctively adopted, justified itself abundantly. Dr. Stephen Smith, the revered founder of the American Public Health Association, and now almost a centenarian, writes that the great achievements of the New York Health Department, working under an Act passed in 1866, were "the underdrainage of the soil, which prevented stagnant water and relieved the city of malaria; the removal of the cellar population to houses in the open air and sunlight; the removal of offensive industries from residential districts to the rivers; and the enforcement of rigid sanitary regulations." It might almost be said, indeed, that the pioneers of public health on both sides of the Atlantic, notwithstanding various errors, were, in the broad outline of their policy, actuated by a kind of inspired empiricism.

Then came the epoch-making work of Pasteur and Lister, and the beginnings of bacteriology, so that Professor Ravenel points out in the Jubilee volume, where he is both editor and contributor, how fortunate the American Association was in the circumstances of its

birth. Viewed aright, bacteriology both gave scientific proof of the worth of much that had been done without its aid, and guided into direct and definite channels effort that had hitherto included, besides what was valuable, some procedure that was of no account, whilst at the same time it opened up splendid new spheres of hygienic activity.

So directed and illumined, public health has progressed both on the old lines and the new. In his review Dr. McVail insists that cleanliness has acquired a scientific basis, and that filth removal is as fundamentally important as ever. Purity of air, water, milk, and food has, however, been given a new significance; and general measures for control of infectious diseases have become specialized to meet the discovered causes and conditions of individual maladies.

In modern public health work America has borne a great part. It has investigated and improved the methods of water purification, milk production, and food conservation, so that by preservative ways of dealing with articles of diet of almost every sort the world's available supplies have been much increased; Professor Prescott holds that in the absence of conservation "food prices would be prohibitive, the health of urban communities would be endangered, and starvation would be imminent in our large cities." At the same time the advances made in the science of entomology have been applied in America to the control of insect-borne disease. Dr. Leland Howard, indeed, in an optimistic article, holds it proved "that the tropics may be inhabited by the white race." He believes that the white man's world has been enlarged, and simultaneously his means of subsistence have been increased.

In modern extension of public health work, from environmental to individual hygiene, America again has taken its full share. In respect of tuberculosis and venereal disease, maternity, infant and child welfare, and school medical inspection, it is moving on lines more or less parallel to those followed in this country, though in respect of midwifery it is disappointing to learn from Professor Van Ingen that whilst "many States to-day have laws requiring registration of midwives," yet "few provide for their supervision, and up till recently almost none for their education."

These and some other services are still largely in a rudimentary or experimental stage, and in connexion with them all it would surely be useful if by conference or correspondence there could be a full interchange of views and experiences on questions of principle and practice still unsettled. Certain questions are suggested in the review. With regard to venereal disease, for example, what is thought in America on the rival policies of prevention and early treatment, which divide prominent members of the profession here into two groups, alike sincere and convinced, but in practice opposed? As to infant welfare, it is rather indicated that in America gifts of milk for babies are coming to be considered less satisfactory than education of mothers unaccompanied by material subsidy. A similar question ripe for discussion is that of school meals in their bearing on parental responsibility. There is also the related question of the duty of education authorities to act *in loco parentis* during strikes. It must often be very difficult to know where to draw the line in such circumstances, and advantage would result if the two great English-speaking peoples, equally interested in human progress and following the same general course in promoting it, could compare their methods and results. Whether any such comparison can be made in the housing problem seems doubtful, as the volume is silent on the subject of State or municipal contribution or action, though America shares in the insufficiency of dwelling-houses by which all industrial nations are at present afflicted.

THE MEDICAL OFFICER OF HEALTH FOR MANCHESTER.

At a meeting of the Manchester City Council on June 14th it was agreed to fix the salary of the new medical officer of health—when an appointment to the present vacancy should be made—at £1,700 a year for the first year, rising by annual increments of £100 to £2,000. According to the *Manchester Guardian*, in whose issue of June 15th a full report appears, Alderman Derwent Simpson, who brought the proposal forward as a recommendation from the Town Hall Committee, said that the post at present vacant would have to be filled, and, since the organized medical profession would not allow any of its members to apply for it at the salary of £1,500 offered, the Committee felt that it must face realities. At the salary originally offered they would not get the kind of man they wanted, nor would a man who accepted the salary have the support of his professional brethren in the city, and that would be a serious handicap to him in his work. An amendment was moved and seconded, that the commencing salary should be £1,500, to be increased to £1,700 in two years' time, and then to £2,000 by annual increments of £100, but the amendment was defeated by 52 votes to 43; a further amendment to delete the provision increasing the salary to £2,000 was also negatived, and the Committee's recommendation was approved. It will be remembered that when the Manchester City Council advertised last January for a medical officer of health in succession to Dr. Niven, a salary of £1,500 a year was offered, without any bonus or any promise of increments. The British Medical Association declined to insert the advertisement in the *British Medical Journal*, in which action it had the support of the Society of Medical Officers of Health and of the *Lancet*. It was pointed out that the offer of such a salary for such a post was a reflection not only upon the public health section of the medical profession, but on the whole profession, and the salary, if accepted, would certainly be used as a precedent by other large cities; in addition, the salary did not compare favourably with the salaries of the other important Corporation officials of Manchester. When the Manchester Corporation realized the strength of the position of the British Medical Association, amicable negotiations were entered into between a sub-committee of the City Council and representatives of the British Medical Association and of the Society of Medical Officers of Health. The result was what might have been expected when sensible men meet and exchange their views over a matter in dispute, and the present reasonable compromise was arrived at. The Manchester City Council is to be congratulated on taking, after some hesitation, the broad view of its responsibilities to the Manchester public. The British Medical Association will now do all that is in its power to enable Manchester to obtain a medical officer of health of the calibre it requires.

ECONOMY AND INFORMATION.

We notice that the Stationery Office has just issued the Report of the Registrar-General for Scotland at the price of £2 17s. 6d. This, we presume, is a fruit of the "Economy" campaign and an attempt to apply "business" methods to the publication of official documents. A logical consequence would be that the Report of the Registrar-General for England and Wales should be priced at a sum not falling far short of £5. If this course is followed, one of two things must inevitably happen. Either the free distribution of copies must be enormously increased or private citizens will cease to read such publications. We suppose the former alternative may be dismissed and that the Treasury is prepared to face the latter. In our judgement this is one of the grossest blunders yet perpetrated. The Chief Medical Officer of the Ministry of Health in his first report, in speaking of the prevention of disease, wrote: "The State and local authorities may do much, the medical man may do much, but the fulfilment of their purposes cannot be secured apart from an enlightened public opinion and a healthy way of life for the

individual." These words commanded the unanimous approval of the medical profession. The Stationery Office's contribution to the enlightenment of public opinion is, it seems, to require the public-spirited citizen to pay five pounds for an obviously fundamental statement of vital facts which had formerly cost him seven shillings. We are indeed rather curious to know how the new official prices have been determined. For instance, does the sum of £2 17s. 6d. for the Scottish report represent the quotient of the total cost of production of the last report divided by the total number circulated? If it does and if a sensible number of private citizens purchased the last report, it will not be surprising if the next issue but one, priced in the same way, soars to £10, while in due course the bulkier English volumes should compete with first editions of the *Complete Angler* for the dollars of the American collector. No doubt the illustrated papers will publish portraits and biographies of the North Britons whose patriotism has compelled them to expend £2 17s. 6d. on the record of Scotland's vital statistics. Merely from the business side one wonders whether this method, if it be the method adopted, is sound. We do not recollect any suggestion by Sir Eric Geddes's Committee that vital statistics should cease to be collected and the staff of the two General Register Offices disbanded. If statistics are to be collected it follows that somebody is expected to take an interest in the results. It may not even be too speculative to argue that a fair number of public officials must familiarize themselves with these results, and that, for this purpose, some copies must be printed. Therefore the cost of putting the document into print must be found, even if not a single private citizen, not even the secretary of an antivivisection society desirous to prove that vaccines have increased the death rate, would buy a copy. One would have supposed that a business man might argue as follows: "The largest item of cost of production must be met in order to enable the Government to do its ordinary business. At what price can I put the document on sale in order to defray the additional expenses of paper, machining and distribution, and, if I am lucky, recoup some of the standing cost of typographical composition?" The answer plainly depends upon the intensity of negative correlation between published price and demand. If the Stationery Office has really acted in this way, the wealth and the enthusiasm for knowledge of the general reader must be greater than we had thought possible. To the medical man what has been done, or is about to be done, is peculiarly exasperating. From the beginning of registration Farr set himself to make the annual reports not only accurate but interesting, and he completely succeeded. His successors loyally followed in his steps. We intend no slight upon those very able public servants, the late Dr. Ogle and Dr. Tatham, when we say that the standard of interest of the annual reports has been raised in the last ten years, and that the story Dr. Stevenson has been able to tell has not infrequently reminded us of the original series. The interest taken in the volumes by the general public has obviously been greater; we may even thank the propagandists who have spread knowledge of them for controversial purposes. That any step should be taken which will diminish that public interest would be unthinkable had it not, in the instance of Scotland, actually been taken. One has heard much in the press of bureaucrats, Whitehall limpets, and such-like evil persons. If they indeed exist, their satisfaction must be great. Secrecy is the impregnable defence of the Tite Barnacle family, and a department the knowledge of whose proceedings can be purchased only at the price of £2 17s. 6d. need fear little criticism. We picture to ourselves the circular letters of a Whitehall department in 1932, framed on the following lines: "I am directed to advert to your communication of the 1st inst. and to inform you that a full account of the Department's proceedings in the matter to which you refer will be found on p. 1 et seq. of the Annual Report, Cd. 221, obtainable from H.M. Stationery Office or through any bookseller for the sum of £50 inclusive of postage."

THE MOUNT EVEREST ACHIEVEMENT.

THE experiences of Mr. Finch and Captain Geoffrey Bruce, who reached 27,200 feet on Mount Everest, together with those of the party consisting of Mr. Morshead, Mr. Mallory, Dr. Somervell, and Mr. Norton, raise physiological problems which we discuss in an article on a previous page. It will be observed that the party which used oxygen only reached a point 400 feet higher than was attained by the party which did not resort to that method. The telegrams received by the Mount Everest Committee and published in the *Times* of June 16th and 17th, show that Finch and Geoffrey Bruce had made some preliminary experiments from the base camp established on the left bank of the East Rongbuk glacier at a height of 19,800 feet. General C. G. Bruce reports that certain alterations "had to be made in the face mask which, in the original design, did not allow the wearer to inhale a sufficient quantity of air. This required much adjustment. However, during numerous little expeditions, including one to the North Col, the full benefit of breathing oxygen in high altitudes was apparent. It appears that even if the oxygen apparatus be temporarily removed from the mouth, alarming and unpleasant symptoms are not experienced." It was apparently during the first week of June that Finch and Geoffrey Bruce made their record; they had camped for two nights at 25,000 feet, an elevation at which the first party had camped three weeks before. This earlier party had made a camp on the North Col, which is apparently about 23,000, and, accompanied by some Nepalese porters, spent a night at 25,000. Eventually, as has been stated, this party pushed on to 26,800. "Ultimately," Mr. Mallory writes, "the power of pushing up depended on lung capacity. The lungs governed the speed, making the pace a miserable crawl." The decision to turn back (soon after 2 p.m.) was determined by the lateness of the day, bad going owing to fresh snow, and the exhaustion of the party. Reading between the lines of Mr. Mallory's enthralling story it seems clear that the condition of all the members of the party was bad, and that, but for the kindness of the weather later in the day, they might never have got down. In addition to the difficulty of breathing, this party suffered much from cold. Even at the base camp on the East Rongbuk glacier (19,800 feet) night temperatures as low as zero (Fahrenheit it is to be presumed) were registered, and at the two upper camps temperatures as low as seven, eight, and nine below zero were common. Mr. Morshead, who had gone up with the others to the 25,000 feet camp, broke down there owing to indisposition, due, it was thought, to a chill, and the three who went on to 26,800 all suffered from frost-bite. This attempt, however, as General Bruce points out, showed that first-class porters could carry oxygen to 25,000 feet without employing it. When details of how the second party fared are received it will be interesting to learn to what extent they were helped by the oxygen apparatus, and whether its advantages made up for the extra weight.

ART IN INDUSTRY.

On the occasion of the President's reception at the Royal Society of Medicine on June 14th half an hour was spared for a pleasant little disquisition by Dr. T. M. Legge, H.M. Medical Inspector of Factories, on the subject of industry and art. Dr. Legge defined Art as the production of an atmosphere generally though not necessarily beautiful, but always wonderful. To those who had been brought up amid the Gothic traditions of public school and university it was a startling transition to be plunged into industrial life; yet, given imagination in the observer, a factory might well call forth something of the same emotion as a cathedral, and in the utilitarian interior of a great machine shop might be found what corresponded to clerestories and triforia and pillars of the nave. Modern industry with its 100-ton hammers and roaring furnaces had its impressiveness if not its beauty. Dr. Legge, however, as he developed his theme, rather dispraised the factory and exalted the mediæval craft guilds, where pride in work, leisure in its accomplishment, and a feeling after beauty, as well as honesty in production, were the ideals.

with the church taking the place of the trade union, and the patron saint the place of the shop steward. But it was evident that art in industry had not disappeared with the disappearance of the guilds and the decay of the guildhalls, because not a few modern artists had found their inspiration in chimneys rather than in trees, and in smoke rather than in pearly skies. He placed first among them the Belgian sculptor, Constantine Meunier, who managed in his delineations of hard physical toil to suggest the price which had to be paid for it—how the worker at the furnace paid in streaming sweat and posterior cortical cataract, and the worker in the mines in miner's nystagmus and the constant risk of explosion. But there were others who had treated industrial subjects with great feeling, among them Joseph Pennell, Frank Brangwyn, Muirhead Bone, and C. R. Nevinson, the last of whom had managed to suggest industrial fatigue by means of cubism. Dr. Legge concluded by showing with unqualified appreciation the modernist treatment of slag heaps, which made it evident that, properly viewed, the Black Country was as romantic as the Welsh hills. A vote of thanks to Dr. Legge was accorded with great heartiness, at the instance of Sir John Bland-Sutton. During the evening the guests had the opportunity of studying a series of specimens of Hispano-Moresco pottery, illustrating another aspect of art in industry, shown by Mr. Charles Mark. This science is now very difficult to find, and Mr. Mark, whose collection is one of the finest in existence, is to be congratulated on the success which has attended his efforts as a collector. The ware is of Asiatic origin, and can be traced back to the ninth century. It was manufactured by the Moors in Spain from the fourteenth to the seventeenth century, when the last maker died—and his secret died with him. The feature of the lustrous glaze of the pottery is its metallic iridescence, resembling the hues of certain butterflies. Most of the specimens of the best period are blue, including the Persian blue in Siculo-Arabian pieces—a colour that cannot now be produced. In the degenerating period copper colour was predominant. Majolica ware is supposed to owe its origin to this pottery; and undoubtedly the Italians were very keen collectors of the products of the Moors in Spain. The decorative patterns are various, including in the specimens shown the Christian cross on pieces such as a baptismal font, the Borgia bull on a large plate made for Calixtus III (the only Spanish Pope), heraldic designs, and borders of simulated or mock inscriptions to imitate inscriptions from the Koran. Actual texts from the Koran were never reproduced by the Moors. All the details in the patterns have a meaning. In the collection shown were many drug vases, but, unlike the Spanish jars, none of these are inscribed with the names of medicines. Most of the larger pieces of pottery were evidently intended for decorative purposes, being perforated with two holes for hanging on walls. The largest plate was 20 inches in diameter. The pottery is very brittle and liable to be chipped. The exhibition was most interesting, and the enthusiasm of Mr. Mark for his collection is amply justified. Specimens of modern Royal Lancastrian ware were also exhibited at the meeting, and formed an interesting comparison in glazes.

NUTRITION AND HEALTH.

We have received an instructive report made to the Public Health Department of Glasgow by the Medical Officer of Health, Dr. A. K. Chalmers, on the food values of diets supplied under the maternity and child welfare scheme. Dr. Chalmers shows that the food values of the diets supplied at the dinner tables to nursing mothers and children were such that there could have been hardly any recipients who experienced a continuous shortage of either protein or fat, the constituents of a diet most likely to be defective in the households of the very poor. The complete diet of these assisted persons was computed to supply 3,109 calories, derived from 86.5 grams of protein, 85.7 grams of fat, and 485.6 grams of carbohydrates. Dr. Chalmers compares with this the dietary of a family consisting of husband, wife, and three children (aged 13, 11, and 5 years), spending on food 19s. 9d.

weekly. This gave 2,216 calories as the portion of the mother, derived from 74 grams of protein, 46 grams of fat, and 362 grams of carbohydrates. The total yield in this latter diet is probably inadequate, but the balance of proteins and carbohydrates is precisely what has been recommended on good authority. Dr. Chalmers points out that there is a lack of co-ordination in our official food policy. "The contrasts at present existing," he writes, "may be illustrated by a family of seven persons, the youngest an infant of two weeks, where the husband has been out of work for one year and four months, and the total weekly income from relief is 35s. This is 18s. below the scale adopted by the Education Authority, which, for a family of two adults and five children, is assessed as requiring 53s. 2d." A very sensible leading article in the *Glasgow Herald* of June 7th comments upon Dr. Chalmers's memorandum in the following terms: "The medical officer has turned to practical use the opportunity thus offered of considering the actual food values of the meals supplied and of their relationship to the total daily requirements of those participating in them. But he goes further and opens up the whole question of the several responsibilities of the various authorities upon whom the Government has placed responsibilities for feeding. He is evidently not of opinion—and we agree—that this can be satisfactorily answered by three authorities working independently. The difficulty is to define the destitution line, and for this he suggests the amount of food necessary to maintain the body weight at rest. But here is the difficulty. Chronic underfeeding is known only by its result, there is little of a definite nature known as to its variations. It is a new aspect of national need and national obligation and must ultimately find a national solution." This report again raises a question which we have touched on frequently in these columns. We have expressed the opinion that the food problem of the post-war epoch is almost as urgent as that of the dark days of 1917, and that it is imperative to build upon the foundations laid by the Food (War) Committee of the Royal Society. We still know discredibly little about the quantitative side of the subject, and our estimates of the amount of food needed to maintain health are still lamentably vague. The country is passing through a serious industrial crisis; we may fairly hope that the worst is over, but in the present state of international politics we have no assurance that even more serious crises will not recur. It may become urgently necessary to employ our resources with the utmost physiological economy, but if the medical profession is to advise the national or local administrator authoritatively it must possess exact knowledge, which is at present lacking. At one time there was an expectation—which we did not share—that a large central department or institute would be established to promote nutritional research on a large scale. This expectation has long since gone the way of the "homes for heroes" and other dreams of the new heaven and earth which were to follow the downfall of the central empires. We must be content with something less grandiose. We are therefore glad to know that the Medical Research Council has set up a committee to consider what steps should be taken to extend our knowledge and to carry out preliminary inquiries. The membership of this committee is confined to a small number of recognized experts, and includes two of the medical staff of the Ministry of Health. It is obvious that work of this kind, involving both purely scientific and administrative considerations, can only be efficiently performed by persons in intimate relations with the academic and practical sides of the subject; the close liaison which has been established here, as in many other directions, between the Ministry of Health and the Medical Research Council is of happy augury. England lags far behind America with respect to the volume of its contributions to the study of human nutrition, although the subject is far more important to a small island state unable to feed its population from home-grown supplies than to the inhabitants of North America. We do not expect the new committee to solve in a few months, or even years, the

problems raised by Dr. Chalmers, but we are of opinion that the task assigned to it is one of the most important entrusted by the Council to any scientific committee.

HARVEIAN SOCIETY.

THE annual dinner of the Harveian Society of London, which took place on June 15th at the Café Royal, with the President, Sir William Wilcoxon, in the chair, was distinguished for the excellence of its after-dinner speeches and for the presence of many eminent legal guests. The loyal toasts having been honoured, "The Harveian Society" was proposed by Dr. J. W. Cock, who sketched the history of the society, which was founded ninety-one years ago. The President responded to the toast and welcomed the legal guests, with whom he had often appeared in court, both for and against. Sir James Galloway proposed the toast of "Kindred Societies," and spoke of William Harvey—"that magnificent old man"—of whose feasts history related several stories. Mr. James Berry responded for the Medical Society of London and Lord Justice Atkin for the Medico-Legal Society. The toast of "The Guests" was proposed by Dr. G. de Bee Turtle, and three delightful speeches, each excellent in its own style, were made in response by Sir Humphry Rolleston, P.R.C.P., Sir Edward Marshall Hall, K.C., and Sir Archibald Bodkin, Director of Public Prosecutions. The evening was brought to a close by the toast of "The Officers of the Society," which was proposed by the President, and Mr. D. C. L. Fitzwilliams responded.

OXFORD OPHTHALMOLOGICAL CONGRESS.

IN our issue of March 4th (p. 365) a note was published of the provisional programme for the next Oxford Ophthalmological Congress, to be held on Thursday, Friday, and Saturday, July 6th, 7th, and 8th, 1922. A copy of the official programme, together with additional information for the use of members has now been sent to us by the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton. Accommodation will be provided in Keble College from the evening of Wednesday, July 5th. The Congress will be formally opened on Thursday morning at 10.15 by the Master, Mr. Sydney Stephenson; after this a discussion on the significance of retinal haemorrhages will be opened by Dr. C. O. Hawthorne and Mr. P. H. Adams. In the afternoon papers will be read, and the annual dinner will be held in the evening. On Friday morning the Doyne Memorial Lecture will be given by Dr. J. Burdon-Cooper of Bath on the etiology of cataract. This will be followed by papers, and in the afternoon a discussion on methods of operating for cataract will be opened by Sir Anderson Critchett; to it contributions will be made by Dr. Lundsgaard of Copenhagen and Dr. T. Harrison Butler. On Saturday morning papers will be read by Mr. A. S. Percival and Dr. Butler. During the Congress scientific and commercial museums will be opened in the Department of Human Anatomy, and in the former a series of pathological specimens will be shown.

"PHYLLOSAN."

WE have received from the Managing Director of the Chlorophyl and Chemical Corporation, Ltd., a letter expressing his regret that, by inadvertence, in the circular advertising Phyllosan, issued with the forms sent out recently by the editors of the *Medical Directory*, the name of the *BRITISH MEDICAL JOURNAL* should have been included under the heading of "Authentic evidence of efficiency from the leading medical press of the world." He states that he was absent from England when the leaflet was prepared, and desires to exonerate the proprietors of the *Medical Directory* from any responsibility with regard to the announcement.

DR. GEORGE SCOTT JACKSON, C.B.E., D.S.O., has been appointed a Deputy Lieutenant of the county of Northumberland.

THE Garibaldi Franco-Italian prize offered by the French Surgical Society has been awarded to Dr. F. Rossi, of the University of Bologna, for his recent book on wounds of the thorax.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Case of Ronald Truë.

MR. KENNEDY asked, on June 15th, whether the attention of the Home Secretary had been drawn to the reported statement of Mr. Justice Avory, when charging the Grand Jury at Devon Assizes, that he very much doubted if the recrudescence of crime experienced after the war would continue to abate if the infliction of penalties of the law was to be left to the discretion of experts in Harley Street; and whether, seeing that such a statement indicated the need of a clear definition of the law relating to criminal lunacy, it was proposed to introduce legislation to remove any ground of judicial misunderstanding or divergence of judicial opinion. Mr. Shortt replied that he had seen a newspaper report of the learned judge's remark. As regards the latter part of the question the matter was one for careful consideration, but he was not prepared at present to say that legislation was either necessary or desirable.

Sir Donald Maclean inquired whether the Home Secretary would consult the Leader of the House as to what opportunity would be given to the House to discuss this matter, not merely in relation to the particular case, but on the general question of principle involved. Mr. Shortt said he would consult Mr. Chamberlain. At a later date Sir Donald Maclean pointed out that the subject could not be taken on the estimates, as legislation might be required, and that could not be raised on the estimates. Mr. Chamberlain replied that in the present state of public business he did not see how it would be possible to find a day for supplementary subjects, especially if the House was to rise in anything like good time, having regard to the probability that it would have to meet in the autumn in respect of Irish matters. On a further question, Mr. Chamberlain said he thought it might be possible for the subject to be discussed on a vote in Committee of Supply, provided that no mention were made of legislation.

In reply to another question Mr. Shortt said that since the Court of Criminal Appeal was established in 1908 the sentence of death had been respited and the prisoner removed to Broadmoor after statutory inquiry in eleven cases. He knew of only one case similar to that of Truë—namely, the case of Townley in 1884—when the prisoner was afterwards certified sane. In that case the sentence of death which had been respited was commuted to one of penal servitude for life, and the man was removed from the asylum to prison. In no recent case had the prisoner been certified sane under Section 3 of the Criminal Lunatics Act, 1884. There was nothing in the law to prevent a man being executed after he had recovered his sanity, but whether it was done was another matter. Mr. Shortt said that in eight of the eleven cases that had occurred since 1908, either the judge or the Court of Criminal Appeal, or both, while satisfied that the verdict of the jury was correct and that the prisoner had been properly found guilty of murder and not insane, in the legal sense, when he committed the crime, nevertheless suggested that it was desirable that further inquiry under the powers vested in the Home Secretary should be made as to the mental condition of the prisoner.

Pension Assessment by Medical Boards.—Mr. C. White, on June 15th, asked whether doctors and other persons employed by the Ministry of Pensions, though not allowed to alter the finding of medical boards, did in a large number of cases send the documents back to the chairmen of medical boards, suggesting that assessments should be changed, and almost invariably recommending a reduction of the assessments and bringing pressure to bear to effect such reduction. Mr. White asked, further, whether the Minister would issue instructions that no assessment by a medical board should be interfered with or altered in any way except by an appeals medical board or some other tribunal where the pensioner could be present or be represented. Mr. Macpherson said he was glad to be able to assure Mr. White that he was misinformed as to the procedure. His department had continually in operation some two hundred medical boards throughout the kingdom, and it did happen on occasion that the medical staff of the Ministry referred back to a board for explanation a case in which the assessment appeared to be either markedly too high or too low in the light of the clinical finding of the board. No pressure was, however, brought to bear on the board, the procedure being based on the free exchange of medical opinion upon questions of doubt or difficulty. The whole procedure of assessment was very carefully examined last year by the departmental committee of inquiry, who concluded their report on the subject with the statement that the last word as to degree of disablement was always with a medical board. Mr. White asked whether it was not the fact that many members of medical boards were making representations—confidential though they might be—to members of Parliament complaining of interference with awards that had been given. Mr. Macpherson replied that Mr. White's statement was quite inaccurate. In case after case the assessment was increased. If Mr. White or any other member had a case to bring to his notice he would be glad to inquire into it. Mr. White rejoined that he would produce evidence. Mr. Cairns inquired if a man had certificates from three medical men saying he was totally disabled by the war, and doctors said he was healthy before

he went to the war, and his employer said he had never missed a day's work, how was it that man could not get a pension? Mr. Macpherson replied that the man had the right to appeal to an independent tribunal. Mr. Cairns said that the man had appealed twice.

Treatment for Neurasthenia.—Mr. C. White asked, on June 15th, whether neurological hospitals at Ashurst, Oxford, and others in London were being closed permanently; whether the patients in these hospitals were being sent to army hospitals at Netley and other places where the treatment was quite unsuitable for such cases. In such case the Minister would reconsider the matter. Macpherson replied that the demand for treatment for neurasthenia was, he was glad to say, decreasing, and hospital accommodation was being correspondingly reduced. In-patient treatment for neurasthenia was still being provided at Ministry institutions, of which the Welsh Hospital at Netley (as distinct from the military hospital there) was one; there was no intention of making any other arrangements. He could not say whether or not the Ashurst Hospital was closed.

Condensed Milk.—Sir A. Roscawen stated, on June 15th, that the quantities of sweetened condensed milk, machine-skimmed or separated, imported in April and May of 1921 and 1922 were as follows:

		April.	May.
1920	...	cwts. 31,725	cwts. 74,563
1921	...	66,797	77,689
1922	...	109,325	115,443

The Minister added that according to his information there had in recent months been a very large reduction in the home manufacture of condensed milk. Sir Alfred Mond, on another question, said he understood that there was agreement amongst a number of witnesses who appeared before the Departmental Committee on Condensed Milk Standards as to the standards which they wished to have fixed. The Committee, in recommending somewhat lower standards, considered it undesirable to cut off a substantial portion of the national supply of the commodity. His own powers in the matter were limited by what was necessary for the prevention of danger arising to public health, and he should therefore not feel justified in fixing any standards which could not be attained generally. He was not prepared to make regulations fixing such standards as were suggested by the trade interests, but he was prepared to make regulations to require appropriate labelling. The Departmental Committee's report would be published if there were any general desire for this to be done, but not otherwise.

The Sale of Cocaine.—Mr. Ramsden, on June 15th, wished to know whether the Home Secretary was aware of the remarks made by the stipendiary magistrate at Marlborough Street police court when he sentenced a prisoner for selling cocaine to the maximum penalty allowed by the present law, and to the rider of the jury who held an inquest on a young girl who had purchased cocaine from some man, and whether the Minister would consider an amendment of the law to increase the maximum penalty. Mr. Shortt responded that he had seen newspaper reports of the cases. The question of amending the law was under consideration.

Water Supply.—Sir A. Mond informed Mr. Gilbert, on June 14th, that at present there was no shortage of water for London, nor, having regard to the available supplies, was the situation likely to become generally serious, even if the drought continued. It was important, however, that the public should exercise all reasonable care. The Minister added as regards the country generally there was no serious shortage, although some places were already in difficulties. The conditions differed greatly, even in neighbouring districts, but the outlook if the drought continued was least satisfactory in the south and south-east. The Ministry was assisting authorities who were, or who were likely to be, in difficulties.

Indian Medical Questions.—Mr. Hogge asked, on June 20th, why the concession of proportionate pension was not given to officers of the Indian Medical Service in permanent civil employment, and why such officers did not receive the same privileges and concessions as had been or might be accorded to other civil officers as a result of the detriment to their prospects and the altered conditions of service resulting from the reform scheme. Earl Winterton said that officers of the Indian Medical Service in permanent civil employment were permitted to retire on permanent pensions if they could not be employed in military duties in which under the terms of their employment they were always liable to recall. He was in communication with the Government of India in regard to the applicability of these conditions to officers who by reason of the length and nature of their civil employment had had a reasonable expectation of continuance therein up to the time of their normal retirement.

Summer Time Bill.—On the second reading of this measure, which came down from the Lords, Mr. Shortt, on June 14th, stated that it was necessary because the power of establishing summer time by Order in Council would cease this year unless there was a measure proposed to make the alteration permanent. The measure proposed to make the alteration permanent from April to September, inclusive. Mr. Shortt recognized, however, that a great objection felt by agriculturists to the shifting of the hours and he offered to consider in committee a curtailment of the period during which summer time should operate. After considerable debate the Home Secretary said he was willing, not only that the bill should be annual, but that the period of summer time should be reduced at each end by not less than three weeks. The measure was read the second time by 207 votes to 26.

England and Wales.

LONDON'S WATER SUPPLY IN A DRY SUMMER.

DEATH rates have been correlated with density of population and with the water consumption of the large towns, and the results may be briefly summed up in the statement that the death rate increases in direct ratio with the density of population and inversely with the consumption of water. So wide a generalization would require many qualifications before being literally accepted, but the statement, nevertheless, expresses the general truth that an abundant water supply is a health asset of the highest importance to town populations. There was an adage in the army, "A wet camp is a healthy camp," which expresses the same truth, and there is a very proper apprehension, to which the daily press has recently been very much alive, that anything that threatens in any considerable degree the water supply of great cities is to be regarded seriously. Of the great agglomerations of population in this country London is, in this respect, the least well off. Manchester, for instance, and the densely populated area of which it is the centre, have taken care to be much better off. In London, as things are, a curious source of consolation is found in the fact that there is a large margin of what is regarded as wasteful consumption, and a concerted effort to reduce this is observable in the remarks of all our public mentors. Now it is quite true that when there is a scarcity of water misuse and extravagance in its consumption are grave offences, and we do well to discourage and even penalize such wasteful practices. Among these are mentioned leakage in main and service pipes, defective taps and fittings, excessive use of water for personal ablution, washing motor cars, and watering gardens. During the drought of last year efforts to check these were made with more or less success, and economy was pushed even to the extent of reducing or abstaining altogether from street watering and sewer flushing. The rainfall during the first four months of this year was in excess of the average, but the amount in May was only about half the average. Nevertheless there would probably have been no difficulty this year, in spite of the dry June, but for the deficiency resulting from the drought of last year. Meteorology is not yet in a position to prophesy far ahead, and the vagaries of the English climate are notorious. A few weeks hence we may be complaining of Lammas floods, and next year may be unduly dry. Unfortunately the water supply is a case in which averages do not work. The duty of the water authority is to provide a sufficient quantity of water to the population for which it is responsible. It is during prolonged dry weather that street watering and drain and sewer flushing are most necessary. Dust in the streets and foul accumulations in the drains and sewers are among the environmental conditions which produce ill health; even leakage from defective taps helps to flush drains, and economy in water for ablution can be justly advocated only because of a failure to supply what is a supreme civic need. The washing of motor cars achieves something more than a mere æsthetic satisfaction, while the withholding of water from gardens during dry weather inflicts a loss upon London in the destruction of food supplies, which however insignificant in quantity are of importance to a population otherwise dependent upon stale or preserved foodstuffs. If our population is to live in huge communities such as London the aim must be to make the dry-weather supply of water so abundant that it will not be necessary to plead for economy during an exceptionally arid season. It is a paradox that waste of water is then from the health standpoint least wasteful. Some recent references in the newspapers seem to suggest that the old plans for obtaining water for London from Wales may be revived, but we take it that the present financial position puts any such scheme quite out of the question.

LONDON ASSOCIATION OF MEDICAL WOMEN'S FEDERATION.

A dinner of the London Association of the Medical Women's Federation took place on June 13th at the St. Pancras Hotel. Dr. Louisa Martindale was in the chair, and eighty-four members and guests were present. Speaking after dinner the President said that this was actually the first dinner ever given by the London Association of Medical Women's Federation, as before the war there existed only a London Association of Registered Medical Women, and the present association had been formed during the war chiefly owing to the energy of Dr. Jane Walker. Dr. Jane Walker sketched the formation of an international federation or association of

medical women; the constitution of which it was hoped to establish at a conference to be held in Geneva next year. Lady Barrett, the new President of the Medical Women's Federation, welcomed the guests, for whom Lady Rhondda and Dr. Carr responded. Between the speeches Dr. Aitken sang several groups of songs, among them some composed by the accompanist, Dr. A. G. Phear.

LONDON HOSPITAL MEDICAL COLLEGE.

The prizes won by students of the London Hospital Medical College during the past session were distributed on June 19th by Mr. T. H. Openshaw, C.B., C.M.G., who is retiring from the post of senior surgeon after more than forty years' service on the staff of the London Hospital. The chair was taken by Mr. W. M. Pryor, chairman of the college board, who was supported by Mr. J. H. Knutsford, Lord Dawson, Professor J. H. Knutsford, and Mr. E. W. Morris (honso governor). The prizes Mr. Openshaw thanked the college board for inviting him to do so and thus giving him an opportunity to address the students. He was carrying away most pleasant memories from the hospital, which, he said, offered the advantages of a larger surgical practice than any other in the kingdom. It was only by making the most of the great opportunities for obtaining knowledge and skill the hospital afforded that its students could maintain the splendid character the London Hospital had won among the medical institutions of the empire.

Correspondence.

THE INTERSTITIAL GLAND AND SEX PROBLEMS.

SIR,—I am much obliged to your two correspondents, Dr. Douglas Howat and Surgeon Rear-Admiral Marsh Beadnell, for their courteous comments on my paper, "The interstitial gland." Being very little of a biologist, I am not in a position to discuss with the former the interesting points to which he refers. On these matters we seem still to be very much in the domain of theory, so that each of us is at liberty to select the particular hypothesis which seems to him best to fit in with the facts. I cannot personally bring myself to subscribe to the view that maleness resides in one maternal ovary and femaleness in the other. Nature does not seem to have evolved dual organs with this kind of end in view. She did not, for example, adapt one eye for distance and the other for near work.

Rear-Admiral Beadnell's views on the question of homosexuality are what may be described as the orthodox views, very clearly expressed. Like Newman's *Apologia* if you admit the premisses you cannot escape the conclusions. But it is precisely for a revision of these very premisses that I am venturing to appeal to Rear-Admiral Beadnell and other thinking members of the profession. If one holds firmly to the opinion that everything homosexual is necessarily unnatural and vicious, then discussion is clearly useless. I make so bold as to plead for a frank and general recognition of a fact which for the last twenty years has been forcing itself upon my conviction with increasing insistence. It is that there is, in very sooth, such a thing as a third sex. There are certain men who are homosexual, who can no more help being homosexual than they can help the ebbs of their stature or the colour of their skin. In no sense of the term can these men be described as vicious. They are for the most part hard-working respectable citizens. Many of them are greatly gifted. Some of them worthily fulfil very high positions in very responsible callings. The majority of them are just as sensitive to the canons of right and wrong as the most notorious paterfamilias. A large number of them would give all they possess to become heterosexual.

After the age of 40 a medical man receives very intimate confidences in the consulting room, and I feel sure that there must be a very large number of my confrères, qualling my 60 years, who could testify to the truth of the above statements.

I am not denying that homosexual practices are indulged in by the heterosexual from purely vicious motives, and I will gladly countersign any words of condemnation and opprobrium (I am sure they would be vigorous) which Rear-Admiral Beadnell cares to apply to such people. I am, however, no more concerned with them than I am concerned with exhibitionists or with other degenerates who are rightly

kept under control. I am merely contending that homosexuality as a state is so prevalent amongst perfectly respectable people that it is no longer scientifically sound to regard it as altogether pathological; still less is it reasonable to stigmatize it as vicious.

There are certain physical and mental characteristics of this third sex which, to the seeing eye and sensitive ear, are quite unmistakable. There can, I think, be no doubt that these characteristics are determined by a certain admixture of the male and female interstitial glands in the hormone make-up of the individual, and it seems reasonable to hope that attention to these glands, given in time, may save people from this rather sinister indeterminate state.—I am, etc.,

London, W., June 19th.

LEONARD WILLIAMS.

A PULMONARY SIGN IN ACUTE INFECTIONS OF THE BILIARY TRACT.

SIR,—I was very interested in Mr. Wilkie's article, as it confirmed a few of the observations I made some years ago, and published in the *Indian Medical Gazette* in July, 1919. I then pointed out the progressive changes in the lungs, and the alterations in the tonus and level of the diaphragm, in acute abdominal lesions.

Two main factors are responsible for these alterations:

1. The reflex changes produced by the pain caused by the lesion.
2. The mechanical effects of the alteration in the intra-abdominal pressure.

The first produces an increase in the tonus of the anterolateral abdominal muscles, which are expiratory. This reflexly inhibits the tonus of the antagonistic inspiratory muscles, including the diaphragm. This relaxation explains the diminution in the range of the respiratory movements and the elevation of the diaphragm, in any lesion producing pain or rigidity in the abdominal muscles. If progressive and unilateral the lesion will produce complete absence of respiratory movements on the corresponding side. Accompanying the diminution in the respiratory movements will be found a progressive collapse of the lung, and complete abolition of the former will produce complete collapse of the lung. These facts I discovered by screening and examining various cases, and confirmed during operations on liver abscesses. For further details I refer the reader to the original article.—I am, etc.,

Cardiff, June 16th.

D. J. HARRIES.

AN AORTIC MURMUR.

SIR,—In case anyone is interested in the aortic murmur which I described in the *JOURNAL* of May 13th, I would like to put before you some further information with which Sir Clifford Allbutt was good enough to supply me. He says that he has been familiar with the murmur for half a century and has restored many youths to fields of athletics who had been warned off on this account and that he owed his knowledge of it, and of the muscular mechanism producing it, to his friend the late B. W. Richardson, in whose works somewhere I would find it called the "carpenters' murmur." Writing further in reply to a query from me as to why such a common murmur was not described in textbooks or clinical manuals, he said, "See in Allbutt and Rolleston's *System*, vol. vi, page 510, para. 2, line 3—yet it is only an incidental allusion." He also says I have done good service in drawing attention to this point, but I cannot see how, unless the matter is taken up by authors of standard textbooks or clinical manuals.

Major Moss, writing in the *JOURNAL* of June 3rd about a "postural" murmur, may be describing the same one, but as he mentions raising of the arms as the essential factor I doubt it.—I am, etc.,

Perth, June 10th.

THOMAS LINDSAY.

THE CASE OF MR. F. W. AXHAM.

SIR,—Dr. J. S. Manson and Dr. J. Price Williams must excuse me if I refrain from entering on the controversial issues which they propose and which were expressly excluded from my former letter. My sole object was to point out the, as I think, unfortunate position in which the profession has been placed. Where the responsibility for this position rests is a question for the individual judgement.—I am, etc.,

London, W., June 19th.

C. O. HAWTHORNE.

SOCIETY OF APOTHECARIES OF LONDON.

SIR,—As there appears to have been some misapprehension in certain quarters as to the effect of the recent discontinuance of the trading operations of the Society of Apothecaries, I am directed to ask if you will be so good as to allow me to state exactly what has taken place.

The Society has discontinued both its wholesale and retail trade in the manner which has already been announced in the press, but has made no other change whatever. Its work and duties as a medical and surgical licensing body, examining for and conferring the diploma of L.M.S.S.A., and also granting a certificate in dispensing, continue as hitherto, and will be in no way affected by the discontinuance of the Society's trading operations.—I am, etc.,

Apothecaries' Hall, London, E.C.4, June 19th.

BINGHAM WATSON,
Clerk.

SENIOR SURGEON COMMANDERS, R.N.

SIR,—The retirement scheme for naval officers recently promulgated by the Admiralty only serves to emphasize the injustice under which senior surgeon commanders suffer. Had we been redundant executive, engineer, or paymaster officers we should have had inducements held out in the shape of increased pensions and a lump sum down to retire voluntarily. Without being invidious it can be readily imagined that the least brilliant in their respective spheres accept these inducements with avidity. We, on the other hand, are retired compulsorily, lose several years' full pay and chances of promotion, and get not a penny compensation, my lords evidently thinking that a stereotyped letter of thanks for our "long and zealous service" and an honorary step in our embrown rank are sufficient. Both are pretty, but entirely useless, and we thank my lords for nothing.

As a concrete instance of the different conditions of retirement I compared notes with my late captain, a younger man by five years. He retired voluntarily on a pension of £875 and a bonus of £750. I retire compulsorily on £600 and no bonus. My pension is liable to 20 per cent. reduction, and I must also reduce it by commuting to provide capital for a start in civil life—a risky proceeding at an age which experience teaches me quite precludes me from obtaining any public appointment.

I do not grudge the above-mentioned captain his fortune, but we senior surgeon commanders have never had a chance to attain captain's rank. All chance was extinguished by our earlier compulsory retirement.

In my earlier years in the service the engineers and paymasters looked to the medical branch for a lead in the conditions of service of the non-executive branches. My later years have seen them climb over our shoulders, and in the process push us into the background, where my lords seem to have every intention of keeping us when it comes to equal treatment.

The engineers in numbers and influence are now almost the equal of the executive; the paymasters through the secretaries have the ear of every admiral in the service; senior surgeon commanders have—the British Medical Association. Hence this letter.—I am, etc.,

June 9th.

LATE SURGEON COMMANDER, R.N.

MEDICINE AND THE HUMANITIES.

SIR,—Of the discussion of a medical student's career by the General Medical Council it is difficult to say whether it is tragical or comical. The obsession of examinations and marks, as the sole outfit for life for a member of the medical profession, is amazing. Sir Arthur Chace notwithstanding. What does it matter whether the final examination is taken separately or together? To lead students on for number of years with a finesse to ultimate rejection is an injustice to them and their parents. Talk of one examiner only being present, why not three? One of them might possess a humanistic education and a considered view. I venture to say there is more of value and in accordance with the spirit of the times in the Hunterian oration of Sir Charters Symonds than in the whole of the discussion. Sir Thomas Paget, Greenhill, Pye-Smith, Goodhart, and Osler were mere medical men and surgeons; neither are Sir Thomas Barlow and Sir A. Garrod of our own day. They influenced characters of the students for a generation. Homer's *Odyssey*, Plutarch's *Lives*, Goethe's *Wilhelm Meister*, or Carlyle's *French Revolution* (even in a translation) for the curriculum would do good to many minds and give them at least some

and basis in life, some glimpse of the "Roman Road" and Arnold's "sweet city with her dreaming spires."—I am, etc.,
London, N.W., June 11th.
RICHARD GILLBARD.

*** We are reminded of Sydenham's reply to Sir Richard Blackmore, who, when a student, asked what books he should read for the study of medicine: "Read *Don Quixote*; it is a very good book; I read it myself still."

The Services.

INDIAN MEDICAL SERVICE.

THE annual dinner in London of officers of the Indian Medical Service was held at the Trocadero Restaurant on June 14th. Lieutenant-Colonel John Anderson, C.I.E., was in the chair, and the only guests were representatives of the *British Medical Journal* and the *Lancet*. The officers present numbered 78, as follows:

Major-Generals: Sir R. H. Charles, G.C.V.O., T. Grainger, C.B., G. F. A. Harris, C.S.I., Sir P. Behir, K.C.I.E., C.B., C.M.G., H. Hendley, C.S.I.

Air-Commodore: D. Mauro, C.I.E.

Colonels: C. W. Carr-Calthrop, C.B.E., J. K. Close, J. Crimmin, V.C., C.B., C.I.E., C. R. M. Green, A. J. Macnab, C.B., C.M.G., J. J. Pratt, C. N. C. Wimberley, C.M.G., W. A. Quayle.

Alcock, C.I.E., W. G. P. C.I.E., W. H. Cadge, O.B.E., J. Hirsch, C.I.E., J. A. Black, C.I.E., D.S.O., E. V. Hugo, C.M.G., J. G. Hulbert, S. Hunt, H. Kirkpatrick, W. B. Lane, C.I.E., C.B.E., W. H. Leonard, A. E. J. Lister, J. Lloyd-Jones, F. P. Mackie, O.B.E., C. H. L. Meyer, A. Miller, T. R. Mulrooney, A. Murphy, O.B.E., S. E. Prall, J. W. F. Rait, Sir L. Rogers, C.I.E., H. Smith, C.I.E., R. Stecu, A. Street, T. H. Symons, O.B.E., C. Thomson, M. H. Thornely, W. H. Thornhill, W. Vost, J. H. Tull Walsh, S. P. James, C. Duer, H. J. Walton, D. P. Warlick, H. G. L. Wortabet, A. C. Younan.

Majors: F. A. Barker, O.B.E., J. W. Barnett, B. Gale, W. Giltitt, C.I.E., J. J. Harper-Nelson, O.B.E., M.C., N. H. Hunne, H. H. King, A. S. M. Peebles, J. Taylor, D.S.O., W. A. M. Jack, O.B.E.

Captains: B. Fraser Beaton, H. J. M. Carsetjee, D.S.O., S. M. A. Farnki, F. S. Goss, M.C., J. M. R. Heuvers, H. Kingston, J. C. John, O.B.E., P. Savage, P. Verdou, C. A. Wood, M.C.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 17th the following medical degrees were conferred:

M.B., B.Ch.—T. B. Watson.
B.Sc.—W. J. D. Smyth.

VICTORIA UNIVERSITY OF MANCHESTER.

Mr. E. D. TELFORD, M.A., B.C.Camb., F.R.C.S., at present lecturer in Practical Surgery in the University and a member of the honorary staff of the Manchester Royal Infirmary, has been appointed Professor of Systematic Surgery in succession to Professor J. W. Smith, who will vacate the chair in September next.

Mr. E. J. Sidebotham, M.A., M.B.Camb., is retiring from the post of lecturer in Practical Bacteriology and Microscopy and deputy-director of the Public Health Laboratory. The Council, in accepting with regret the resignation, expressed their gratitude to Dr. Sidebotham for his loyal and devoted services to the University, and for the valuable services rendered to the public health department during nearly a quarter of a century and also for the efficient manner in which he conducted its affairs during the illness and after the death of the late Professor Delapine.

Mr. Albert Haworth, M.Sc., M.B., Ch.B., has been appointed assistant lecturer in Chemical Pathology.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following are the successful candidates at the recent examination for the Primary Fellowship:

D. J. Batterham, R. A. Brews, D. A. Briggs, E. P. Brockman, M. B. S. Button, D. Chamberlain, G. O. Chambers, J. M. Clarke, A. M. Clare, J. J. Coghlan, W. D. Doherty, H. A. Dunlop, W. H. Gervis, C. Gill-Carey, K. H. Gillison, A. Goodwin, J. Gray, E. F. Guy, A. C. Halliwell, A. C. Hampton, H. V. M. Jones, A. C. King, A. J. King, R. H. Lila, Marjorie E. Knowles, J. J. Lewinstein, N. L. Lochrane, R. H. Lila, A. C. MacLeod, S. M. Majumdar, S. M. Milner, D. W. C. Northfield, M. A. Paul, V. L. Parmar, E. L. Robert, F. W. Roques, J. S. Rowlands, B. G. Schofield, W. G. Sears, A. G. Smith, H. J. Taggart, G. B. W. Walker, R. L. Williams, W. R. Williams, H. G. Wimbush, A. J. Wripley.

THE following are the officers of the Röntgen Society for the session 1922-23: President, Sir Humphry Rolleston, K.C.B., F.R.C.P.; Vice-Presidents, Sir W. H. Bragg, F.R.S., Sir Ernest Rutherford, F.R.S., and Dr. A. E. Barelay; Honorary Treasurer, Mr. Geoffrey Pearce; Honorary Secretaries, Dr. E. A. Owen and Dr. Russell J. Reynolds; Honorary Editor, Dr. W. G. C. Kaye.

Medical News.

Mr. H. J. WARING, Dean of the Faculty of Medicine of the University of London, has been elected Vice-Chancellor of the University for 1922-23, in succession to Sir Sydney Russell-Wells.

Dr. J. W. MCLEOD, O.B.E., M.B., Ch.B.Glasg., Lecturer in Bacteriology at the University of Leeds, has been appointed the first occupant of the Sir Edward Brotherton Chair of Bacteriology in that university.

AT the annual general meeting of the Royal Society of Medicine, which will be held at 5 p.m. on July 6th, the election of Sir William Hale-White to be president in the room of Sir John Bland-Sutton will be proposed. The annual dinner will be held on the same evening, at 8 p.m., at the Victoria Hotel. Fellows are entitled to bring guests. The charge is 12s. 6d. each, exclusive of wine; the necessary amount, together with the name of any guest, should be sent to the Secretary of the Society, 1, Wimpole Street, W.1, as soon as possible.

We are informed that Dr. Eric Pritchard has been appointed Medical Director of the Infants Hospital, Vincent Square, Westminster, and that the medical staff of the hospital is to be reorganized and the work widely developed, in order to fulfil the Committee's intention of making the hospital a centre for research and teaching in connexion with infant welfare.

COMMEMORATION DAY at Livingstone College, Leyton, Essex, was held on June 9th, when the Secretary of State for Scotland, the Right Hon. Robert Munro, presided. In summarizing the year's work Dr. Tom Jays, the Principal, said that fifty-one students of eight nationalities, representing twenty-six missionary societies, had attended the college during the vacation course in July and the present session. News from old students, of whom over 600 had gone to the mission field, showed how necessary and valuable the college training was to missionaries in their isolated stations. Mr. Robert Munro said that such a training in medical knowledge as was received at the college was not only proper but essential for men and women who would be situated at distant outposts of the empire, far removed from medical advice and skill. He made an appeal for funds for the college, for it was a tragedy that an institution like that should be crippled and cramped for want of funds. Old students of the college testified to the value of the medical training to missionaries abroad.

THE National Academy of Medicine at Buenos Aires celebrated the centenary of its foundation on April 18th. The rector of the university, Dr. José Arce, presided, and an historical address was delivered by the president of the academy, Dr. E. Canton. Among the announcements made was that an institute of experimental medicine, the first of its kind in South America, had been founded. A prize of a gold medal and 5,000 dollars was awarded to Dr. P. Belou for his stereoscopic atlas of the anatomy of the ear.

A BEAUTIFUL tablet to the members of the 1st Welsh Field Ambulance (R.A.M.C.T.) who fell in the late war was unveiled at Christ Church, Ebbw Vale, on June 10th by Major-General Lord Treowen, C.B., C.M.G. The A.D.M.S. Welsh Division and a number of the old officers and men were present. This unit is now disbanded.

THE annual meeting of the School Medical Group of the Society of Medical Officers of Health will be held on Saturday, June 24th, at 3 p.m., at the society's offices, 1, Upper Montague Street, Russell Square, W.C.

In a note in last week's *JOURNAL* (p. 931) on the "Voyage d'Études Médicales" to Bordeaux and the Pyrenees, starting on August 26th, it was stated that applications should be sent to the secretary, Dr. Gerst of Paris. We are now informed that applications should be made to Mademoiselle Blaise, Chef du bureau des stations thermales, Office Français du Tourisme, 56, Haymarket, London, S.W.1.

THE first International Congress of Open-Air Schools, organized by the League for Open-Air Education, will be held at Paris, under the presidency of M. Merlin, Senator for the Loire, from June 24th to 28th. The subscription of 20 francs should be sent to the treasurer, M. H. G. Richter, 72, Rue de Rome, Paris.

Dr. P. CHALMERS MITCHELL, F.R.S., has been elected a vice-president of the Cremation Society of England. We are informed also that the Society has been asked to convene a conference of cremation authorities which will probably take place in London early in November next.

THE twelfth edition of Taylor's *Practice of Medicine*, edited by Dr. E. P. Ponson, with the assistance of Dr. C. P. Symonds and Dr. H. W. Barber, physicians to Guy's Hospital, is nearly ready for publication.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Athology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

TREATMENT OF PSORIASIS.

THE following are among the replies received to the inquiry from "A. B. S." published on June 17th (p. 932):

Dr. HENRY WALDO (Clifton, Bristol) writes: I tell patients with psoriasis that it is incurable. It tends entirely to clear up of its own accord, especially if the patient remains in bed, but it always recurs. It has a way of running into pityriasis rubra, and especially after active local treatment. For the case mentioned, the daily application of linimentum calaminæ B.P. codex allowed to remain on would seem suitable; its slight greasiness is an advantage. A warm bath should be taken once or twice a week with silted soap and after drying a little olive oil smeared on. Any obstinate patch should be painted with engallol (pyrogallol mono-acetate), using a bristle brush, and then applying the lin. calaminæ over all. Internally parathyroid substance gr. 1/10 (Parke, Davis, and Co.) should be swallowed twice daily; it acts by slightly increasing metabolism and regulating the calcium content of the serum.

Dr. LEONARD J. KIDD (London) writes: In 1913 Leopold-Lévy got excellent and rapid results in obstinate cases of priginous psoriasis by giving once a day a cachet containing 3 grains (0.20 gram) of powdered testis. Brisson says the testis is rich in sulphur; and Brown-Séquard long ago found that testicular substance was quite as effective therapeutically in women as in men. Let "A. B. S." stop all other treatment while he tries testicular substance. When benefit follows, it comes usually quickly.

Dr. G. H. WAUGH (Rugby) writes: Let me suggest a simple form of treatment which I have not seen or heard mentioned elsewhere. It is to anoint thoroughly, by gentle massage, all the patches and surrounding skin with glycerin and rose water mixed in equal parts. Thus, for patches on the shin anoint the whole leg; on the forearm anoint from wrist to elbow, and leave the application on, no bandaging being required. This treatment relieves the itching immediately and cures in a few days.

Dr. HALDIN DAVIS (London, W.) writes: In the first place it is evident that the case is now one of acute dermatitis, and should be treated as such, with soothing applications such as zinc cream. Water and watery lotions should be avoided, and the necessary cleansing of the skin should be carried out with olive oil or liquid paraffin. All energetic measures should be laid aside; in fact it is quite possible that the deplorable state in which the patient now finds himself is in part due to the "vigour" of the treatment already practised. As a rule these cases when treated on the lines indicated above do well, and when the inflammation subsides the psoriasis also is found to have disappeared. But it may come back some day.

INCOME TAX.

"J. P." has not in the past claimed the deductions he might have done in connexion with the expense of replacing carriages or motor cars. He has just sold a car for £100 and bought a new car for £450. What can he claim as a professional expense?

* * The only amount legally claimable is the excess of the cost of the car sold over the £100 allowed for it. The fact that he has paid too much income tax in the past does not, unfortunately, affect the amount to be allowed now.

"M. S." has been refused by the local inspector any deduction for subscriptions to the British Medical Association and a local medical society on the ground that those bodies have not entered into the arrangement with the Board of Inland Revenue.

* * In this connexion "M. S." has referred to the note appearing in our issue of April 1st (p. 531). As was explained there, "M. S." can legally claim only that proportion of his subscription which was expended in ways which would render the expenditure allowable for income tax purposes. One practical suggestion is that that proportion would include at least the probable cost of all professional literature supplied gratis, but the only real proof lies in production of the accounts of the association or society showing the total receipts and expenditure—a procedure which may not always be practicable.

LETTERS, NOTES, ETC.

DIAGNOSTIC SHOULDER STRAPS.

Mr. M. C. WALSHE (Manager, Mental Nurses Association, 8, Hindo Street, Manchester Square, W.1) writes to call attention to the significance of certain proposals of the Registration Committee of the General Nursing Council. This Committee has suggested that there should be distinctive letters, to be worn on shoulder straps, for all nurses on the general and supplementary parts of the Nursing Register, such as R.M.N. (registered mental nurse) and R.F.N. (registered fever nurse). This correspondent suggests that as soon as the meaning of these symbols becomes generally known a patient recovering from an acute infective fever, who seeks a health resort accompanied by his nurse, will have the nature of his recent malady revealed to the unsympathetic eyes of the hotel keeper and the other guests, while patients suffering from ailments of a mental or nervous kind will, when accompanied by a uniformed nurse, suffer a like disadvantage. We understand, however, that at the last meeting of the General Nursing Council for England and Wales the question of the distinctive letters to be adopted was referred back to the Registration Committee, so that the whole matter is still under consideration.

MEDICAL GOLFING SOCIETY.

THE summer meeting of the Medical Golfing Society was held on June 8th at Stoke Poges. The meeting was most successful, largely due to the excellent arrangements made and the splendid condition of the course. There were about eighty entries, and the results were as follows:

The *Lancet* Challenge Cup: H. Gillies and P. Kolesar, tied at five up. The Henry Morris Cup and Gold Medal: H. Gillies and P. Kolesar, tied at five up.

Class I.—First and second prizes: H. Gillies and P. Kolesar tied at five up. Best last nine holes: R. H. J. Swan, four up.

Class II.—First prize: W. Jagger, three up. Second prize: H. Davies, two up. Best last nine: A. Fiddowes and P. Coffey, one down.

Foursomes.—First prize: E. Grogono and G. C. Welby, one up. Second prize: G. Dawson and P. Kolesar. Sir R. Cruise and F. D. S. Jackson tied at all square.

A FLEA TRAP.

WE find in *La Chronique Médicale* for June an account of a flea trap devised by a French army medical officer. It is only applicable to a barely furnished room, since fleas will not be induced by it to leave comfortable quarters in cushions or rugs. A plate is placed on the floor and some oil poured into it. In order to save the oil water may first be put in the plate and the oil floated on it; then a nightlight is placed in the centre of the oil and lighted. The room must be otherwise completely dark, whereupon, it is said, fleas will be attracted by the flame, and jumping to reach it will fall into the oil and die. In this way, the medical officer from whom we are quoting states, he has caught as many as 500 fleas in a night.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 26, 27, 30, 31, and 32 of our advertisement column, and advertisements as to partnerships, assistantships, and locum tenencies at pages 28 and 29.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at pages 255 and 256.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 9 0
Each additional line	0 1 6
Whole single column (three columns to page)	7 10 0
Half single column	3 15 0
Half page	10 0 0
Whole page	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 429 Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive or retain letters addressed either in initials or numbers.

EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

590.

Cholera.

MUTERMILCH (*Ann. de l'Institut Pasteur*, April, 1922) gives an interesting account of the epidemic of cholera in the Polish army in 1920-21, and describes the way in which the disease was spread and the manner in which it was stamped out. His experiences lead to the following conclusions: Cholera was spread in Poland by direct contact from case to case, and not disseminated by contaminated water, for the water supply was examined bacteriologically with particular care in all the centres of infection, with negative results. Every new outbreak could be traced to the arrival of some infected convoy of prisoners or to a cholera carrier, and when the movement of prisoners was suspended no new centres of infection appeared and the epidemic was rapidly stamped out. The isolation of suspects and the quarantine of contacts came to be regarded as measures of the first importance. Healthy carriers of cholera were frequently encountered, and it was necessary to isolate them and also all contacts until three successive examinations of faeces had been reported negative. Prophylactic vaccination is a valuable measure in the campaign against cholera, although in Poland the sanitary condition and general health of the prisoners was so bad that little could be expected by such means. Experience pointed to the necessity of mobile bacteriological laboratories capable of proceeding at once to any new infected area for the purpose of investigating the source of the infection and isolating all carriers and suspects. Since the establishment of laboratories on the frontier for examining all prisoners being exchanged between Poland and Russia there has been no new epidemic in Poland, although Russia is still ravaged by cholera, there having been 80,000 cases of cholera reported in Russia in October, 1921.

591.

Intermittent Sinus Acceleration.

DE MEYER (*Arch. des mal. du coeur*, March, 1922) describes a special form of sinus arrhythmia characterized by an alternation of accelerated and normal or only slightly accelerated beats. This form of acceleration is absolutely independent of respiration, and the duration of the systoles is not shortened during the periods of acceleration. The amplitude of the pulse is not necessarily diminished, but is unequal during the normal and accelerated periods. The minimum blood pressure is normal, and the maximum pressure is much reduced, indicating that too small a quantity of blood is driven with sufficient force into a peripheral vascular system of normal size. On orthodiagraphic examination the heart is always found to be reduced in all its diameters. On clinical examination the patients with this form of arrhythmia were always found to present distinct signs of hypothyroidism. The latter condition entails a state of lowered excitability and fatigue of the acceleration system, which accounts for the alternate slowing and acceleration observed. The proof that this form of arrhythmia does not result from hypotonus of the vagus is furnished by the fact that stimulation of this nerve (by cervical compression or injection of physostigmine) does not check the arrhythmia. Treatment by thyroid extract combined with cardiac tonics considerably reduces the acceleration if it does not cause it to disappear entirely. Intermittent sinus acceleration is therefore a cardiological symptom characteristic of hypothyroidism associated with cardiac maldevelopment.

592.

Icteric Dermographia.

SCHÜRER (*Deut. med. Woch.*, May 5th, 1922) describes a phenomenon which, in the subjects of dermatographia, is a simple and dramatic sign of jaundice in an early stage. The patient in whom this phenomenon was observed was a man of 53, who for the previous fortnight had suffered almost daily from short attacks of violent abdominal pain. After scratching an eczematous patch on his right forearm he noticed that bright yellow stripes remained. Similar stripes were evoked elsewhere simply by scratching. On examination the skin was found to be pale and without a trace of jaundice except where sharply defined, not raised, bright yellow 1/2 cm. wide stripes were seen on both arms, the skin of which was quite intact. The patient had only one eye, and the sclera of this was jaundiced. The urine contained urobilin and was dark yellow, but it contained no albumin or sugar. There was a circumscribed area of tenderness and resistance in the region of the gall bladder. This was evidently a case of gall stones with commencing jaundice.

Without mechanical dilatations of the capillaries of the skin by scratching, the concentration of bile pigment in the tissues was not high enough to allow of general discoloration of the skin. Experimenting in this case, the author found that scratching the skin with a fingernail left an intensely red, raised stripe with pale margins. After two to three minutes the red colour disappeared, giving place to a raised canary-coloured stripe. In five to ten minutes the skin was no longer raised, but the yellow colour persisted; letters written on the skin with a fingernail were easily legible from one end of a large room to another. In this connexion the author refers to an observation by Strashburger, who noticed that when Weil's disease was associated with urticaria the urticarial area was more jaundiced than the normal skin. In the subjects of dermatographia the author's test should prove a useful and rapid method for demonstrating jaundice which has not become severe enough to discolour the skin. The explanation of this phenomenon is the following: the capillaries of the skin being dilated by scratching, blood plasma, containing bile pigments, escapes into the skin, from which it returns to the general circulation, leaving the bile pigments behind.

593.

Ascites in Chronic Malaria.

BARINETTI (*Arch. di patol. e clin. med.*, March, 1922) has seen 9 cases of chronic malaria which were characterized by chronic entero-colitis, with ascites and cirrhosis of the liver, and considerable enlargement of the spleen. Two other patients, who were not suffering from malaria, presented the same clinical picture. Barinetti comes to the conclusion that in all these cases the cirrhosis of the liver, and perhaps some of the changes in the spleen, are not due to malaria, but are produced by some infection which is probably due to the tubercle bacillus or pathogenic organisms in the intestine. Barinetti is of opinion that the symptoms, described by several writers under the name of Banti's disease, of malarial origin are really examples of the type which he has described.

594.

Mycotic Intertrigo.

DUBREUILH and JOULIA (*Ann. de Derm. et de Syph.*, April, 1922) describe an erythematous condition of the folds of the skin due to a yeast-like organism, the lesions of which can be clearly distinguished from other better known manifestations of intertrigo. The thigh is the most common site for this infection, which causes a smooth, deep red plaque covered with thin epidermis, often moist but showing no desquamation, of irregular outline, and surrounded with a thin ring of desquamating skin. In the neighborhood of the main lesion are small islands of inflammation of similar character. Other regions of the body, such as the axillae and the folds below pendulous mammae, may be similarly attacked. The chief symptom is intense itching, worse at night, and aggravated by warmth or friction. The diagnosis is made by the examination of scales from the edge of the lesion in liquor potassae, when the characteristic tangled mycelium and exogenous spores will be seen; cultures should be made on Sabouraud's maltose agar, when colonies of the fungus resembling staphylococci are obtained. The disease is best treated with an ointment containing benzoic acid 3 per cent. and salicylic acid 3 to 6 per cent., the application of which causes much smarting at first, but after a few days no further pain is complained of and the inflammation subsides. The relief is considerable after the second day, and the lesion is usually healed in two or three weeks. Chrysorubin and dilute iodine may also be used.

595.

Small-pox and Flies.

HUNZIKER and REESE (*Schweiz. med. Woch.*, May 18th, 1922) give an account of an outbreak of small-pox in Basel between March and August, 1921. There were altogether forty-six cases, with eight deaths. In several cases it proved impossible to trace the source of infection; these cases had not even been in contact with cases of variella. In many cases there was not even a possibility of the disease having been conveyed by healthy carriers. One patient was an epileptic who had been interned for several years in an institution, and none of the few persons with whom he came in contact had been even under suspicion of small-pox. The pungent smell associated with small-pox attracted swarms of flies to the patients, and several of the persons who contracted the disease were of an apathetic temperament and more or less incapable of keeping flies off their bodies. The greatest number of cases which could not be traced to known sources of infection occurred during the warm days of July when

flies were very numerous. These observations having associated the spread of small-pox with flies, fly-proof windows were introduced wherever small-pox cases were isolated, and three weeks later the epidemic died out. The authors confirm the observations of earlier writers as to the rarity with which small-pox proves infectious during the incubation or prodromal period of the disease. Early isolation is therefore almost invariably successful in preventing further spread of the disease.

595.

The Nervous Child.

O. HEUBNER (*Klinische Wochenschrift*, May 13th, 1922) considers that the ultimate definition of neurasthenia is not quite satisfactory, and that, in the majority of cases, treatment can only arrest a pernicious tendency or improve the environment. These children react abnormally in conditions that would otherwise be pleasant and healthy. He gives details of many neurotic children of both sexes, ranging in age from infancy to puberty. In a number there was a family history of functional or of organic disease, including syphilitic nervous disease; in others, the onset dated from an acute infection—*influenza*, intestinal catarrh, diarrhoea, measles, etc. The commencement of school life is a critical period, and plays an important part in causation. The majority of patients suffered from non-neuralgic headache, mental depression, sometimes amounting to stupor, sleeplessness, loss of appetite, vomiting (sometimes of the "cyclical" type). Others had tender spots and hyperaesthetic areas in various regions of the head, trunk, and limbs, with increased tendon reflexes. Several suffered from "night terrors," somnambulism, nocturnal enuresis, and in two cases incontinence of faeces. Frequently the symptoms were so ambiguous that diagnosis presented great difficulty, and in one case ileus was diagnosed, a laparotomy was done, violent peristaltic action of the small and large bowel was seen, but there was no obstruction; the author considers that the increased peristalsis was due to "vagotonic action." Shortly after the healing of the operation wound, severe vomiting recurred and was treated by internal medication. Acetonuria was found in some cases of "cyclical" vomiting. Several boys showed signs of sexual precocity or of perversion, and one of these subsequently became insane. The author recommends treatment on general principles, attention to personal and school hygiene, and removal of any possible source of irritation. Where patients have a persistent dread of school, or have hysterical manifestations in school, he recommends a year's absence, or that they be educated privately.

SURGERY.

597.

Osteitis Fibrosa.

YOUNG and COOPERMAN (*Annals of Surgery*, February, 1922) point out that this disease was first described in 1891 by von Recklinghausen. He showed that the pathologic changes within the bone and marrow were the results of chronic inflammation. The formation of fibrous tissue, bone cysts, and giant cell tumours are various phases of this affection. Two types of the disease are recognized: (1) a local osteitis fibrosa and benign bone cysts, dependent upon trauma in many instances; (2) a general form dependent on grave nutritional disturbances, where endocrinal malfunction, faulty calcium metabolism, or chronic infection seems to be of etiological significance. The formation of bone cysts is produced by a liquefaction of fibrous tissue, or giant-cell sarcomata of the epulis type may develop in these areas of metaplasia. These cells are large and contain many nuclei; they are not prognostic of malignancy, and are allied to the giant cells found in inflammatory regions. The femur, humerus, and tibia are most often affected, the disease starting at the ends of the bones. The joints are rarely invaded, but owing to the proximity of the tumours their function may be interfered with. As in tuberculosis of bone, the striking feature is the formation of fibrous tissue in which regeneration of bone is very limited. The symptoms may start with vague rheumatic pains. Fractures are very common, and may be spontaneous. The bones unite slowly, and fibrous union may result. Pain is not marked, whilst muscular atrophy is often present. Diagnosis is based on the long duration of the process, frequency of fractures, vague symptomatology, and x-ray examination. The bone is seen to be expanded and subdivided by trabeculae, and there is no sclerosis of surrounding bone. The prognosis is bad, and nothing in the way of cure is known; the local form may be benefited by curettage and bone transplantation. X rays and radium have been used with some success. Constitutional treatment is given for the general type. Death occurs from cachexia or intercurrent disease.

598.

Peritonitis.

HARDWICK SMITH (*New Zealand Med. Journ.*, February, 1922) discusses the important subject of peritonitis, particularly the type following acute appendicitis and the pneumococcal and tuberculous varieties. He does not consider peritonitis to be the fatal disease it was regarded some years ago. Acute appendicitis always starts with pain, and where pain is found associated with tenderness, inflammation of some viscus is present. In cases seen with acute peritonitis following acute appendicitis he advises that patients when admitted to hospital in this condition should not be operated upon immediately. They should be put to bed in the Fowler position, given morphine, and kept warm. Their condition will improve in a few hours, whereas if operation had been performed they would certainly have died. Operation is then carried out with gas and oxygen anaesthesia, the source of infection removed, and the pouch of Douglas drained. The bowels are left alone and no aperients or enemata given at first; morphine and rest are enforced and most patients recover. With regard to pneumococcal peritonitis, the encysted type has a good prognosis; when the peritonitis is diffuse the prognosis is bad and nearly always fatal. In most cases the onset is acute, often like acute pneumonia, but the temperature remains high. Many of the diffuse form should not be operated upon but left till it becomes encysted; these abscesses can then be evacuated and the patient recovers. Tuberculous peritonitis is usually associated with other tuberculous lesions, and the peritoneal infection is of a secondary character. The disease is generally chronic and originates in childhood. The ascitic cases improve greatly when submitted to operation; the other forms can be improved or cured by medical means alone. Rest and good diet, and perhaps x-ray administration, may be tried. Only when obstruction is present or diseased tubes or ovaries found should surgical aid be given.

599.

Post-Operative Ulceration of the Colon.

LECÈNE (*Bull. et Mém. Soc. Chir. de Paris*, April 11th, 1922) discusses a case where intestinal obstruction supervened fifteen days after a pelvic operation. He points out that there are three courses open for the surgeon to follow: (1) laparotomy and endeavouring to relieve the obstruction and re-establish the intestinal canal; (2) enterostomy made in a distended loop of intestine; (3) anastomosis "at a guess" between a dilated coil of small intestine and the colon below the obstruction. In the case he mentions the last course was adopted. Several months later the patient suffered from ulceration and haemorrhage of the colon, and subsequently it was necessary to undo the anastomosis. Since that time the patient has been cured completely. The operation of entero-anastomosis when performed between the lower end of the small intestine and a neighbouring coil of large intestine in cases of subacute obstruction appears satisfactory, and avoids the disadvantages of an enterostomy. When, however, the level of the anastomosis cannot be determined there are disadvantages, as this case proves. The term "peptic ulcer of the large intestine" should not be applied to this condition; peptic ulceration relates to ulcers situated anatomically near the stomach, and they are the result of peptic digestion. It is possible that in this case it was due to the action of the pancreatic juice on the mucosa of the colon. This case shows that an operation which has such obvious advantages in the treatment of post-operative intestinal obstruction possesses the possibility of serious complications.

600. Treatment of Spontaneous Rupture of the Bladder.

NICOLAYSEN (*Acta Chirurgica Scandinavica*, April 29th, 1922) records one of those cases in which the patient's refusal to submit to operation saves his life. A man, aged 47, suffering from syphilis of the central nervous system, developed violent pain in the lower abdomen and strangury, and he could not pass a drop of urine. On admission to hospital twenty-eight hours later, in almost moribund condition, catheterization of the bladder yielded 950 c.cm. of a fluid the albumin content of which was almost that of serum. There were no casts, and only a trace of urea (0.113 per cent.). The urea content of the serum was as high as 0.221 per cent. He refused operative treatment, and a catheter was secured in the bladder. Ultimately he recovered, and the author points out that, considering the high urea content of the serum and the patient almost moribund condition, a general anaesthetic and operation would have killed him. At present the mortality of cases operated on for rupture of the bladder is over 50 per cent., and the author's case, as well as three similar cases, has found in the literature, suggest that the old rule always to operate for rupture of the bladder may require revision in those cases in which there is evidence of serious uraemia.

601. Actinomycosis of the Tongue.

NEW and FIORI (*Amer. Journ. Med. Sci.*, April, 1922) find that actinomycosis of the tongue is usually characterized by the presence of a single isolated nodule in the anterior half of the tongue, often near the tip and varying from 1 to 1.5 cm. in diameter. The condition may be acute in onset with severe pain and throbbing and local tenderness, general malaise, and rise of temperature; or it may develop insidiously during the course of several months or even three or four years. The diagnosis is best made by microscopic examination of sections, for which purpose the whole nodule should be excised, since the characteristic granules are often not numerous. The usual picture of a diffuse, indefinitely outlined induration with multiple sinuses is not found in actinomycosis of the tongue, since in this locality the lesion is usually enclosed in a fibrous capsule, over which normal mucous membrane may be stretched as though covering a superficial cyst or a small abscess about to rupture. If the nodule is not too large wide incision with primary suture is the best form of treatment. For larger lesions the procedure should be drainage with curettage, followed by daily swabbing of the wound with tincture of iodine, packing with iodoform gauze, the administration of large doses of potassium iodide, and the use of radium. The prognosis is favourable in small lesions which can be completely excised, but less favourable in those cases in which there is a diffuse area, especially if it be near the base of the tongue, or if there be a definite abscess. Out of 127 patients suffering from actinomycosis examined in the Mayo clinic in twelve months in 66 the disease occurred in the head and neck, and in only 3 did it occur primarily in the tongue.

602. Congenital Dislocation of the Hip.

DELCHÉF (*Le Scalpel*, April 22nd, 1922) reports six cases of congenital dislocation of the hip reduced at ages much older than is usually practised. The ages were 36, 18, 23, 17, and 13½ years respectively. The results were surprisingly good, for although the anatomical position of the head of the femur was not always perfect the functional results were in every case decidedly beneficial. In the first case (a woman aged 36) there was much pain and lameness before operation, whereas afterwards she could walk without pain or fatigue, and the lameness was hardly noticeable. Most authors agree that where good effects follow operation the beneficial results are slow in making their appearance and tend to go on improving with exercise. Radiograms of the hip-joint in the author's cases are given.

OBSTETRICS AND GYNAECOLOGY.**603. Importance of Antisyphilitic Treatment during Pregnancy.**

BOAS (*Hospitaltidende*, May 5th, 1922) has examined 483 infants born in hospital to syphilitic mothers, and he tabulates his findings according as the mothers were or were not given specific treatment before the birth of the child. Of 153 mothers whose syphilis had not been treated before the birth of the child 157 gave birth to syphilitic children—that is, only in one case did the infant escape syphilis. Of 87 mothers treated with mercury before they became pregnant 78 gave birth to syphilitic children. Of 15 mothers who had been treated with salvarsan before they became pregnant 12 gave birth to syphilitic children. Of 111 mothers who had been treated with mercury during pregnancy 80 gave birth to syphilitic children. Of 79 mothers who had been treated with salvarsan during pregnancy 19 gave birth to syphilitic children. Of 26 mothers who had been treated with salvarsan before, and with mercury during, pregnancy 7 gave birth to syphilitic children. Of 7 mothers who had been treated with salvarsan both before and during pregnancy only one gave birth to a syphilitic child. The author concludes that every syphilitic woman should be treated with salvarsan during pregnancy, even when her infection dates back a score of years and she gives a negative Wassermann reaction during pregnancy.

604. Hydatidiform Mole and Chorion-epithelioma.

ACCORDING to SCHWEITZER (*Zentralbl. f. Gynäk.*, May 6th, 1922), hydatidiform mole has been found, in 57 cases at the Leipzig clinic, to occur more frequently in multiparae (18 per cent.). Expulsion of the mole occurred at any time up to the seventh month, most frequently (38 per cent.) in the fourth month. The most striking symptoms are blood-stained discharge, disparity between the duration of amenorrhoea and the size of the uterus, absence of foetal heart sounds, albuminuria, and oedema; occasionally expulsion of vesicles clinches the diagnosis, or these may be found by examination in water or saline solution of the presenting uterine contents

removed by forceps. Prognosis, even apart from the possible advent of chorion-epithelioma, is grave; the series recorded showed a 10 per cent. mortality, in which sepsis, severe haemorrhage, or both in combination, were the chief factors. The most important principles of treatment consist in avoidance of haemorrhage and in securing speedy evacuation of the uterus, spontaneously whenever possible. To remove the whole or a portion of the contents of the uterus digitally is often unavoidable. In the Leipzig cases pyrexia followed in one-half and severe secondary haemorrhage in one-quarter of the cases. Cases of chorion-epithelioma encountered in the same period as the 57 cases of mole numbered 5, of which 2 were associated with the former affection. The greatest possible differences are found in the degree of malignancy shown in different cases, and unfortunately there is no means of foretelling the probable course in any particular case. Apart from total hysterectomy—the operation of election—x-ray treatment has had certain recorded successes.

605. Gonococci in the Preputial Folds.

CLODI and SCHOPPER (*Wien. Klin. Woch.*, March 2nd, 1922) examined 42 cases of gonorrhoea in women aged from 16 to 58 in whom the disease had lasted from three days to six years and after exclusion of 7 completely negative cases found gonococci in the secretion of the preputial folds in 26 out of 35 cases, or in 74.3 per cent. It was noteworthy that in four cases in which gonococci were present in the preputial secretion bacteriological examination of the urethra and vagina was negative. The writers conclude that the presence of gonococci in the preputial secretion plays a considerable part in the persistence of contagion and reinfection of the patient's own genitalia. An efficient treatment for gonorrhoea in women must therefore include a mechanical cleansing and disinfection of the preputial folds as well as a systematic bacteriological examination of the preputial secretion.

606. End-Results of Treatment of Cancer of the Uterus and Vagina.

GIESECKE (*Arch. f. Gynäk.*, February 16th, 1922) records 27.7 per cent. of lasting (five years') cures among 371 cases of uterine cancer treated from 1910 to 1916 at the Kiel Universitäts-Frauenklinik. Cases of cervical cancer numbered 350, with 26.6 per cent. of lasting cures, and of corporeal cancer 21, with 10 cures. The 243 operable cases of cervical cancer were treated by scraping and cauterization, followed immediately by operation, which was abdominal in 224 instances; cures numbered 35.4 per cent., and primary mortality in cases operated on by Wertheim's method was roughly 19 per cent. The average percentage operability for cervical cancer during the seven years was 69 per cent.; it was found by analysis of the figures for various years that by operating at relatively more advanced stages of the disease the primary mortality became increased without any compensation in attainment of an increased proportion of five years' cures. It is noteworthy that in 224 cases of extended abdominal hysterectomy glands microscopically proved to be carcinomatous were present in 47, of which 10 afterwards showed five years' cure. Among 60 inoperable cases of cervical cancer treated by combined x-ray and radium applications, five years' cure was attained in 8.3 per cent. Only one of the 11 cases of vaginal cancer was free from recurrence at the end of five years.

607. Yeast in the Treatment of Leucorrhoea.

STEINWEG (*Deut. med. Woch.*, May 5th, 1922) has revived at his hospital a treatment introduced more than twenty years ago by Landan for leucorrhoea. It consists of introducing a piled teaspoonful of dried yeast (*levurirose*) into the vagina after it has been swabbed dry with cotton-wool. The vagina is then plugged with a tampon, which is removed twenty-four hours later. The treatment is repeated two or three times a week at first, and as improvement occurs the intervals between each application are prolonged. The cases treated were not gonorrhoeal, and leucorrhoea due to comparatively remote lesions and to catarrh of the cervix was also not subjected to this treatment. The author does not publish a statistical analysis of his results, but contents himself with the generalization that this treatment proved very effective in a large proportion of cases. Bacteriological control of the vaginal flora showed that the luxuriant growth of cocci was greatly checked in many cases, cocci largely giving place to the bacilli of the healthy vagina. Side by side with this bacteriological improvement there was a definite and early abatement of the clinical symptoms, and in the majority of cases prompt recovery was not followed by relapse. But there were some cases in which the leucorrhoea was diminished but not cured, and in these cases no further improvement could be effected by douching with astringent solutions. Probably these cases were due to constitutional disabilities.

such as disordered action of the ovaries or chlorosis, which require general rather than local treatment. The author, who is attached to Professor Pinkuss's gynaecological hospital in Berlin, lays great stress on the variety of the causes of leucorrhoea, and he insists that uniform success can be achieved only by basing treatment on complete knowledge of the etiology of leucorrhoea.

608. Births during War Time.

DÁVID (*Zentralbl. f. Gynäk.*, May 20th, 1922), from examination of children born during the war at the Universitäts-Frauenklinik in Budapest, where from 1,400 to 2,000 births take place annually, concludes that neither stillbirths nor premature births increased during the war. The proportion of male to female children did not vary from that obtaining during peace. No increased mortality among the newborn was perceptible. The average weight was found to be diminished during war time, especially during the last three years; the average dimensions also showed a decrease, which was about 3 per cent. in length and 1 per cent. in the circumference of the head. These diminutions were not traceable to a shortening of the average duration of pregnancy.

PATHOLOGY.

609. Reaction of the Blood in Dyspnoea.

FRASER, ROSS, and DREYER (*Quart. Journ. of Med.*, April, 1922) have applied the method of Dale and Lovatt Evans to the determination of the reaction of the blood in normal individuals, in patients suffering from heart failure with valvular disease, and in cases with severe disturbance of kidney function. They found that the average reaction of the arterial blood in healthy individuals is P_H 7.68, the limits in health being from P_H 7.72 to P_H 7.64; the reaction of venous blood is approximately the same as arterial. In cases of heart failure with valvular disease the blood is more alkaline than normal, but the degree of alkalaemia does not appear to have any close relationship to the severity of the clinical condition, and cases with severe respiratory distress and those with little or no distress alike have a blood reaction which is more alkaline than in health. In severe renal disease a condition of acidaemia was found often associated with respiratory distress. Pronounced acidaemia may therefore be present without dyspnoea; on the other hand, dyspnoea may be found associated with alkalaemia, as in valvular disease, or in acidaemia, as in renal disease. Reactions of arterial blood as alkaline as P_H 7.95 and as acid as P_H 7.37 are compatible with life.

610. Variations in the Antibody Content of the Serum in Phthisical Patients.

ARMAND-DELILLE, HILLEMANN, and LESTOCQUOY (*C. R. Soc. Biologie*, April 8th, 1922) have estimated the antibody content of the serum in a series of twenty patients suffering from pulmonary tuberculosis. Re-examination of each serum was made at varying intervals during the course of the following few months. The test employed was the complement-fixation reaction, and the results are given in terms of the number of doses of complement fixed by 1 c.cm. of serum. Three points of interest emerge from the table. First, in no fewer than 35 per cent. of the cases was a positive reaction followed by a negative one at the next examination; this shows that a single negative result is of little or no value. Secondly, considerable fluctuations occurred in the antibody titre from month to month without any corresponding alterations being observed in the condition of the patient; this but adds confirmation to the already established fact that there is no definite correlation between the quantities of humoral antibodies and the degree of immunity. Thirdly, very marked modifications of the clinical state of the patients occurred without simultaneous variations in the antibody titre. If these results can be corroborated the complement-fixation test for tubercle will be deprived of a considerable amount of its value, for not only is it an unreliable test for purposes of diagnosis, but it appears to be equally valueless for estimating the success of the treatment afforded to the patient. In both these respects it is in distinct disagreement with the Wassermann reaction in syphilis, which both from a diagnostic and a therapeutic point of view seems to become daily of greater and greater importance.

611. Indican in the Blood in Renal Disease.

ACCORDING to SNAPPER and VAN VLOTEN (*Klinische Wochenschrift*, April 8th, 1922), indican was first detected in the blood serum of uraemic patients by Obermayer and Popper, who found that death followed rapidly in almost all patients showing well-marked indicaemia. More recently Haas and

also Rosenberg, using more sensitive tests, have found indican in the serum of healthy subjects. The former workers' estimate that amounts up to 1.4 mg. per litre may occur in the serum of patients with normal renal function is said to be accurate. The blood indican is slightly increased in association with intestinal stasis, as in cases of ileus or peritonitis, but in cases of uraemia there is very considerable retention amounting sometimes to thirty or sixty times the normal amount. Snapper and Van Vloten find that in cases of acute nephritis with long-standing azotaemia increase of the blood urea is usually associated with hyper-indicaemia; when occasionally the latter sign occurs in the absence of the former an exceptionally grave prognosis is indicated. The prognostic value of estimation of the blood indican is greater than that of urea in that it is less influenced by a diet poor in protein. The technique described is comparatively simple and requires much less time and skill than are needed for estimation of the nitrogen fraction in the blood serum. The test is inapplicable if the patient has been receiving iodides.

612. Haemophilic Bacilli.

RIVERS (*Bull. Johns Hopkins Hospital*, April, 1922) finds that all haemophilic bacilli are not alike in their nutritional requirements as regards the so-called accessory factors for growth. *Bacillus influenzae* requires the presence of separate factors, one resisting the temperature of the autoclave, the other being destroyed in the autoclave. Solution of these autoclave-labile and autoclave-stable factors was prepared, the former by filtering a suspension of antityphoid yeast cells, and the latter by precipitating haematin from red blood corpuscles. By the addition of one or both of these solutions to standard media it was possible to test the nutritional requirements of haemophilic bacteria, and it was found that *B. pertussis* requires neither of the growth accessory factors, whereas haemolytic and non-haemolytic influenza bacilli require both. Fildes, who carried out similar experiments, using a peptic digest of blood, concluded that the combined oxygen, probably in the form of a peroxide, was activated for the influenza bacillus by the catalytic action of the iron in the blood pigment, an interaction of the two parts of the digest being necessary for the growth of the influenza bacilli. Rivers concludes from his observations that there is no definite proof of interaction, for some haemophilic bacteria require one accessory factor, others require both, and *B. pertussis* can grow in the absence of either.

613. Experimental Researches on Diabetes Insipidus.

To test the conclusions of Camus and Roussy that diabetes insipidus and the condition of dystrophia adiposo genitalis are in reality due to a lesion of the parafundibular region of the brain and not to an affection of the pituitary, BAILEY BREMER (*C. R. Soc. Biologie*, May 6th, 1922) have carried out a series of twenty-four experiments on dogs, in which puncture of the hypothalamic area was performed by the temporal route. They find that as a result of even the smallest puncture polyuria sets in in the course of a day or two; it is characterized by all the properties of that seen in diabetes insipidus in the human being—namely, the power of renal concentration under conditions of deprivation of water, fever, and injection of pituitrin, the diuretic effect of chlorides, and the failure of action of theobromine. If the lesion produced be somewhat more extensive caecoxia may set in, accompanied by general atrophy and adiposity. Moreover, they find that the polyuria is independent of the nerve supply of the kidney; in fact, the nerves to this organ may be cut without preventing the onset of the condition or of arresting it once it has set in. This being so it is difficult to understand how the effect is produced as a result of a simple lesion of the brain tissue; they are quite emphatic, however, in denying the possibility of its association with the pituitary body.

614. The Thyroid Gland and Immunity.

SESTINI (*Lo Sperimentale*, Ann. 76, fasc. 1-3) has carried out a series of experiments on animals with a view to determining what part if any the thyroid gland takes in the processes of immunity. He took 15 animals, used 4 as controls and vaccinated 11 against typhoid. The vaccinations were made in the peritoneum at intervals of about a week. When examined later the thyroid was found to be in a condition of hyperfunction, with an increase in lipoids, in fusine granules, and changes in the colloid—a true state of angiectoid hyperplastic struma. It is difficult to say whether the thyroid formed antibodies, but the hyperplastic state points to an increase in the internal secretion of the gland from hyperproduction of hormones, which through the nervous system might act on the cells of different organs at a distance.

USE YOUR CAR WHILST WE ARE SELLING IT FOR YOU.

¶ You may or may not be desirous of selling your car at present, but doubtless it would be very acceptable to you to be provided with opportunities to sell it at a price you yourself consider favourable. Our organisation makes this possible, and the only cost to you is a registration fee of one guinea per annum.

¶ As a member of the medical profession, whose calling imposes daily use of a car under all weather conditions, you will realise that a "new car every year" is a resolve, ideal in theory, but not so easy to put into practice. Our organisation and continuous service make this possible. It enables you to sell your car at your own price, and to get another new car when it is most convenient for you to do so.

¶ Safeguard yourself against the undue depreciation of your car by registering particulars of it with us, when we will keep you advised from time to time of prospective purchasers at your price, leaving it to you to communicate with them if you wish.

¶ A registration form and full particulars will be sent post free per return upon request.

OVERFATNESS

Dr. WILLIAM T. CATHELL'S TREATMENT.

Reliable and Harmless.

Doctors are frequently asked by their patients for something to make them thinner, and Dr. WILLIAM T. CATHELL'S method shows how this may be done safely and gradually.

A verbatim copy of a Lecture, by William T. Cathell, A.M., M.D. Baltimore, on Overfatness, will be sent free on application to

ALFRED BISHOP, Ltd., Manufacturing Chemists, **48, SPELMAN STREET, LONDON, E. 1.**

PNEUMOSAN IN TUBERCULOSIS.

In every stage of Tuberculosis, where no impression can be made with routine or any other known treatment, use Pneumosan (Amyl-thio-trymethylanine), a homogeneous chemical substance, with a clinical record of 10 years. Pneumosan is well tolerated and has rapid inhibitory action; it is alternative and phagocytic. Well indicated in early and advanced cases and considered by a large number of Physicians to be the most reliable therapeutic agent in every type of Tuberculosis.

The Medical Superintendent of Birmingham General Dispensary, writes: "During a period of 18 months I treated 103 cases of Pulmonary Tuberculosis. A large number were in a very advanced stage owing to the fact that Pneumosan was tried as a forlorn hope, where no other treatment seemed applicable. I obtained most striking results in early as well as in very advanced cases. A great point in its favour is that I have never known any untoward effect to follow its administration."

Pneumosan is issued in vials containing 20 injections at 15/6 and in boxes of 10 ampoules at 10/.

Projection-Drawing Apparatus, Prismatic Binoculars, etc.

DIABETIC FOODS

Recent research in the treatment of diabetes has been productive of much, new data.

Unfortunately the knowledge acquired has had little practical value for the general practitioner. The limitation of starchy foods and sugar, within the tolerance of the patient, remains the principal factor in treatment.

CALLARD & CO. maintain the high standard of their products, which has always distinguished them.
